**MILLER, WILLIAM EDWARD** (1914– ), U.S. political figure, was born in Lockport, N.Y., on March 22, 1914. Following his graduation from the University of Notre Dame, Notre Dame, Ind. (1935), and Albany (N.Y.) Law school (1938), he practised law in Lockport and in 1940 was appointed U.S. commissioner for the western district of New York. In 1942 he entered the U.S. army and, after serving with the military intelligence branch, attended officer candidate school. Assigned as a first lieutenant to the war crimes section of the judge advocate general's office in 1945, he served as assistant prosecutor at the Nürnberg war crimes trials. After his return to civilian life, Miller served as assistant district attorney and district attorney of Niagara county, N.Y., and in 1950 was elected to the U.S. house of representatives. Reelected six times, he became a spokesman for the conservative wing of the Republican party and was known for his effective, often biting, criticism of the Democratic opposition. As chairman of the national Republican congressional committee in 1960, Miller played an important part in the campaigns of that year which resulted in an increased Republican house membership despite the election of a Democratic president. In 1961 Miller was named chairman of the Republican national committee and in 1964 he became the Republican vice-presidential nominee on the ticket headed by Sen. Barry M. Goldwater. After a campaign, described as one of the bitterest in modern U.S. history, the Goldwater-Miller ticket was overwhelmingly defeated.

**MILLERAND, ALEXANDRE** (1859–1943), French lawyer, politician and president of the republic, was born in Paris on Feb. 10, 1859. He was educated for the bar, and made his reputation by his defense of the instigators of the strike at Decazeville in 1883. He was elected to the chamber of deputies for the *département* of the Seine in 1885 as a Socialist. He became chief of the Socialist left, which then mustered 60 members, and edited until 1896 their organ in the press, *La Petite République*. When in June 1899 he entered Waldeck-Rousseau's cabinet of "republican defense" as minister of commerce he limited himself to practical reforms, devoting his attention to the improvement of the mercantile marine, to the development of trade, of technical education, of the postal system and to the amelioration of the conditions of labour. He was bitterly denounced by many Socialists as a traitor, for agreeing to participate in a nonsocialist government along with men hated by the workers.

He was a fierce opponent of the Combes ministry, which succeeded that of Waldeck-Rousseau, for he objected to its narrow anticlericalism. In July 1909 he became minister of public works in Briand's first cabinet, his principal achievement being the reorganization of the state railways. Together with Briand he took strong measures to suppress the railway strike of Oct. 1910. In Jan. 1912 he was appointed minister of war under Raymond Poincaré. He reorganized the higher command, and gave a definite status to military aeronautics for the first time. On Aug. 25, 1914, he was invited by Viviani to become minister of war. Accused, however, of being too slow in providing the necessary heavy artillery, he resigned with the other members of the Viviani cabinet at the end of Oct. 1915. In 1918 he was elected a member of the Académie des Sciences Morales et Politiques.

On the resignation of Clemenceau, Jan. 18, 1920, Millerand formed a cabinet, and became prime minister and minister for foreign affairs. His main activities were in regard to the application of the treaty of Versailles. He was present at the inter-Allied conferences at San Remo and Spa in 1920. In May 1920 he frustrated attempts to organize revolutionary strikes. He did much to supply matériel to Poland during the Polish-Soviet war.

In Sept. 1920 Deschanel, president of the republic, was forced by ill-health to resign. Millerand was elected as his successor. During his candidature he made no secret of his wish to strengthen the power of the president by a revision of the constitution. Millerand's conception of the role of president of the republic brought him into collision with the Radical and Socialist majority, which, under the name of the *cartel des gauches*, was successful in the elections of May 11, 1924. He was violently attacked by the Radical and Socialist press, which accused him of having exceeded his powers by intervening in the party struggle, and called for his resignation. Herriot, the leader of the *cartel des gauches*, when asked by Millerand to succeed Poincaré as premier, announced that he would do so only on Millerand's resignation.

Millerand therefore invited the senator François-Marsal, who had been his minister of finance in 1920, to form a cabinet. His government, however, was immediately defeated; and Millerand tendered his resignation.

In Jan. 1927, at the senatorial elections in the *département* of the Seine, Millerand was defeated. Several months later he stood for a by-election in the *département* of the Orne, in Normandy. He was elected and resumed his place in the senate. He remained a controversial figure in French politics, too independent in mind

to please any party. Among his published works are *Le Socialisme réformiste* (1903) and *Pour la défense nationale* (1913). He died at Versailles, France, April 7, 1943.

*See* R. Persil, *A. Millerand* (1949). (D. Ts.)

**MILLERITE,** a mineral consisting of nickel sulfide, NiS. It is a minor ore of nickel. Millerite crystals belong to the rhombohedral system and have the form of slender needles arranged in divergent groups or of delicate fibres loosely matted together ("hair-pyrites"). The colour is brass yellow and the lustre metallic. Millerite was named for mineralogist W. H. Miller.

**MILLER'S-THUMB,** any of several small fishes of the genus *Cottus*, abundant in rivers and lakes of northern and central Europe and North America where there is clear water and gravelly bottom. Unlike most members of the sculpin family (Cottidae), miller's-thumbs are confined to fresh water. The names bullhead (more properly applied to certain catfishes) and sculpin (usually given to marine cottids) are often used for miller's-thumbs. The head is broad and flat; the body rounded and scaleless with large pectoral and narrow pelvic fins, and two dorsal fins. The gill cover is armed with a spine.

The European species (*C. gobio*) is usually three to five inches long. The common species of eastern North America, *C. bairdi*, *C. carolinae* and *C. cognatus*, also called mottled, banded and slimy sculpins, respectively, seldom exceed four inches. The prey consists of small aquatic animals, upon which the fish pounces from some refuge. The female deposits her eggs in a cavity under a stone, and the male watches and defends the eggs until the young are hatched. (C. Hu.)

**MILLES, CARL** (originally Vilhelm Carl Emil Andersson) (1875–1955), Swedish-U.S. sculptor, designer of decorative fountains and memorial monuments in Sweden and the United States, was born in Uppsala, Swed., June 23, 1875.

In 1902, during student years in Paris, Milles won recognition through the competition for the Sten Sture monument at Uppsala (completed 1925). His style, at first impressionistic under Auguste Rodin's influence, became more abrupt and formal under successive influences of medieval art and early Greek art, and later showed more fluent patterns within individual figures and among the parts of his elaborate compositions. Milles worked in clay (for casting into bronze), stone and wood. His first major fountain, "Europa" in Halmstad, Swed. (1926), has the elements of spacious design, subtle water effects and inventive figure types (such as the fusion of classical triton or faun with Nordic goblin or troll) which also characterize his "Orpheus" fountain in Stockholm (1936) and the "Meeting of the Waters" in St. Louis, Mo. (1940). Milles' reputation spread with exhibitions at the Tate gallery, London (1926–27), and the City Art museum, St. Louis (1931). In 1931 he became head of the department of sculpture at Cranbrook Academy of Art, Bloomfield Hills, Mich. He became a U.S. citizen in 1945.

CARL MILLES' FOUNTAIN "EUROPA AND THE BULL," MILLES VILLA, LIDINGÖ, NEAR STOCKHOLM

Milles' works were collected at Cranbrook, his home for 20 years, and at the Milles villa, now a museum, in Lidingo, near Stockholm. Stockholm has over 20 Milles monuments, and notable examples of his work are in Detroit, Mich., Chicago, Ill., St. Paul, Minn., Harrisburg, Pa., Falls Church, Va., Wilmington, Del., and New York city. His "Agnippe" fountain was set up in the New York Metropolitan Museum of Art shortly after his death at Lidingo on Sept. 19, 1955.

*See* Meyric R. Rogers, *Carl Milles, an Appreciation of His Work* (1940). (Ja. W. F.)

**MILLET, FRANCIS DAVIS** (1846–1912), U.S. painter, illustrator and writer, was born at Mattapoisett, Mass., on Nov. 3, 1846. He was a drummer boy with the Union forces in the Civil War, graduated from Harvard college in 1869, and in 1871 entered the Royal Academy of Fine Arts, Antwerp. During the Russo-Turkish War of 1877–78 he was a correspondent for several newspapers, and was decorated twice by the Russian government. On his return he was made a member from the United States of the international art jury at the Paris exposition of 1878. He was director of decorations at the Columbian exposition, Chicago, 1893, and in 1898 went to Manila as war correspondent. Millet was a passenger on the "Titanic" when it sank on April 15, 1912; he was last seen urging women and children into lifeboats.

In 1850 Millet became a member of the Society of American Artists, and in 1885 was elected to the National Academy of Design, New York. He was a trustee of the Metropolitan Museum of Art, secretary of the American Academy in Rome and vice-chairman of the Fine Arts committee. His work as a decorative artist may be seen at Trinity church, Boston; the Bank of Pittsburgh, and the capitol at St. Paul, Minn. His pictures are in many public collections, among them being "A Cosy Corner" in the Metropolitan Museum of Art, New York, and "Between Two Fires" in the Tate gallery, London. Millet also wrote essays and short stories, and an English version of Tolstoi's *Sebastopol* (1887). Among his publications are *The Danube* (1891), *Capillary Crime and Other Stories* (1892) and *Expedition to the Philippines* (1899).

**MILLET, JEAN FRANÇOIS** (c. 1642–1679), commonly called Francisque, was born at Antwerp about 1642. He is generally classed among the painters of Flanders because of the accident of his birth, but his father was a Frenchman, who, while on service with the prince of Condé in Antwerp, apprenticed his son to a painter named Laurent. With Laurent Francisque left Antwerp for Paris, and there settled in 1660 after marrying his master's daughter. He was received a member of the Academy of Painting at Paris in 1673, and after gaining consideration as an imitator of the Poussins he died in 1679, bequeathing his art and some of his talents to one of his sons.

Francisque's paintings of Italian and Arcadian scenery were graceful and effective, although as he had not traveled his impressions of them were gained at secondhand. Twelve of his most important landscapes in the Tuileries were destroyed by fire; and though many of his pieces may still be found catalogued, a great number remain unknown and unacknowledged.

**MILLET, JEAN FRANÇOIS** (1814–1875), the French peasant who became a celebrated Barbizon painter and etcher, was born at Gruchy, near Gréville (La Manche) on Oct. 4, 1814. He spent his youth working on the land, but by the age of 19 he was

EWING GALLOWAY

"THE GLEANERS" BY JEAN FRANÇOIS MILLET. IN THE LOUVRE, PARIS

studying under Mouchel (real name Bon Dumoucel), a former pupil of J. L. David. These studies were interrupted by the death of his father in 1835, but in the spring of 1836 Millet was again at Cherbourg, studying now with J. C. Langlois (a pupil of A. J. Gros), who at the end of the year persuaded the authorities to finance Millet's further studies. In Jan. 1837, Millet arrived in Paris with an allowance of 1,000 francs and eventually enrolled in the studio of Paul Delaroche, where he seems to have remained until 1839. It was here that Millet came into contact with P. de Marolle, who introduced him to the works of La Fontaine and J. B. L. Gresset, which provided subjects for "Le Lutrin Vivant" and "Vert-Vert."

After the rejection of one of his entries for the Salon of 1840, Millet returned to Cherbourg where he remained during most of 1841. Here he painted a number of portraits including those of M. and Mme. Feuardent and that of his first wife, Pauline Virginie, whom he married in Nov. 1841. Rejected at the Salon of 1842, Millet achieved his first success in 1844 with "The Milkmaid" and a large pastel, "The Riding Lesson." The pastel shows the type of work which was to occupy a large part of his production during the 1840s, and which has a sensual character somewhat reminiscent of N. V. Diaz, J. H. Fragonard and Correggio. The "Offering to Pan" (1845) and "Oedipus Taken From the Tree" (1847) are important examples of this type. With the death of his first wife in April 1844, Millet again returned to Cherbourg, remaining in that area until 1845. Among portraits painted at this time are the "Antoinette Hébert" and the "Officer of Marine." The technical variety of his work up to this time indicates the range of Millet's interests and enthusiasms—Italian primitives, Michelangelo, Poussin, Ribera, Titian and Rembrandt. From 1845 dates Millet's union with Catherine Lemaire, a union which was legalized in 1853.

The peasant subjects, which from the early 1850s were to be Millet's principal concern, made their first important appearance at the Salon of 1848 with "The Winnower." The first version, later destroyed by fire, was purchased by A. A. Ledru-Rollin, who also secured for Millet a state commission for which the artist painted "The Haymakers at Rest" (1848–49, Louvre). After the Salon of 1849 ("The Seated Peasant Girl," Boston), Millet left Paris for Barbizon, a small hamlet in the forest of Fontainebleau. Barbizon was to become Millet's home for the remainder of his life; it was there that he died on Jan. 20, 1875. The Salon of 1850 included "The Sower" and "The Binders" and it was these paintings which first roused hostile critics to accuse Millet of being a socialist. This charge Millet refuted, but in a letter of Feb. 1851, he admits, "at the risk of appearing even more socialist, that it is the human, the frankly human side which moves me most in art." The same letter indicates a wish to have done with the "Nudes and Mythologies" for which he had acquired a reputation, but during the course of 1851 such works, if not produced, were still being offered for sale by Millet's friend and biographer, A. Sensier. The Salon of 1853 included "The Reapers" (now at Boston) which is probably identical with a "Ruth and Boaz," mentioned by Millet in a letter of 1851. This doubt concerning the real subject of the work may be indicative of Millet's idealistic attitude toward his subjects and his desire "to make the trivial serve to express the sublime." Major works of the following years, conceived in much the same spirit, are "A Peasant Grafting a Tree" (1855), "The Gleaners" (1857), "The Angelus" and "Death and the Woodcutter" (1858–59), "Sheep Shearing" (1860), "Sheepfold by Moonlight" (1861), "The Potato Planters" (1862) and "The Man With a Hoe" (1863). This last painting again raised the accusation that Millet was a socialist, and letters of the period defending Millet's position underline the fundamentally classical nature of his approach to painting.

In 1860, Millet entered into contract with two picture dealers, Arthur Stevens and Ennemond Blanc. The agreement, which was to provide him with a fixed income for three years, did not work out very satisfactorily. It did, however, ensure a regular showing of those works which had come into the possession of Blanc. By the middle of the 1860s, Millet's work was beginning to be in demand; official recognition came in 1868, after nine important paintings had been shown at the Exposition of the previous year. Important collections of Millet's pictures are to be found in the Museum of Fine Arts, Boston (68 pastels and paintings) and in the Louvre (23 pictures).

**MILLET** is the name applied to various small-seeded grasses that were probably first cultivated in Asia or Africa. All are annual, warm-season plants with small edible seeds. Important millets are pearl or cattail millet, called bajri in India (*Pennisetum glaucum*), foxtail millet (*Setaria* [*Chaetochla*] *italica*), proso, common or broomcorn millet (*Panicum miliaceum*), and finger, or coracan millet, also called ragi, (*Eleusine coracana*). Others include Japanese millet (*Echinochloa crus-galli* var. *frumentacea*), koda or ditch millet (*Paspalum scrobiculatum*), browntop (*Panicum ramosum*) and little millet (*Panicum miliare*). The finger, koda and little millets are not grown in North America. Sorghum (*q.v.*) is erroneously called millet.

J. HORACE MCFARLAND CO.

FOXTAIL MILLET (SETARIA ITALICA)

With the exception of pearl millet, these grasses range from one to four feet in height. The heads of pearl and foxtail millets are rather dense cylindrical spikes; those of finger and koda are racemes; and other millets bear panicles. Flowers are largely cross-pollinated. All seeds except pearl millet remain enclosed in hulls after threshing. Hulled seeds are mostly creamy white.

Pearl millet, a popular food crop in India and Africa, is well suited to soils of low fertility and limited moisture. Its stalks are five to ten feet tall and up to one inch or more in thickness. It provides abundant pasture and hay in the southeast U.S.

Proso, grown chiefly in Soviet Russia, Manchuria and China, has hairy stems and compact to loose panicles. The hulls on the seeds are red, light to very dark brown, gray, greenish-gray, yellow or white. The leading U.S. varieties are Yellow Manitoba, Turghai and Early Fortune. Proso ripens 60 to 80 days after sowing. The grain is used in birdseed and chick feed mixtures and as livestock feed in the United States, and as food in Asia and eastern Europe.

Foxtail varieties, including German or Golden, Common, Hungarian, Siberian, White Wonder and Kursk, have yellow, orange, green or gray hulls. Foxtail millets are grown for hay in North America and western Europe, but the small pointed seeds are important foods in China and other Asiatic countries.

Finger millet is an important food grain in southern Asia and parts of Africa. Japanese millet is grown chiefly for hay in Japan, the United States and some other countries. The little millet is grown for food chiefly in India. Browntop is grown in the southeastern United States for hay, pasture or feed for game birds.

Millets are sown in drills or cultivated rows in late spring or early summer after the weather is warm. The grain is harvested by the same methods used for wheat, barley or rice. Hulled millet grains, either whole or cracked, are cooked into porridge called *kasha* in Russia and Poland. Some grain is ground and made into unleavened breads. The composition of millet grain is similar to that of wheat, maize (corn) or rice.

About 26,000,000 tons of millet are produced annually, chiefly in China, India, Manchuria, U.S.S.R., countries of western Africa and Korea. In these countries the millets are used chiefly as food grains, but in western Europe and the United States millets are grown mostly for hay and pasture.

**MILL HILL FATHERS** (Societas Missionariorum S. Josephi de Mill Hill), a Roman Catholic society of common life founded by Herbert Vaughan at Mill Hill, London, in 1866. The priests, all British or Dutch, serving as missionaries chiefly in Africa and southeast Asia, numbered about 1,000 in the 1960s. *See* Orders and Congregations, Religious.

**MILLIKAN, ROBERT ANDREWS** (1868–1953), U.S. physicist, recipient of the 1923 Nobel prize in physics for his study of the elementary electrical charge and the photoelectric effect, was born at Morrison, Ill., on March 22, 1868. He graduated from Oberlin college (1891) and obtained his doctorate at Columbia university in 1895; later he was in residence at the universities of Berlin and Göttingen. In 1896 he was appointed to an assistantship in physics at The University of Chicago, where he became a full professor in 1910.

Millikan's earliest outstanding investigation was an accurate determination of the charge $\epsilon$ carried by an electron, followed by evidence that this charge was not merely a statistical mean but a definite constant. In this investigation he improved upon the method of the falling cloud (already employed, in several forms, at the Cavendish laboratory at Cambridge) by substituting for the indefinite cloud a single falling drop whose motion in the gravitational field could be easily measured and whose motion in the electrical field could be controlled. For this work Millikan was awarded the Comstock prize by the National Academy of Sciences in 1913; and in 1915 he was elected to membership in the academy. During the year 1916 he took up with the same skill the experimental verification of Einstein's well-known photoelectric equation $\frac{1}{2}mv^2 = Ve = h\nu - p$, and the evaluation of Planck's constant $h$. The result was a thorough confirmation of Einstein's equation and a value of $6.57 \times 10^{-27}$ for Planck's constant. (*See* Electron; Photoelectricity.)

In 1921 he resigned his chair at The University of Chicago to accept the directorship of the Norman Bridge Laboratory of Physics of the California Institute of Technology, at Pasadena, and became chairman of the executive council of the institute, a post he held with marked success until his retirement in 1945. He represented the United States for ten years (1922–32) on the League of Nations committee for intellectual co-operation and served as chairman of the board of directors of the Huntington Library and Art gallery, San Marino, Calif.

Millikan's research at the California Institute of Technology considered the cosmic rays (*q.v.*) ranging from the stratosphere to the bottoms of deep melted-snow lakes.

Following many honours—degrees, prizes, medals—that came to him during half a century of professional life, he died Dec. 19, 1953, in San Marino, Calif.

Millikan's publications include *The Electron*, 2nd ed. (1924, abridged ed. by J. W. M. Du Mond, 1963), *A First Course in Physics for Colleges* (with H. G. Gale and C. W. Edwards; 1925), *Evolution in Science and Religion* (1927), *Time, Matter, and Values* (1932), *Cosmic Rays* (1939), *Autobiography* (1950). *See* also references under "Millikan, Robert Andrews" in the Index.

**MILLIN, SARAH GERTRUDE** (née Liebson) (1889– ), South African writer, whose most outstanding novels, concerned with the problems of South African life, are remarkable for impartiality, vividness and clarity of style. Born of Jewish parentage in Lithuania, she was taken to South Africa as a baby. Her childhood on the diamond fields at Kimberley and on the river diggings at Barkly West, among the white, Coloured and black community, provided the background for much of her writing. In 1912 she married Philip Millin, who became one of South Africa's most distinguished supreme court judges, and thereafter her home was in Johannesburg.

Her first novel, *The Dark River* (1920), was set around Barkly West. Others followed, but it was *God's Stepchildren* (1924), dealing with the half-caste Coloured community, that made her famous. With *Mary Glenn* (1925), a study of a mother's reaction to her child's disappearance, she became recognized as one of the leading modern novelists in the English language, with her nervous, sharp, vivid, often almost staccato, style. *The South Africans* (1926; revised as *The People of South Africa*, 1950), a fair and realistic account of the mixed races and cultures of her country, was a venture in a new direction. Her biography of Cecil Rhodes (1933) was a work of great power, though criticized by those who knew him. For her life of Gen. J. C. Smuts (1936) she had access to private papers, but it suffered from appearing before his dramatic closing years. In some novels she used events in South African history; *e.g.*, *The Coming of the Lord* (1928), about a black "prophet" in the eastern Cape; and *King of the Bastards* (1950), on the life of the white chieftain Coenraad Buys. *Men on a Voyage* (1930) is a collection of essays, and a series of impressive war diaries (1944–48) was inspired by the sufferings of mankind in general and of the Jewish people in particular. She wrote two autobiographical books, *The Night Is Long* (1941) and *The Measure of My Days* (1955).

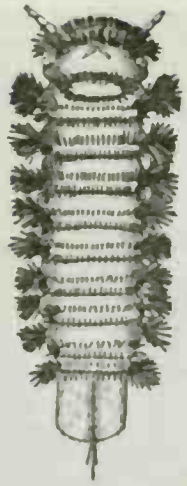
**MILLING:** *see* Flour.

**MILLING MACHINE:** *see* Machine Tools.

**MILLIPEDE,** a common name for a group of many-legged, air-breathing arthropods having cylindrical segmented bodies and now recognized as a distinct class, Diplopoda. They were formerly placed as an order or subclass under Myriapoda (*q.v.*) until accumulated evidence made it impossible to regard the latter as a homogeneous or wholly natural assemblage. Millipedes, many of which are brightly coloured, are worldwide in distribution, their numbers, species and sizes being greatest in the tropics and decreasing notably toward the polar regions. Geologically they were among the most ancient of land animals. Millipedes, or forms closely related to them, occurred in the swamps of Carboniferous times, some of them one foot in length and probably amphibious. Fossils of other forms have been found in rocks of Silurian age.

## STRUCTURE AND FUNCTION

**Body Form.**—The head segment is as distinct as it is in insects, whereas the remaining segments follow each other in rather monotonous succession, to form a continuous trunk or body. The name Diplopoda is derived from the fact that most of the apparent segments of the body bear two pairs of legs resulting from a complete or partial fusing of the primary segments in couples, each couple having a single dorsal plate (tergite) while retaining two sterna. One or two of the posterior (caudal) segments and usually four of the most anterior segments remain single. Of these four, three bear only a single pair of legs, while the other—usually the



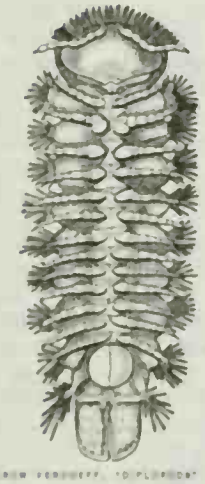


FIG 1.—POLYXENUS LAGURUS DORSAL AND VENTRAL VIEWS

first—remains legless. In some forms the number of segments in the body is invariable. Thus in the large order Polydesmida hundreds of species invariably have 20 segments, though in some this number holds only for the female, the male having 19. In millipedes consisting of more than 32 segments the number is variable not only from group to group and from species to species but also to a certain extent within a species itself. The number of segments approaches 200. Millipedes vary in length from about 2 mm. to almost 300 mm.; the width ranges up to 50 mm., as in some of the family Sphaerotheridae.

The often cylindrical body of millipedes may be modified to hemicylindrical or may even appear more flattened through a lateral extension of the segments. Millipedes, when disturbed, generally curve the body into a spiral or, in the broader forms, into a ball. Although in rare cases (*e.g.*, *Polyxenus*) the body is soft, in most species it is covered by a crustaceous shell or armour, the skin (integument) consisting of a strong base of chitin stiffened by a rich deposit of lime salts. Millipedes, like many other arthropods, grow between molts; as each old integument is discarded the new soft one is exposed. Since the animal is particularly vulnerable at this time it usually retires to a concealed nest or retreat.

**Stink Glands.**—With the exception of the crustaceous integument, stink glands comprise the only protection of most millipedes. These glands discharge their product through pores located along the sides of the body. The secretion is sometimes exuded as a gas, but more frequently as a liquid which may be colourless or may range from white to yellow, brown or red. In composition it varies considerably from group to group but in many common forms has been found to contain hydrocyanic acid, iodine and quinone. It has a pungent odour and is toxic enough to kill certain insects. Injury to the human skin may result from accidental contact, as when the animals find their way into bedding or clothing. The secretion is extruded when the millipede is disturbed, especially when it is in the process of rolling up, at which time the secretion may be squirted a considerable distance.

**Sense Organs.**—The head of millipedes bears a pair of relatively short antennae, each composed of seven or eight sections of which the terminal one bears four or more sensory cones. The eyes in most forms are composed of one or many simple ocelli on each side but they may be absent, as in the large order Polydesmida. A pair of mandibles are present. These are typically fitted for biting or chewing and have a terminal lobe with combs used in scraping off the soft portion of food tissues. Only one pair of maxillae are developed, the first pair in adults being absent or represented merely by rudiments. The second pair of maxillae form a large, complicated plate termed the gnathochilarium, which varies much in detail in different groups. This plate is generally accepted as homologous with the labium of insects, but is more highly evolved. Poison jaws, characteristic of centipedes, are never present.

FIG 2.—GLOMERIDESMUS MEXICANUS

**Respiratory and Circulatory Systems.**—Millipedes breathe by means of tracheae, one pair on each segment bearing one pair of legs, and two pairs on each fused double segment. The opening (stigma) of each trachea lies in the corresponding sternum. Each stigma opens into a pocket from which branches proceed. Each

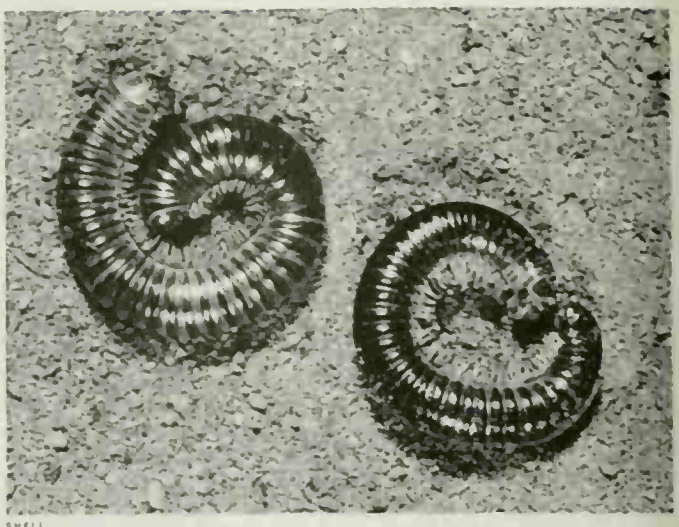

FIG. 3.—BLACK MILLIPEDES (TACHYPODOIULUS NIGER)

tracheal system is independent and shows no fusion (anastomosis), in this respect contrasting with the systems of insects and centipedes. The alimentary canal is a short, almost straight tube, which at most shows only an S-shaped flexure posteriorly. The canal has three divisions: a narrow foregut (esophagus), a thicker midgut and a narrow hindgut into which open two or four Malpighian tubules. Salivary glands open into the mouth. The heart is a tube running lengthwise above the alimentary canal. The lateral openings into the heart (ostia) occur in double pairs in each double segment. The nervous system consists of a ventral nerve cord, which has ganglionic swellings in each segment—two pairs of them in each double segment. In the head the nerve cord is joined by a ring with the small brain lying above the esophagus. The paired reproductive organs lie between the intestine and the ventral nerve cord, their ducts opening through the coxae of either the second legs or those directly behind.

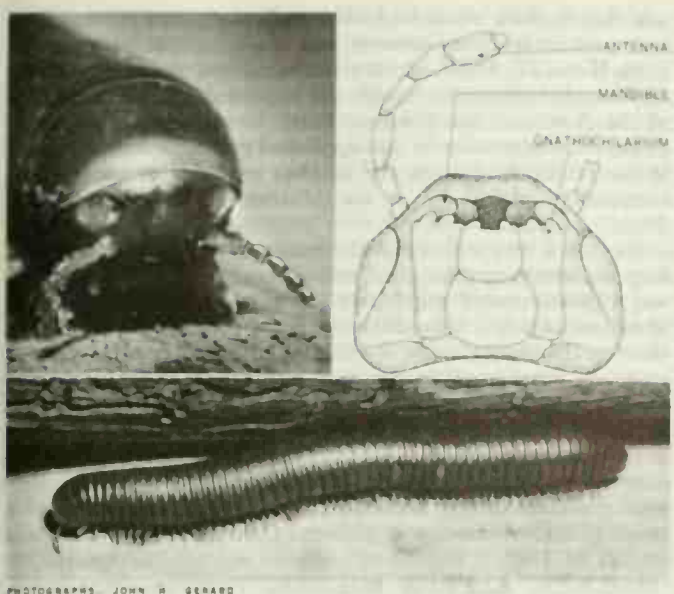
## NATURAL HISTORY AND REPRODUCTION

**Habitat.**—In contrast with the centipedes, which are carnivorous, the millipedes are inoffensive creatures living primarily upon decaying vegetable—or, rarely, animal—matter. A few forms feed upon the rootlets or other delicate tissues of living plants, sometimes damaging vegetable crops. They live in damp localities under decaying logs and leaves, and in dry seasons may be found at considerable depths in the soil where they have followed the retreating moisture. In comparison with other ground-dwelling animals such as beetles and spiders, millipedes occur only sparsely in a given area. Occasionally, however, they appear suddenly and in great numbers—for some reason not fully understood—often migrating in swarms, entering houses and becoming a nuisance (because of their crushed bodies) on roads and railroad tracks. Generally, millipedes are subject to factors of isolation; as a result they are among the most useful animals in studies of geographical distribution.

**Life Cycle.**—The eggs of millipedes are most commonly laid below the surface of the ground in clumps of from 25 to 50, the clumps being enclosed in an earthy capsule or sometimes, as in *Polydesmus*, in a capsule made of pellets of excrement. The fe-



PHOTOGRAPHS, JOHN H. GERARD

FIG. 5.—(TOP LEFT) CLOSE-UP OF HEAD OF NARCEUS SHOWING SIMPLE EYES PRESENT IN SMALL AGGREGATES. (TOP RIGHT) HEAD OF JULUS FROM BELOW. (BOTTOM) NARCEUS MILLIPEDE AT APPROXIMATELY ACTUAL SIZE

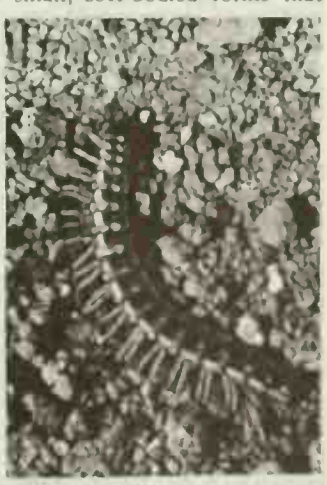
male often remains with the eggs until the young hatch out. In the course of development the embryo usually leaves the egg in a quiescent, pupoidal form. Soon emerges a larva resembling a wingless insect with three pairs of legs, behind which lie four footless segments. Following this first stage new segments are added in groups of one, two, three or more double segments. The development is thus anamorphic. The attainment of each new stage is preceded by a pause or rest period. The animal occupies a retreat or nest while undergoing the molting process as mentioned earlier. More rarely the first free larva possesses four (*e.g.*, Polyzonium) or even more pairs of legs. The new segments are invariably produced between the last leg-bearing segment and the final, or anal, segment.

Millipedes that breed and lay their eggs in the autumn commonly die out by early winter, the males disappearing first. In these types a new generation emerges from the eggs in early spring, the life cycle being completed within a year's time. Other millipedes may live two years and some are estimated to live as long as seven years.

## CLASSIFICATION

The class Diplopoda embraces two subclasses: the Pselaphognatha and the Chilognatha.

I. The Pselaphognatha include small, soft-bodied forms that bear bristles (setae) of several kinds arranged in rows and bundles (fascicles). Copulatory organs (gonopods) are lacking and the gnathochilarium is abortive or poorly developed (*e.g.*, Polyxenidae).



SHELL

FIG. 6.—FLAT-BACKED MILLIPEDE (POLYDESMUS ANGUSTUS)

II. The Chilognatha include the great majority of millipedes. In these the integument forms a hard shell which bears setae only singly, never grouped in fascicles, and the gonopods are always well developed. The major subdivisions of this subclass may be listed as follows:

1. Superorder Pentazonia (Opisthandria): the gonopods are at the tail end of the body, being modified from the last two pairs of legs; tracheae two-branched (*e.g.*, orders Glomerida and Glomeridesmida).

2. Superorder Colobognatha: first legs of seventh segment of males not modified; eight pairs of legs in front of the gonopods; head small, mandibles usually much reduced; labrum without teeth; tracheae unbranched (*e.g.*, orders Platydesmida and Polyzoniida).

3. Superorder Helminthomorpha: first legs of seventh segment of male always modified; seven pairs of legs in front of the gonopods; head not reduced; mouthparts of normal size; labrum usually with three teeth; tracheae unbranched (*e.g.*, orders Polydesmida, Chordeumida, Julida, Spirobolida, Cambalida and Spirostreptida).

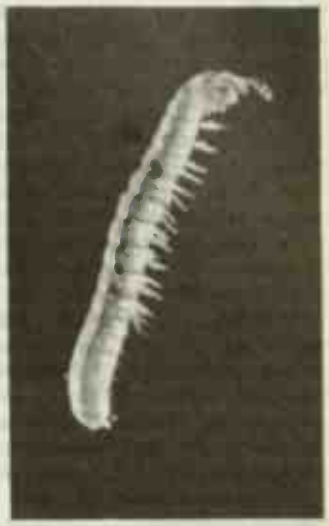


FIG. 7.—YOUNG SPOTTED SNAKE MILLIPEDE (BLANIULUS GUTTULATUS)

In contrast with the Pentazonia (Opisthandria), the second and third superorders are often placed as the Proterandria, because of their agreement in having the copulatory organs on the seventh segment and in not having the tracheae branched.

BIBLIOGRAPHY.—The best accounts of the Diplopoda as a whole are in German and French. To be mentioned specially are the following: Carl Graf Attems' treatment in Kukenthal and Krumbach's *Handbuch der Zoologie*, vol. iv (1926); Karl W. Verhoeff in Bronn's *Klassen und Ordnungen des Tierreichs*, vol. v (1910–1914, 1926); H. W. Brolemann, "Myriapodes Diplopodes," in *Faune de France*, 29 (1936 *et seq.*). Many excellent papers and monographs on particular regions and groups have appeared by these and other authors. For the diplopods of North America a complete bibliography is given in R. V. Chamberlin and R. L. Hoffman, "Checklist of the Millipedes of North America," *Bull. U.S. Nat. Mus.*, 212 (1958). (R. V. C.)

**MILLS, ROBERT** (1781–1855), the first strictly professional architect of U.S. birth, was born on Aug. 12, 1781, in Charleston, S.C. Mills generally followed the principle enunciated by Thomas Jefferson, that classical architectural forms best befitted a reincarnation of ancient republics, *i.e.*, the new United States, but he used those forms with originality, both in plan (*e.g.*, his auditorium type of evangelical church) and structure (*e.g.*, his ideas about fireproofing and acoustics). Mills's more than 50 major works included colleges, prisons, hospitals, houses, canals, bridges and breakwaters. His most famous buildings, however, were public—the Treasury (1836–42) and Patent office (1839) in Washington, D.C., the wings of Independence hall in Philadelphia (1807) and, best known of all, the monuments to George Washington in Baltimore (1814) and Washington, D.C. (designed 1836, completed 1884).

Mills died on March 3, 1855, at Washington, D.C.

*See* H. M. Pierce Gallagher, *Robert Mills* (1935); T. F. Hamlin, *Greek Revival Architecture in America* (1944). (AN. G.)

**MILNE, ALAN ALEXANDER** (1882–1956), English humorist, poet of childhood and minor playwright, best-known for his children's stories about Christopher Robin and his animals—"Pooh," "Piglet," "Kanga," "Roo" and "Eeyore"—was born on Jan. 18, 1882, in London, and educated at Westminster school and Trinity college, Cambridge. In 1906 he joined the staff of *Punch*, writing humorous verse and whimsical essays in a style that has become dated. He wrote his first published play (*Wurzel-Flummery*) while serving with the Royal Warwickshires in 1917, and achieved considerable success with light comedies, of which the best are *Mr. Pim Passes By* (1919), *The Dover Road* (1922) and *Michael and Mary* (1929). He also attempted the novel, but his detective story, *The Red House Mystery* (1921), is the only memorable one.

Although his fifth play was the brilliant extravaganza for children, *Make-Believe* (1918), he stumbled into his true literary kingdom by chance with some verses written to order, about his son, Christopher Robin. These grew into the collections *When We*

*Were Very Young* (1924) and *Now We Are Six* (1927), some of the best light verse for children ever written. But they were surpassed by two sets of stories about Christopher Robin's toy animals, *Winnie-the-Pooh* (1926) and *The House at Pooh Corner* (1928), the most-quoted children's classics since Lewis Carroll's *Alice's Adventures in Wonderland* (1865). *Toad of Toad Hall* (1929), a play based on Kenneth Grahame's *The Wind in the Willows*, retains its popularity but falls far short of its original. Milne will be remembered for his nursery verse, and as the creator of "Pooh Bear," whose sayings and doings have become a part of the language. He died at Hartfield, Sussex, on Jan. 31, 1956.

*See* his autobiography, *It's Too Late Now* (1939). (R. L. Gr.)

**MILNE, EDWARD ARTHUR** (1896–1950), English mathematician, astrophysicist and cosmologist, best known in his later years for his original researches in relativity and cosmology, was born at Hull on Feb. 14, 1896. He was educated at Hymers college, Hull, and at Trinity college, Cambridge, where he was elected to a prize fellowship in 1919. In 1920, he became assistant director of the Solar Physics observatory. Four years later, he was elected professor of applied mathematics at Manchester university.

In 1928 Milne was appointed first Rouse Ball professor of mathematics at Oxford. He became a fellow of the Royal society at the age of 30, and was awarded a Royal medal in 1941. He died suddenly in Dublin on Sept. 21, 1950.

Milne first became internationally known for his pioneer work on the theory of stellar atmospheres. He showed, in collaboration with R. H. Fowler, that the pressures of the levels of stellar atmospheres where absorption lines are formed are considerably lower than previously imagined. He also found that atoms can be ejected from the sun at about 1,000 mi. per second. In 1929, Milne turned his attention to problems of stellar constitution and became an acute critic of A. S. Eddington's hypothesis that the interior of a star obeys the perfect gas law throughout. He did much work on the highly dense white dwarf stars which afterward stimulated S. Chandrasekhar to develop the now generally accepted theory.

Milne's theory of the expanding universe was easier to visualize physically than that based on Einstein's theory of general relativity. In place of expanding curved space, Milne considered a cloud of particles expanding into a vacuum in flat space. In studying such a system, he was led to develop a new form of relativity, called kinematic relativity, based on a deep analysis of time measurement. Milne's works include *Thermodynamics of the Stars* (1930); *The White Dwarf Stars* (1932); *Relativity, Gravitation and World-Structure* (1935); *Kinematic Relativity* (1948). (G. J. Ww.)

**MILNE, JOHN** (1850–1913), British seismologist and mining engineer who was largely responsible for the establishment of seismological observation stations throughout the world, was born at Liverpool on Dec. 30, 1850, and educated at King's college, London, and the Royal School of Mines. He worked as a mining engineer in Newfoundland and Labrador, and in 1874 went as geologist with C. T. Beke's expedition to Egypt and northwestern Arabia. In 1875 he was appointed professor of geology and mining in the Imperial Engineering college at Tokyo, where he remained for 20 years. Milne was recognized as a leading authority on seismology. He traveled widely in the east, and about 1880 established the seismic survey of Japan, with 968 stations. He invented various forms of the seismograph (*q.v.*). In 1894 he returned to England and established a private observation station near Newport, Isle of Wight. It was as secretary of the seismological committee of the British association that he organized a world-wide network of observation stations. He died at his home on the Isle of Wight on July 30, 1913.

He published two standard works, *Earthquakes* (1883) and *Seismology* (1898), besides many books on mining and crystallography and papers in scientific journals.

**MILNE-EDWARDS, HENRI** (1800–1885), Belgian zoologist prominent in comparative anatomy, comparative physiology and general zoology, was born at Bruges on Oct. 23, 1800, the son of British parents settled in Belgium. He studied in Belgium and then in Paris where he took a medical diploma in 1823. He soon gave up medicine, however, and taught natural history at the *lycée* Henri IV, where in 1827 he introduced the theory of the division of physiological labour. In 1838 he was elected a member of the Académie des Sciences, Paris, in succession to Georges Cuvier. Subsequently he was appointed professor of entomology at the Jardin des Plantes and in 1844 professor of zoology and comparative physiology at the Muséum d'Histoire Naturelle, Paris.

He took a very active part in organizing courses in natural history and was a member of several government commissions. He was a prolific writer and keenly interested in the popularization of natural history. Milne-Edwards also made important contributions on the shore animals of France and Sicily, especially on the anatomy, physiology, classification and habits of Crustacea and Coelenterata. He was the author of various textbooks, the most important being *Leçons sur la physiologie et l'anatomie comparée de l'homme et des animaux*, 14 vol. (1857–81). He was one of the most outstanding of those zoologists who refused to accept Darwin's evolution theory, and explained zoological distribution as a result of special creation in different centres. He died in Paris on July 28, 1885. (Ed. He.)

**MILNER, ALFRED MILNER,** Viscount (1854–1925), imperial administrator who played a decisive role in the history of South Africa, was born at Giessen, Hesse-Darmstadt, on March 23, 1854, of English and German descent; his father, Charles Milner, was a medical doctor and a teacher of English literature. Milner's childhood was spent alternately in Germany and in England; he entered the Tübingen *gymnasium* in 1866 and after his mother's death in 1869 moved to King's college, London. He won a scholarship in 1872 to Balliol college, Oxford, where he had a brilliant career. He was president of the Oxford union, took first classes in classical moderations and Greats, won the Hertford, Craven, Eldon and Derby scholarships, and in 1876 became a fellow of New college. At Oxford he also became an ardent advocate of imperialism and social reform.

Milner left Oxford for London in 1879 and two years later was called to the bar of the Inner Temple. As legal work was scarce he turned to journalism and worked for the *Pall Mall Gazette* under John (later Viscount) Morley and W. T. Stead. He stood for Harrow as a Liberal candidate in the general election of 1885, but was defeated. His public career started in 1887, when he was appointed official private secretary to G. J. (later Viscount) Goschen, chancellor of the exchequer. He served with distinction under Sir Evelyn Baring (afterward Lord Cromer) in Egypt from 1889 to 1892 and wrote *England in Egypt* (1892), an analysis of the problems of Egyptian administration and a vindication of British intervention. He then became chairman of the board of inland revenue, where he was responsible for formulating Sir William Harcourt's celebrated death duties. His services were rewarded with a knighthood in 1895.

**High Commissioner in South Africa.**—Joseph Chamberlain, colonial secretary in Lord Salisbury's cabinet, selected Milner in 1897 as governor of Cape colony and British high commissioner in South Africa, the cardinal imperial appointment of the time. Relations between Britain and the South African republic were already strained. Britain regarded the republic as falling within its exclusive sphere of influence and as being subject to its suzerainty. The republican government of Pres. Paul Kruger denied that British suzerainty existed under the London convention of 1884 and was striving to preserve Boer supremacy over the republic in the face of the challenge presented by the influx of many British and other *uitlanders* to the Witwatersrand gold fields (*see* Transvaal: *History*). Boer suspicions of Britain had recently been intensified by the Jameson raid which was a plot to coerce the republic back into the empire.

During his first ten months in South Africa Milner held his hand, touring Cape colony and picking up the threads of its politics; but Kruger's alliance with the Orange Free State, his military preparations and his re-election as president for a fourth term in Feb. 1898 led Milner to consider that Britain should intervene to assert its paramountcy. First, he hoped to secure a government

in Cape colony that would support his plans. Accordingly, in a speech at Graaff Reinet in March 1898 he criticized the Cape Afrikaners for espousing the cause of the South African republic and made it clear that his sympathies lay with the imperialistic Progressive party. Nevertheless the Afrikaner Bond and its allies obtained a narrow majority in a general election, and in Oct. 1898 W. P. Schreiner formed a ministry which included Bondsmen and depended on Bond support.

At the end of 1898 Milner went to England for consultation with the colonial secretary and after his return to South Africa in Feb. 1899 he and Chamberlain put persistent pressure upon Kruger. In March, Milner ensured that a Cape ministerial proposal for a conference of South African states and colonies should come to nothing. In response to Chamberlain's request for a statement for publication, he dispatched a vigorous telegram on May 4 describing the *uitlanders* as being "in the position of *helots*" and asserting that the case for British intervention was "overwhelming." Between May 31 and June 5, in conference with Kruger at Bloemfontein, he demanded full citizenship rights for *uitlanders* after five years' residence, and abruptly terminated the discussions when Kruger refused to grant so much. When the republican *volksraad* adopted a law making considerable concessions in July, Milner criticized it as inadequate. And when J. C. Smuts, the republican state attorney, offered in Aug. 1899 more than Milner had demanded at Bloemfontein, the latter advised Chamberlain to reject the offer on account of the conditions attached to it. By then, indeed, Milner had determined that British supremacy should be asserted by force and he was content when war broke out on Oct. 11, 1899, following an ultimatum from the two republics. (*See* SOUTH AFRICAN WAR.)

During the war Milner was created baron (1901) and viscount (1902). While retaining the high commissionership, he handed over the governorship of Cape colony to Sir Walter Hely-Hutchinson in 1901 and became administrator (later governor) of the former republics; he was also primarily responsible for the post-war settlement. His plans were far-reaching. The Witwatersrand gold-mining industry was to provide a surplus to stimulate the rapid expansion of the entire South African economy. It was also to attract a large number of British immigrants, while British settlers were to be assisted to establish themselves on the land, so that a permanent British majority would be created in the white South African population. The Boers were to be weaned from their cultural and racial isolation not only by the effects of economic change and British immigration but also by a vigorous educational program, with all teaching in the English language. The Transvaal and the Orange River colony were to be ruled as crown colonies for an indefinite period and Cape colony was to forfeit its constitution and be reduced to the same status. Only when his economic, immigration and educational policies had borne fruit would it be safe and desirable to create a federal dominion of British South Africa, which would have full internal self-government and, Milner hoped, be so loyal that it would support his broader project of imperial federation, under which an imperial council or parliament would be formed, with powers over the defense and the trade of the empire. To assist him in these tasks he recruited a group of bright young men from Oxford, known as "Milner's kindergarten," including Patrick Duncan, Lionel Curtis, Robert Brand and Philip Kerr, to occupy the key posts in the Transvaal administration.

**The Period of Settlement.**—Milner and Lord Kitchener represented Britain in the negotiations that led to the signing of the treaty of Vereeniging on May 31, 1902. It was Milner who made sure that the treaty specified no date for the introduction of self-government in the Transvaal and the Orange River colony and included no promise that the Dutch language would rank equally with English. In return he yielded completely to the colour consciousness of the Boers, in the clause that made no concessions to the African and Asian inhabitants of the new colonies and provided that no "native" would be given the vote before the introduction of self-government. At about the same time, however, he failed to persuade Chamberlain to suspend the constitution of Cape colony.

For the next two years Milner's administration was largely concerned with re-establishing the Boers on the land, and this work was efficiently and generously performed. But in other respects his policy was not a success. Although his schools gave young Afrikaners unprecedented educational opportunities, his insistence upon the use of English provoked organized Afrikaner opposition. The gold-mining industry was expanding quite rapidly and Milner persuaded the colonial secretary to alleviate the shortage of unskilled labour by allowing the importation of Chinese on short-term contracts, terminating in compulsory repatriation. This decision evoked widespread opposition in South Africa and reports of ill-treatment of the Chinese labourers gave Milner's opponents in England a powerful weapon. There was also a considerable emigration of British people from Cape colony and Natal during the postwar depression, while the scale of British immigration to the Witwatersrand was not so great as Milner had hoped; his land settlement schemes produced only about 1,000 settlers, so that Afrikaners continued to form a substantial majority of the white South African population.

In 1904, in an attempt to stave off more radical changes, Milner persuaded Alfred Lyttelton, Chamberlain's successor, to sponsor a constitution that would have given the Transvaal representative, but not responsible government. But by then Milner was being opposed by some British South Africans as well as by most Afrikaners, and in Britain the reaction against him and against the Unionist government was becoming powerful. He resigned from his South African appointments in April 1905 and returned to England, hoping that his successor, Lord Selborne, might be able to inaugurate the Lyttelton constitution and save something of his work. However, the Lyttelton constitution was stillborn. Sir Henry Campbell-Bannerman's Liberal cabinet took office in Dec. 1905, was confirmed in power at the polls in Jan. 1906 and proceeded, to Milner's acute dismay, to grant full self-government to the Transvaal and the Orange River colony, with electoral provisions that enabled predominantly Afrikaner governments to obtain control of both colonies in 1907.

**Last Years.**—For several years after his return from South Africa Milner remained out of public employment and out of sympathy with the British government. In the house of lords he vehemently opposed the "people's budget" of 1909, the Parliament act of 1911 and Irish Home Rule. Early in World War I, however, he presided over committees on food production and coal production and in 1916 he became a member of Lloyd George's war cabinet, where his administrative gifts were used to full advantage. He also undertook missions to Rome and St. Petersburg (Leningrad), and in the military crisis of March 1918 he went to France and secured unity of command under Gen. Ferdinand Foch. Milner became secretary for war in April 1918 and then in December moved to the colonial office. As colonial secretary he attended the peace conference and signed the treaty of Versailles. Later he spent four months in Egypt and recommended that it should be given a qualified form of independence, but the cabinet rejected his advice and in Feb. 1921 he resigned. Three weeks later he married Violet, the widow of Lord Edward Gascoyne-Cecil. He died of sleeping sickness at Sturry court, near Canterbury, on May 13, 1925.

The most significant part of Milner's career was his South African high commissionership, which was the crest of the late-19th-century wave of British imperialism. To it he brought great administrative talents, a clear-cut idealism and an inflexible will. However, his attempt to destroy Afrikaner nationalism proved to be a boomerang, for Afrikaner nationalism came to thrive upon a tradition of "Milnerism" which, though exaggerated, was not entirely false. His constant appeal to British racial fervour misled British South Africans into nourishing unattainable aspirations. And his failure to raise the status of the non-white inhabitants of the Transvaal and the Orange River colony removed the strongest vindication that might have existed for the war that his diplomacy had done so much to bring about. *See also* SOUTH AFRICA, REPUBLIC OF: *History*.

**MILNER, JOHN** (1752–1826), English antiquary and Roman Catholic controversialist, had great influence in the campaign to obtain the parliamentary relief of Catholics from legal disabilities. Born in London on Oct. 14, 1752, and educated first at Sedgeley Park school, near Wolverhampton, and later at the English college at Douai, in France, Milner was ordained priest in 1777 and returned to pastoral work in England, chiefly at Winchester. His *The History, Civil and Ecclesiastical, and Survey of the Antiquities of Winchester*, two volumes (no date [1798–1801]), was very well received and achieved a third edition in 1839. Even more famous was his *The End of Religious Controversy*, published in 1818. In 1803 Milner became titular bishop of Castabala and vicar-apostolic of the Midland district. He died on April 19, 1826.

Milner's chief political success was to prevent parliament's granting relief to Catholics from the penal laws of an earlier age on terms unduly restrictive of papal power. In this he was unsuccessfully opposed by influential Catholic laymen and even bishops who were prepared to take oaths incompatible with Catholicism and to grant the English government a power of veto over the appointment of Catholic bishops. Milner's resistance was sustained in numerous published writings marred, however, by a too great asperity of style.

(E. McD.)

**MILNGAVIE** (locally pronounced "Milguy"), a small burgh of Dunbartonshire, Scot., 6 mi. N.N.W. of Glasgow. Pop. (1961) 8,894. Industries include light engineering and the making of paper, cardboard boxes, bedding, scientific instruments and spectacle frames; but the town is largely a residential quarter for Glasgow. Mugdock and Craigmaddie reservoirs store water from Loch Katrine. Bardowie castle is 1¼ mi. E.S.E. and Mugdock castle, 1¾ mi. N. of Milngavie, is an old stronghold of the Grahams; in Baldernock parish, about 2 mi. E., a megalith called the "Auld Wives' Lift" stands on a hill 400 ft. high.

**MILO** (Milon), of Crotona, Greek athlete, lived about the end of the 6th century B.C. He was six times crowned at the Olympic games and six times at the Pythian for wrestling, and was famous throughout the civilized world for his feats of strength—such as carrying an ox on his shoulders through the stadium at Olympia. In his native city he was much honoured, and he commanded the army which defeated the people of Sybaris in 511.

The traditional account of his death is often used to point a moral: he found a tree which some woodcutters had partially split with a wedge, and attempted to rend it asunder; but the wedge fell out, and the tree closed on his hand, imprisoning him till wolves came and devoured him. His name became proverbial for personal strength.

**MILO, TITUS ANNIUS** (d. 48 B.C.), Roman politician from Lanuvium, was the son of C. Papius Celsus, but was adopted by his mother's father, T. Annius Luscus. He supported Pompey, and organized bands of mercenaries and gladiators against P. Clodius (*q.v.*). Milo was tribune of the plebs in 57. He actively promoted the recall of Cicero from exile, in spite of Clodius. He tried to prosecute Clodius and prevent his election to the aedileship; in 56 Clodius attempted in turn to prosecute Milo. Milo was praetor in 55. In 53 Milo was candidate for the consulship and Clodius for the praetorship; strife continued until the two leaders met at Bovillae and Clodius was murdered (Jan. 52). Milo was impeached, his guilt was clear, and his enemies took every means of intimidating his supporters and his judges. Cicero was afraid to speak, and the extant speech *Pro Milone* is an expanded form of the unspoken defense. Milo went into exile at Massilia (Marseilles). He was the only man excepted from Caesar's general amnesty. He joined M. Caelius Rufus in 48 in his rising against Caesar, but was killed near Thurii. His wife was Fausta, daughter of the dictator Sulla.

**MILORADOVICH, MIKHAIL ANDREEVICH** (1771–1825), Russian army officer who distinguished himself in the French Revolutionary and Napoleonic Wars. Having had early experience under Gen. A. V. Suvorov in the wars against Turkey and against Poland, he won some reputation as a commander of advanced troops in Suvorov's campaign in 1799 in Italy and Switzerland. In 1805, having attained the rank of lieutenant general, he served under Gen. M. I. Kutuzov in the campaign that ended disastrously at Austerlitz. When war with the Turks broke out again, he commanded the army corps that took Bucharest in Dec. 1806 and won two victories on the Danube in 1807. In 1810 he was promoted to the rank of general of infantry. When the French invaded Russia in 1812 he commanded a corps at Borodino and subsequently a rear guard covering the Russian army's retreat toward Kaluga; and when the French began their retreat his corps was active in pursuit of them. In 1813, however, the Russians and their allies sustained some defeats in central Europe, and Miloradovich found himself again in command of a rear guard; but on the recovery of the allies he led a Russo-Prussian corps at the battle of Leipzig and in the campaign of 1814. He was appointed military governor of St. Petersburg in 1818 and remained in command until he was shot in the rising of the Dekabrists there on Dec. 26 (new style; 14, old style), 1825.

**MILOSH** (Milosh Obrenovich I; originally Milosh Teodorovich) (1780–1860), prince of Serbia from 1815 to 1839 and from 1858 to 1860, the founder of the Obrenovich dynasty. He was born at Srednja Dobrinja on March 18 (new style; 7, old style), 1780, the first child of a poor peasant, Teodor Mihailovich (d. 1802), by his wife Vishnya (d. 1819), who already had three children by her former husband Obren Martinovich. In early life a herdsman, Milosh worked at Brusnica for his half brother Milan (d. 1810). In 1807 he married Lyubitsa Vukomanovich (1788–1843), by whom he eventually had two daughters and two sons, Milan and Michael.

During the first Serbian rising (1804–13), Milosh distinguished himself and was appointed commander (1805). After his half brother's death, he changed his name from Teodorovich to Obrenovich. Being in opposition to Karageorge (*q.v.*), he was arrested in 1811 but immediately pardoned. After the Bucharest treaty of 1812, Karageorge took refuge in Austria, but Milosh remained behind and was appointed by the Turks to be *knez* (prince) of three central Serbian districts. He used his influence to pacify the country and protect the population. When Haji-Prodan's rebellion broke out (1814), Milosh helped the Turks to restore order; but when they started large-scale massacres he proclaimed to the assembled leaders outside Takovo church on Palm Sunday 1815: "Here am I; there you are: war to the Turk!" He routed the Turkish regulars at Palez (now Obrenovac), Ljubic and Dublje. The Turks, fearing Russian intervention, preferred to settle their differences with the Serbs amicably, and Marashli Ali Pasha concluded a gentleman's agreement with Milosh, who styled himself "supreme prince and ruler of the Serbian nation," the title being recognized (1815) by a national assembly. He rid himself of all his rivals and secured his own position. The Turkish regime was relaxed and Serbian autonomy enlarged until a *hatti-sherif* (1830) recognized Milosh as hereditary prince, besides granting Serbia other concessions and, in order to limit Milosh's powers, making provision for a council. Milosh enlarged Serbia by six districts (1833), paid a visit to the sultan and suppressed Mileta's rebellion but had to accept a constitution (1835). Considering this constitution too liberal, Austria, Russia and Turkey protested, and Milosh was glad to abolish it. In the meantime he decreed that land belongs to those who cultivate it. He wanted a council whose members would depend on him, whereas Russia wanted the members to be independent and appointed for life. Milosh tried to secure British help, but Russian pressure was decisive, and in 1838 Turkey granted Serbia a constitution agreeable to Russia. Milosh tried to abolish it by force but failed and was compelled to abdicate on June 13 (N.S.; 1, O.S.), 1839, in favour of his sickly son Milan Obrenovich II, who died 25 days later and was succeeded by his brother Michael (*q.v.*).

Milosh, who had made himself one of the wealthiest men in the

Balkans, went into exile. Michael followed him into exile in 1842, and Alexander Karageorgevich then became prince. Finally, however, when Alexander was compelled to abdicate Milosh, "the Old Master," was recalled to the throne on Dec. 23 (N.S.), 1858. After having spent nearly 20 years in exile, he had only enough time to show that his ideas remained unchanged. He died at Topchider, near Belgrade, on Sept. 26 (N.S.), 1860.

Whereas Karageorge had aimed at independence, Milosh, an illiterate political genius, was content with autonomy. In a period of transition he was the best man to bring this about. He owed everything to his political skill against the Turks and to his tyrannical energy. In the next stage, when justice, written laws, education and a good administration were essential, he could not adapt himself.

**MILOVANOVIC, MILOVAN** (1863–1912) Serbian statesman, prime minister in 1911–12 and an architect of the Balkan alliance, was born in Belgrade on March 1 (new style; Feb. 17, old style), 1863. He was the first Serb to qualify as doctor of laws in Paris. He was then elected professor at Belgrade university and, though only 25 years old, was mainly responsible for drafting Serbia's liberal constitution of 1888. Appointed undersecretary for foreign affairs in 1890 he kept that post until 1894 with a short interruption. He became minister of justice in 1896, but was dismissed in 1897. As a prominent Radical, he was sentenced *in absentia* to two years' imprisonment (1899). In 1900, however, he was appointed minister to Bucharest. As minister of national economy in 1901 he was one of the drafters of the new constitution. Having been minister to Rome from 1902 he represented Serbia at the second Hague conference in 1907 and was then elected a member of the Permanent Court of Arbitration. In 1908 he became foreign minister of Serbia. Finally, on July 8, 1911, he was appointed prime minister, retaining the portfolio of foreign affairs.

Milovanovic guided Serbian foreign policy through the crisis that followed Austria-Hungary's annexation of Bosnia-Hercegovina (1908); and he cleverly succeeded in raising internationally the question of Serbian national unification without provoking war with Austria-Hungary. Though a confirmed Russophil, he initiated the negotiations that led to a trade agreement with Austria-Hungary (1910). He was one of the chief founders of the Balkan alliance of 1912 insofar as it was he who negotiated the first Serbo-Bulgarian alliance of that year, though he died in Belgrade on July 1 (N.S.; June 18, O.S.), 1912, before a more substantial alliance could be concluded (*see* BALKAN WARS I.). He was the ablest statesman that Serbia had had since Prince Michael Obrenovich. Milovanovic published *Les Traités de garantie au XIX^e siècle* (1888), *Srbi i Hrvati* (1895) and *Srbi i Bugari* (1898).

**MILTIADES** (MELCHIADES), **SAINT,** pope probably from July 2, 311, to Jan. 10, 314, was born in Africa and was pope when edicts of toleration were published by Galerius, Constantine and Licinius. Constantine had him and bishops of Gaul and Italy judge the Donatists' charges against Caecilian, bishop of Carthage. (*See* DONATISTS.) Miltiades is considered a martyr because of earlier sufferings under Maximian; his feast is Dec. 11.

(W. M. K.)

**MILTIADES,** the name of two Athenian statesmen and generals of a family (the Philaidae) of Aeginetan origin, which claimed descent from Aeacus.

MILTIADES (6th century B.C.), the son of Cypselus, a prominent opponent of Pisistratus (*q.v.*). He founded an Athenian colony in the Thracian Chersonese (Gallipoli peninsula) at the request of the native Doloncians. He became tyrant of the Chersonese, which he fortified by a wall across the isthmus from Cardia to Pactya. He was captured by the people of Lampsacus, but released on the intervention of Croesus of Lydia. He was succeeded by Stesagoras, son of his half brother Cimon.

MILTIADES (d. *c.* 488 B.C.), the victor of Marathon, was another son of the Cimon mentioned above. He was probably archon in 524/523. On the death of Stesagoras, he was sent to the Chersonese (*c.* about 518–516) by Hippias—no doubt to support Hippias' half brother Hegesistratus at Sigeum. He imprisoned the chief men of the Chersonese, which was then in a turbulent condition, and married Hegesipyle, daughter of the Thracian prince Olorus. He led a contingent in the Scythian expedition of Darius I of Persia (*c.* 513) and, according to Herodotus, he advised the destruction of the Danube bridge, which would have cut off Darius' retreat. Since Miltiades was not at once expelled by the Persians, the story is doubtful and may have been invented for his trial. While ruling the Chersonese he seized the islands of Lemnos and Imbros for Athens. He supported the Ionian revolt from Persia and when it collapsed fled to Athens, where he was impeached (?493) by his political enemies for tyranny.

When the Persians sailed against Athens Miltiades was made one of the ten generals, and it was on his advice that the polemarch Callimachus decided to give battle at Marathon (*q.v.*). Subsequently he obtained a fleet of 70 ships from the Athenians, with a commission, according to Cornelius Nepos, to regain control over the Aegean. Herodotus says that, having besieged Paros unsuccessfully for nearly a month, he made a secret visit to Timo, a priestess of Demeter in Paros, with a view to the betrayal of the island, and being compelled to flee wounded himself severely in attempting to leap a fence. In any case, the siege was raised for some reason, and the Alcmaeonidae had him impeached on his return. All that is known is that he died of his wound (489/488), without paying the fine, which was paid subsequently by his son Cimon (*q.v.*). He appears to have been a man of strong determination and great personal courage, of a type characteristic of the time before the new constitution of Cleisthenes. His absence from the Chersonese during the first years of the new democracy (508–493?) and his aristocratic descent account naturally for the difference that existed between him and the popular leaders Themistocles and Aristides.

**MILTON, JOHN** (1608–1674), who ranks next to Shakespeare among English poets, was born in London, in Bread street, Cheapside, on Dec. 9, 1608.

**Family.**—Milton's grandfather, an Oxfordshire yeoman, had been a staunch Roman Catholic who disinherited his son, the poet's father, for turning Protestant. John Milton senior, going to London, made his way to prominence and a comfortable fortune as a scrivener or notary and through the collateral business of private banking or moneylending. Possibly the poet inherited a disposition toward religious independence, certainly he was given the best education, then six years of leisure and finally a continental tour. Milton paid repeated tributes, in verse and prose, to his father's generous concern. Another debt was in the way of music. The father was a composer, not of the first rank but still of enough repute to be a contributor to Thomas Morley's famous collection, *The Triumphs of Oriana* (1601); the poet's lifelong devotion to music is attested by the warmth of his own allusions and by his early biographers. Of his mother (d. 1637) Milton said only that she was well esteemed and known for her charities. He had an older sister Anne who married in 1623, and a younger brother Christopher who became a lawyer and, though a royalist, continued on good terms with him.

**Education and Early Poems.**—The conventional date given for Milton's admission to St. Paul's school, 1620, has no authority; it may have been as early as 1615. In addition to his regular schoolwork in Latin, Greek and—later—Hebrew, the boy had instruction at home, perhaps partly in modern languages, from private tutors, to one of these, the Scottish Thomas Young, he later wrote two letters and the Latin Elegy IV (1627), in which he gratefully recalled Young's introducing him to Latin poetry. Milton was from childhood a voracious student; he traced the initial

cause of his blindness to his having, from his 12th year, rarely quitted his books before midnight.

Along with a couple of Latin exercises that have survived, his earliest attempts at verse, made when he was 15, were rhymed paraphrases of Psalms 114 and 136. Milton's closest friend, at school and later, was Charles Diodati, the son of a prominent physician of Italian origin, who went from St. Paul's to Oxford; a less intimate friendship, which also lasted beyond school, was with Alexander Gill, the son of the headmaster.

On April 9, 1625, Milton matriculated at Christ's college, Cambridge; he received his B.A. degree in March 1629, his M.A. in July 1632. Young men of future distinction whose Cambridge careers more or less overlapped Milton's were Roger Williams, Thomas Fuller, Thomas Randolph and Jeremy Taylor and, at Christ's, John Cleveland and Henry More. Milton's experience at Cambridge can be partly gathered from his abundant Latin verse and his seven Latin prolusions (these were public speeches expected to display the speaker's learning and rhetorical and argumentative powers). The occasion of his first Latin elegy, addressed to Diodati, was his rustication, after a clash with his tutor, apparently in March 1626; at home in London, he compared his exile to that of his beloved Ovid and rejoiced in the opportunity to read the books (here classical plays) "that are my life" and to see beautiful girls while strolling. Evidently the college authorities did not find serious fault, since on his return he was assigned to another tutor and graduated in the normal time.

The nickname Milton acknowledged, "the Lady," no doubt referred to his handsome and delicate features and to a purity of mind and behaviour that disdained the diversions of his coarser fellows. During his seven years at Cambridge he seems to have moved from some unpopularity to general respect and, among dons and cultivated students, high esteem. He did not love the scholastic logic which largely dominated the university curriculum and which, in prolusions and later in *Of Education*, he denounced as barren. In his last prolusion (1631–32?) he proclaimed the fervent creed and dream of a young Renaissance humanist who was at once a Christian, a Platonist and—whether or not he had yet read Francis Bacon—a Baconian: it was in man's power to master all fruitful knowledge, to become an oracle of nations, a godlike ruler of nature.

Meanwhile Milton had been learning his art and sometimes revealing his inner self in writing Latin verse. Neo-Latin poets, such as George Buchanan or the contemporary Hugo Grotius (whom Milton later met in Paris, and whom posterity remembers as a jurist), enjoyed European fame; and college students commonly celebrated academic and national events in what was the normal language of the university world.

Milton's Latin poetry, with all its conventional rhetoric, sometimes attained higher levels than that of any other English practitioner. His small anti-Catholic epic of 1626, "In Quintum Novembris" (*i.e.*, on Guy Fawkes day), gives a vigorous if crude sketch of Satan and hell, and even formal obituaries on bishops inspire the Miltonic vision of heaven. Elegy V (1629), a picture of awakening spring, is aflame with the sexual imagery of an intense though innocent paganism. In Elegy VII (1627–28?) Milton presents himself as a confident foe of Cupid who is overcome by the beauty of a girl he encounters. The young poet's sensuous instincts were further displayed, along with his mastery of Italian, in six Italian sonnets (1630?), with which may be linked his first English sonnet, "O Nightingale."

*"On the Morning of Christ's Nativity."*—Early in 1628 Milton wrote the earliest of his extant English poems (apart from the two psalms), "On the Death of a Fair Infant," an elegy, in the Elizabethan vein, on his baby niece, Anne Phillips. In part of an academic prolusion in English couplets ("At a Vacation Exercise," July 1628) he declared his devotion to his native language, a style free from eccentricity, and exalted themes concerning nature and man. And in the Latin Elegy VI, addressed to Diodati in the festive Christmas season of 1629–30, he praised the light verse kindled by wine and love but turned from that to celebrate the ascetic purity of the heroic poet. The elegy ended with a reference to a poem he had just written, his first great poem in English, "On the Morning of Christ's Nativity." Such a poem, composed shortly after his 21st birthday, may be taken as a kind of announcement of his poetical coming of age and future direction, both in its religious theme and in its mastery of conception and form and image and rhythm. A short prelude enunciates, in terms of light, the supreme paradox of the Incarnation and leaps over time and space to link the poet's humble ode with the gifts of the three wise men. Then the hymn unfolds itself in three movements: the universal peace of the Roman world and all nature's awareness of its defects on the eve of its Creator's birth; the angelic song which, in symbolizing the new bond between heaven and earth, recalls the celestial music that attended creation and anticipates the trump of doom and the bliss of eternity; and, finally, the overthrow and flight of the pagan gods with the earthly advent of the true God. The last lines quietly reaffirm the central theme of divine order and harmony.

*"L'Allegro," etc.*—Probably in the long vacation of 1631 Milton wrote the companion poems, "L'Allegro" and "Il Penseroso." Less ambitious in theme than the "Nativity," they have their own complexity, concealed beneath a unique grace and charm. These celebrations of mirth and melancholy (really contemplation) transcend the traditions they belong to, the traditions of the encomium, the emblem, the prose "character" and the pastoral. The representative of mirth observes people, in pastoral sunshine or bright and crowded interiors; the contemplative solitary communes with himself and nature in twilight and with books through the night. But the "man" in each case is only a thread for the varied scenes and times and seasons that evoke or reflect the quality of the experience, and the descriptions are quite rightly generalized. The twin poems are related through abundant parallel and contrast; and the couplets, in trochaic and iambic lines of seven or eight syllables, trip and flow and pause with expressive ease. If the imagery and tone of the "Nativity" partake in some degree of the Italianate and Spenserian manner, these poems may be said to embody—and excel—the urbane, civilized decorum of Jonson's lyrical and reflective pieces—a quality already manifested in the tiny ceremonial "Song: On May Morning" (1629–30?) and the "Epitaph on the Marchioness of Winchester" (1631). In "L'Allegro" the learned Jonson is joined with "sweetest Shakespeare," the unlearned author of outdoor comedies (the plays that would appeal to the mirthful man). Milton had lately (1630) written the lines "On Shakespeare" which had the honour—the circumstances are not known—to be printed in the Shakespearian Second Folio (1632). The two elegies on Hobson the Cambridge carrier—whose death (1631) occasioned much student wit—were on a different level, of jocose punning.

Milton's scholarly and literary gifts had from childhood marked him out in the minds of his family and teachers for the ministry; in his later prose he said he had refused to "subscribe slave" in a church governed by prelacy, but the date of his negative decision is not known. As his academic career approached its end, the problem of an occupation would come up, and the poem "Ad Patrem"—though some scholars link it with *Comus* (1634)—may well have been written in 1631–32. In this piece, with a mixture of filial gratitude, firmness and confidence in poetry and himself, Milton assumes or urges that he would not be pushed into some basely lucrative profession by a father who has fostered his literary pursuits and is himself a devotee of the muses.

**Horton Period (1632–38).**—On taking his M.A. in July 1632, Milton retired to his father's house—perhaps first at Hammersmith, then the country estate at Horton, near Windsor, Berkshire—and proceeded to give himself the liberal education Cambridge had not provided. It was in these years that he laid the foundation or set the direction of his liberal thinking. With the humanistic zeal that had fired the seventh prolusion, he sought to digest the mass of history, literature and philosophy ancient and modern, to gain the "insight into all seemly and generous arts and affairs" needed by the citizen-poet who would be, no less than the cleric, a leader and teacher. At times he suspended his labours to visit London in quest of books or something new in mathematics or music.

An important landmark in Milton's early development is the

sober sonnet, "How soon hath Time," written on his 24th birthday, Dec. 9, 1632. During recent years he had become a figure in the small university world; now he writes this sonnet while his contemporaries are forging ahead and he has had six months of studious and outwardly unfruitful obscurity at home. But any uneasiness about his present and future is quieted in the earnest dedication of his life to his great Taskmaster's will. What might be called the first pledges toward the fulfillment of this self-consecration were two short religious poems, "On Time" and "At a Solemn Music" (1632–33). They have the form of a madrigal, a stanza of a *canzone*, and the irregular lines are powerfully modulated, so that every word has weight. The poems are early renderings of the beatific vision that always kindled Milton's imagination. Both, in different sequence, contrast the grossness of temporal life, the jarring discord of sin, with the eternity and harmony of heaven and good.

*Comus.*—The same contrast is sounded in the opening lines and carried through the whole of the masque known as *Comus*. During 1630–33, perhaps in 1632, Milton had, at the invitation probably of the musician Henry Lawes, written *Arcades*, a miniature masque of Jonsonian courtliness designed as a tribute to the dowager countess of Derby. *Arcades* presumably led to a request from Lawes for another masque. *Comus* was presented on Sept. 29, 1634, before the earl of Bridgwater at Ludlow castle in Shropshire, in honour of his becoming lord president of Wales. Lawes, the producer, acted the role of the Attendant Spirit; the parts of the Lady and the two Brothers were taken by the earl's children, of whom the eldest, Lady Alice Egerton, was only 15. The acting version, though somewhat shorter than the text familiar to readers, in length and elevated seriousness went far beyond the limits of the usual court masque, which emphasized lavish costumes, spectacle, music and dancing. Milton did provide such elements in some degree, and also, in Comus' rout of monsters, the "antimasque" often used as a grotesque contrast to ordered beauty, but his aim was not merely decorative. *Comus* was his first dramatizing of his great theme, the conflict of good and evil.

The Homeric and Ovidian Circe, whose power of changing men to beasts had long been allegorized as sensuality, becomes Comus ("revelry"), the son of Circe and Bacchus. Many sources have been suggested as contributing to Milton's mythological and pastoral fable—George Peele's *Old Wives' Tale*, Spenser's *Faerie Queene*, John Fletcher's *Faithful Shepherdess*, Jonson's *Pleasure Reconciled to Virtue*, William Browne's *Inner Temple Masque*, Erycius Puteanus' *Comus*, Tasso's *Aminta*, Italian musical dramas. But, from the first lines of the Attendant Spirit (who is a fusion of Neoplatonic daemon and Christian angel) to the incantatory epilogue, the conception and the poetry bear the clear impress of the author; they embody the crystal purity of his vision of perfection. The chastity the Lady represents is not mere abstinence; it is the positive love of the good that is both Christian and Platonic. Comus, who is projected with a dramatic irony that anticipates the treatment of Satan, puts forth specious naturalistic arguments which the Lady answers first on the rational level; then, with a conscious change of tone, she rises to an impassioned religious affirmation of "the Sun-clad power of chastity," and the epilogue celebrates the love of virtue which alone brings freedom and joy and the help of heaven. The best commentary on *Comus* is the personal passage in Milton's antiprelatical tract, *An Apology for Smectymnuus* (1642), where he tells how early reading had nourished his faith in chastity: he had loved and imitated the erotic poetry of Ovid and his fellows, but, while continuing to cherish their art, he had turned away from their sensuality to the idealism of Dante and Petrarch; then came the romances of knighthood (doubtless these included "our sage and serious poet Spenser"); and finally "the divine volumes of Plato" taught the true love of the good; and prior to and beyond all were "those chaste and high mysteries" glorified by St. Paul and the Book of Revelation.

*"Lycidas."*—If *Comus* was in a way a song of innocence, "Lycidas" (written in Nov. 1637) was a song of experience. Milton's first attempt to justify the ways of God to himself and to men. His former fellow collegian, Edward King, was drowned in a shipwreck in the Irish sea in Aug. 1637, and Milton was asked to contribute to a volume of elegies. "Lycidas," signed "J. M.," appeared at the end of an undistinguished collection of pieces in Latin, Greek and English (1638). The pastoral convention had, from its Greek beginnings, proved its value as a dramatic vehicle or mask for almost anything, public or private, that a poet wished to say, and Milton, working as usual within a venerable tradition, as usual re-created it. The pastoral devices—the lament of nature, the procession of mourners and so on—were accommodated to the Italian *canzone*, with its paragraphs and lines of irregular length and irregular rhyme. Dr. Johnson, in complaining of the absence of grief and the presence of pastoral artifice and a mixture of Christian and pagan allusion, missed the point entirely. Milton had no reason to feel deep personal sorrow for King had not apparently been an intimate friend; but the drowning of a virtuous and promising young man, on the threshold of service in God's church, brought home the whole enigma of life and death, of the rightness of things in a world where such events could happen. What if his own talents—which during his years of study at Horton he has been nurturing under his great Taskmaster's eye—should be cut off? Thus the "digressions" on fame and hireling clergy are not digressions but quite central in the emotional dialectic. In the end, God's justice and providence and the conditions of earthly life are vindicated not by reason, but by the beatific vision of Lycidas' soul received into heaven. A few bald sentences, however, cannot approach the complexities and depths of the poem, its reverberating solidity of reference, its rich variety of pace and tone, the artistic control that dominates turbulent emotions and ends with the high serenity of victory won. "Lycidas" may be the greatest short poem in the language.

**Italian Tour (1638–39).**—In May 1638, a year after his mother's death, Milton set off—with one servant—on a visit to Italy. He sojourned chiefly in Florence, Rome and Naples. Milton and some of his early poems—not those in English—were cordially welcomed among men of letters and patrons and their academies. The experience, which he described at length in the *Second Defence of the English People* (1654) and alluded to elsewhere, warmed his heart and nourished his self-confidence. (It may be remembered that at home he had very little literary acquaintance and, outside a small circle, no poetic reputation; his only writings in print were "On Shakespeare," *Comus*—published anonymously by Lawes in 1637—and "Lycidas," which was buried in the volume on King.) To his distinguished host in Naples, Baptista Manso, marquis of Villa, who had been the patron of Tasso and Marino, Milton wrote a bread-and-butter epistle, "Mansus" (1638–39), which is one of his best Latin poems, a graceful apologia for English culture and a no less graceful statement of his own poetic standing and hopes. He wrote also an epistle to a Roman poet, Salzilli, and several epigrams in praise of the singing of the famous Leonora Baroni. Though he mingled happily with Catholics, and was a guest at a grand entertainment given by Cardinal Barberini, the stout Protestant did not remain silent on matters of religion. He made a call—recorded in *Areopagitica*—on Galileo in his semicaptivity. Milton felt obliged to forgo a visit to Sicily and Greece because of news of mounting tensions in England, although, as he says, he lingered some time longer in Italy.

*Epitaphium Damonis.*—In Aug. 1638 Milton's friend Diodati (who had become a physician) died. Milton no doubt learned of his loss while in Italy; on his way homeward he stopped to see Diodati's uncle, John Diodati, professor of theology at Geneva. He returned to England in July 1639, and proceeded to settle in a house in London and prepare to take in pupils; the first ones were Edward and John Phillips, the sons of his sister Anne. His elaborate pastoral elegy on Diodati, *Epitaphium Damonis*, was written apparently late in 1640 and privately printed. This has commonly been ranked at the head of Milton's Latin poetry, though dissenters may ask if the fact of its commemorating his dearly loved friend has not heightened its intrinsic merits. There are expressions of heartfelt loneliness which are especially moving from a man often regarded as proudly self-sufficient; but in the poem as a whole Milton seems unable, perhaps because of the reality of his grief, to unify and re-create his pastoral material as

he had done so powerfully in "Lycidas."

**Prose Works.**—In his denunciation of hireling clergy in "Lycidas," Milton had virtually declared his Puritan allegiance, and the years 1641–60 he gave almost wholly to pamphleteering in the cause of religious and civil liberty. He had returned to England with anxiety about that cause, and also with plans for an Arthurian epic (plans set forth briefly in "Mansus" and *Epitaphium Damonis*); like other ambitious poets of the Renaissance, he hoped to write the great modern heroic poem. As he shows in the important personal passage in his fourth tract, the *Reason of Church-Government Urged against Prelaty* (1642), it was a heavy sacrifice to put aside his craving for poetic immortality and his cherished studies to "embark in a troubled sea of noises and hoarse disputes," but he could not be deaf to God's summons. And, as his work went on, he was sustained by the conviction that in his many and varied defenses of liberty he was, in another way, fulfilling his epic and patriotic aspirations.

The large bulk of Milton's prose—which fills four times as many volumes as his poetry—is read only by scholars, but much of it is important for several reasons. In an age of great prose, Milton's, at its best, has a very individual if often undisciplined greatness, and *Areopagitica* at least is a classic document and possession of the race. Then, even if he had never written any poetry, his prose works, though they had small influence in their own time, would remain a valuable interpretation of the Puritan revolution, and they have their place in modern histories of political thought. Finally, as the record of Milton's growth (a leftward growth, in religion and politics) and of his dreams and disillusionments, they are the essential introduction to *Paradise Lost*, *Paradise Regained* and *Samson Agonistes*, the bridge between the radiant idealism of youth and the much-tried faith and fortitude of age.

*Antiprelatical Tracts.*—In Nov. 1640 what was to be the Long parliament met and began its reform of abuses; it was soon confronted with a popular agitation against the bishops. During 1641–42 Milton contributed five pamphlets to the attack on prelacy made by the "Smectymnuus" group of Presbyterian divines (the word was composed of their initials, *ty* being Thomas Young, Milton's old tutor). The main issue was what had been the main issue since the emergence of Puritanism early in the reign of Elizabeth I: that the Church of England with its episcopal hierarchy and Prayer Book and ritual was a compromise with Rome (as it had been), and that the Reformation must be completed with a drastic purge of Romanism and a return to the democratic simplicity and purity of the apostolic church. Milton has all the Puritan emphasis on the inward spirit of biblical faith in contrast with outward show and spurious tradition; thus in the opening of his first tract, *Of Reformation Touching Church-Discipline in England* (1641), the Anglican service, so beautifully described in "Il Penseroso," has become "the new-vomited paganism of sensual idolatry." The tract ends with a vehement and magnificent prayer which proclaims Milton's glowing vision of a new and grand Reformation; he touches on his own role as the poet-singer of God's mercies and judgments, and his share in the millenarian dreams of his time appears in the apostrophe to "the eternal and shortly-expected King" who will reward his champions. All the main points come up in this pamphlet, though the *Reason of Church-Government* (1642) is a more ordered argument. It contains the memorable passage in which, with characteristically sublime naïveté, Milton explains his religious conception of poetry and the deferment of his projected epic because of public duty. The fifth and last tract, known under its abbreviated title *An Apology for Smectymnuus* (1642), lives chiefly in the passage cited above in connection with *Comus*, a self-defense that rises far above the refuting of opponents' charges of immorality.

*Tracts on Divorce; Marriage.*—Milton's first real notoriety came with his *Doctrine and Discipline of Divorce* (Aug. 1643; enlarged edition Feb. 1644), which was buttressed by three more tracts, *The Judgment of Martin Bucer, concerning Divorce* (Aug. 1644) and *Tetrachordon* and *Colasterion* (March 1645). Marriage—a prime concern of men in all ages—had been a signal concern of Reformation thought and one that Milton had reflected on in the Horton period (as entries in his Commonplace Book indicate). His discussion was presumably hastened by his own marital disaster. About May 29, 1642, several months before the outbreak of the Civil War, Milton had married Mary Powell, the daughter of a royalist squire of Oxfordshire who owed money to his father. Success could hardly be predicted for the marriage of a scholar and poet of 33 and an uneducated girl of half his age from a large, easygoing household. The young wife, visiting her family a little later, declined—doubtless with their backing—to return. The shock of the experience must have been especially severe for a man who—as one may infer from the anguished cries that recur in the *Doctrine*—had approached marriage not only with high hopes (and an unblemished past) but with earnest prayers; and there was no release from such a tragic mistake. In the tracts, Milton argued that the sole cause admitted for divorce, adultery, might be less valid than incompatibility, that the forced yoke of a loveless marriage was a crime against human dignity. Both religious and philosophic tradition and the way of the world (including the usually meagre education given to girls) kept woman inferior to man; Milton, without denying that view, upheld a personal and Puritan ideal of marriage as an active bond of mutual love and mental companionship, an ideal that exalted women and wives far above the level they occupied, say, in Cavalier poetry. He was, however, assailed as a new libertine by royalists and Presbyterians alike. In 1645 friends brought about a reunion between Milton and his wife; and in 1646, when the Powells had been ruined by the war, he took into his house, for nearly a year, the whole noisy family of ten. Three daughters, Anne, Mary and Deborah, were born in 1646, 1648 and 1652 (a son died in infancy); Mrs. Milton died a few days after Deborah's birth.

*Of Education and Areopagitica.*—In 1644 Milton published what are for modern readers his best-known pamphlets, *Of Education* (June) and *Areopagitica* (November). The former, written at the request of Samuel Hartlib, a man active on many progressive fronts, was one of the last in the long line of European expositions of Renaissance humanism. Milton's aim was the traditional aim, the molding of boys into enlightened, cultivated, responsible citizens and leaders. His proposed academy, which would take the place of both secondary school and college, was to be the model for many others. The main material was the ancient classics, in due subordination to the Bible and Christian teaching. The traditional role of physical and martial exercise was perhaps heightened by Milton's concern over the war in progress. Several points suggest some affinity with the especially Puritan movement toward practical education. While Milton could not share its illiberal hostility to the classics, he did want less gerund-grinding; also, objecting to a premature excess of logic, he planned a graduated advance from sense experience to abstract ideas; and, most conspicuously, he gave a large place to all kinds of science. If his program now seems unduly strenuous it must be compared, not with modern schools and colleges, but with contemporary practice and with the programs of earlier humanists, such as Rabelais.

*Areopagitica* (1644) is of course one of those tracts for the times that transcend their occasion. In 1637 the Star Chamber, reinforcing traditional censorship, put control of the press virtually in the hands of Archbishop Laud and the bishop of London. While the Long parliament abolished the hated Star Chamber, it was disturbed in its turn by the rising flood of unlicensed books, and, in order to maintain or regain its authority, it issued a new ordinance on licensing (June 14, 1643). In Aug. 1644 the Stationers' company (the guild of master printers) demanded stricter enforcement of this ordinance, naming Milton among transgressors. He had written his antiprelatical tracts as a Presbyterian, but in *Areopagitica* he saw the new censorship as only an exchange of episcopal for Presbyterian tyranny. Notwithstanding this disillusionment, he expresses a boundless faith in the Englishmen whom God has chosen to complete the Reformation Wycliffe had begun. With a still larger vision, Milton writes as a scholar and poet and lover of books, above all as a resolute believer in the power of truth to win its way through free inquiry and discussion.

(While this grand plea deserves its classic status, it is not the plea for complete freedom that modern libertarians sometimes make it; in vehemently denouncing censorship before publication Milton freely admits censorship afterward, since for him as for other liberals there must be safeguards for religion and morality.) Themes so near Milton's heart inspire soaring, richly figurative eloquence and also homely, richly figurative satire. In the whole work, cast in the form of a classical oration and addressed to parliament (as if to the Athenian assembly) with more than Milton's usual tact, the organization of topics and sentences alike has more deliberate order and clarity than his hurried prose commonly achieved. *Areopagitica* seems to have had very little effect in its own time—partly, perhaps, because the main theme of pamphlet controversy in 1644–45 was the problem of religious toleration raised by a group of Independent divines who sought congregational freedom from Presbyterian uniformity.

*Political Tracts and Secretaryship.*—In the next few years Milton may have been working chiefly on his *History of Britain* and his large treatise on Christian doctrine. By Feb. 13, 1649, two weeks after King Charles's execution, appeared his first political tract, *The Tenure of Kings and Magistrates*. In his first tract of 1641, Milton had written as a good monarchist, intent only on freeing the crown from the incubus of prelacy. By 1649 he had moved far enough to the left to expound the more or less democratic doctrine of Renaissance liberals, that power resides always in the people, who delegate it to a sovereign but may, if it is abused, resume it and depose or even execute the tyrant. Milton obviously rejected the Stuart claim of divine right; and his view of that abstract theorem, the social contract, was directly opposed to the view of such absolutists as Thomas Hobbes, who held that the people surrendered all rights. In the *Second Defence of the English People* (1654), surveying his earlier writings on liberty, Milton said that he wrote the *Tenure* to reconcile the public mind to Charles's execution, though the terms of his reference suggest the possibility that his own mind was not entirely at ease.

In March 1649, a month after the appearance of the *Tenure*, Milton was invited to become secretary for foreign languages to Cromwell's council of state. Hitherto a detached observer, Milton, in spite of his private studies, was doubtless eager to have a hand in the workings of government (his official experience has often been thought to have contributed to the realism of the fallen angels' debate). He was not on the policy-making level, but he had the easy command of Latin needed for foreign correspondence. Also, as a publicist of demonstrated sympathy with the revolution, he was expected to continue his defense of the cause against the multiplying attacks on the Commonwealth regicides.

Milton's first effort in this line was *Eikonoklastes* (Oct. 1649), one of a number of answers to *Eikon Basilike*, a book edited from the king's papers by his chaplain, John Gauden; this ostensible self-portrait of the royal saint and martyr, catching the public in its first shock of horror over the execution, was one of the most potent pieces of propaganda in English history, and not even Milton could prevail against it.

During 1651 Milton was censor and supervisory editor of the chief Commonwealth newspaper, *Mercurius Politicus*, edited by Marchamont Needham. In this year he became an actor on the European stage, with the publication of his Latin *Defence of the English People*. Charles II, in exile, had engaged Claudius Salmasius (Claude Saumaise), the most eminent of classical scholars, to arraign the regicides (*Defensio Regia pro Carolo I*, 1649). Milton was less effective in legal argument than in discrediting Salmasius by personal abuse; like some other crusaders, he tended to see opponents as monstrous enemies of a sacred cause who must be destroyed by any means. If he was, then and later, uplifted by the vanquishing of a renowned antagonist, he was inevitably and profoundly depressed by the loss of his eyesight; it had been failing for years and blindness became complete in the winter of 1651–52. Milton was only 43, and the great poem was still unwritten. Blindness reduced his strictly secretarial duties, though he continued through 1659 as a translator of state letters.

The *Second Defence of the English People* (1654)—also in Latin, since it also was addressed to Europe at large—was much more worthy of its subject and its author. It was a reply to an anonymous attack, *Regii Sanguinis Clamor ad Coelum adversus Parricidas Anglicanos* (1652), which Milton insisted on ascribing to Alexander More, though it was written by Peter Du Moulin (More had had a share in the business). Milton celebrated the achievements of the Commonwealth leaders in the heroic mood of his sonnets on some of them (Fairfax, Cromwell, Vane)—though he was bold enough to warn Cromwell against one-man rule; and, replying to the charge that he had brought on his blindness by immorality, he linked himself with the blind poet-seers of ancient myth in a passage that approaches the invocation to light in *Paradise Lost*. In *Pro Se Defensio* (1655), answering More's self-exculpatory attack, Milton tacitly accepted his denial of authorship but piled up evidence for his general responsibility and personal depravity.

Two tracts on church and state were published in 1659. In *A Treatise of Civil Power in Ecclesiastical Causes* (February), Milton argued that "it is not lawful for any power on earth to compel in matters of religion"; from such large toleration Roman Catholics were exempted, since Catholicism had shown itself a danger to national security. *Considerations touching the Likeliest Means to Remove Hirelings out of the Church* (August) reasserted, against an establishment and its tithes, the ideal of a clergy of apostolic simplicity of life. Much later, in *Of True Religion, Heresy, Schism, Toleration, and . . . the Growth of Popery* (1673), Milton pleaded for Protestant harmony and unity.

His last political pamphlet, *The Ready and Easy Way to Establish a Free Commonwealth*, was published in March 1660 and again, enlarged, in April. It was an act no less courageous than futile, since machinery was patently moving to bring back Charles II (he made his triumphal entry on May 29). Though Milton's outline of a republican constitution has historical interest, the modern reader's chief reaction is emotional. The tract is a cry of incredulity and despair from the last champion of "the good Old Cause." The glories of the Commonwealth, to which he himself had given 20 years and his eyesight, are being swept away by a nation of slaves "now choosing them a captain back for Egypt"—the "noble and puissant nation" whose faith and love of freedom he had so celebrated in his early pamphlets. The Restoration was the last and heaviest of Milton's many disillusionments.

Many things might be said of his religio-political thinking (and of its effects on later times), but only two can be here. The dynamic centre of his creed was "Christian liberty," a Reformation doctrine which he deepened and widened beyond its common limits. The superseding of the Covenant of Works by the Covenant of Grace is expounded in the *Christian Doctrine* (I, xxvii) and in a grand passage at the end of *Paradise Lost* (xii, 285–306). In brief, the Mosaic law was a primitive moral and ceremonial discipline imposed from above upon an untutored people; it is abrogated for the Christian, who, with the illumination of grace, is a self-governing agent, "freed from the yoke of human judgments, much more of civil decrees and penalties in religious matters." The revolutionary implications of such a creed are obvious—though one must not forget Milton's constant stress on inward discipline. A second point is that the revolutionary radical was not a democrat in the modern sense. He was a classical or "aristocratic" republican in whose ideal vision Platonic philosopher-kings coalesced with the Puritan "saints," and who found historical approximations in ancient Athens and Rome and some modern counterparts.

*De Doctrina Christiana.*—Milton's very large treatise, *On Christian Doctrine*, though now read only by students, held a central place in his thoughts and labours. He seems to have finished it by *c.* 1658–60. It was first printed and translated by Charles Sumner in 1825. But Milton apparently hoped that it might, in his own time, provide a solid basis of strictly biblical doctrine on which all Protestants could unite. For such a compendium he had special models in the work of Johannes Wollebius and William Ames. Granted his premises (which of course long ago lost their validity), Milton's treatise contains much acute argument; its modern importance is that it spells out with clear precision the

theology that operates in *Paradise Lost*. Viewed in a large perspective, most of Milton's essential beliefs are those of traditional Christianity, but—always on authority he finds in the Bible—he departs from orthodoxy on some notable points (not to mention polygamy): God created the world, not out of nothing, but out of his own substance; God the Father, the Son and the Holy Ghost are not a coequal Trinity but a descending order; man's soul dies with his body, until revived at the resurrection (this "mortalist" heresy, which is put into the mouth of the despairing Adam, had other adherents in Milton's England). The significance of the first point is that, in *Paradise Lost* (v, 469 ff.) as well as in the treatise (I, vii), Milton expounds a monistic and "optimistic" metaphysics, a sort of Christian materialism: since the one first matter of God's own substance is good, since all creation proceeds from God and, if not depraved from good, returns to him, matter is not essentially different from spirit but is forever in the process of becoming spirit. Milton's conception of the Trinity, which in itself and its background is too complex for summary, is apparent to alert readers of *Paradise Lost*, though the poem did not disturb generations of the orthodox. More basic for the poem is Milton's denial of Calvinistic predestination (which of course is not a heresy). Brought up, like most Anglicans of his time, as a Calvinist, he regarded himself as one at least until 1644, but his final belief was in the Arminian doctrine—the salvation, not of a predestined few, but of all believers, who constitute the true "elect." As one would expect of a man who had absorbed classical and especially Platonic ethics, Milton insisted on man's rational freedom and responsible power of choice (a main premise and theme of *Areopagitica*). His conception of "Christian liberty" was noticed in the preceding section. While the *Christian Doctrine* is an invaluable gloss on the epic, Milton the poet was well aware of the gulf between biblical truth and imaginative illustration; in the treatise Satan and the war in heaven received only a few lines.

**Sonnets and Other Poems (1642–58).**—Milton's early poems, English, Latin, Greek and Italian, were published at the beginning of 1646 (dated 1645). The loss of a gift copy on its way to the Bodleian library, Oxford, prompted an urbane Latin poem (1647) to John Rous, the librarian, a wartime meditation on poetry and culture that is somewhat akin to the sonnet of Nov. 1642, "Captain or Colonel." During the 20 years given to public affairs Milton was mostly cut off from poetry, but he wrote 17 occasional sonnets, versified a number of psalms and began the composition of *Paradise Lost*. Some of the sonnets on public men and events—for which Tasso had set an example—have been mentioned already; these, although so different in form, have the heroic tone of Horace's loftier odes (in Milton's hands, as Wordsworth said, the sonnet became a trumpet), and the leaders he salutes are invested with the large dignity of ancient heroes. "On the Late Massacre in Piedmont" (1655) is a tremendous imprecation that suggests the Hebrew prophets. Milton is sometimes consciously Horatian in the urbane geniality of addresses to young friends like Edward Lawrence and Cyriack Skinner; and the sonnets to Lady Margaret Ley and Henry Lawes further attest his genius for friendship. Several sonnets on the Presbyterian reception of his divorce tracts and on Presbyterian rigidity, are roughly colloquial journalism. At the opposite pole are the deeply personal sonnets, two on his blindness (1651?–55) and one on the death in 1658, some months after childbirth, of Milton's second wife, Katherine Woodcock, whom he had married in 1656. The major sonnets have much poetical as well as autobiographical interest, and as a group they illustrate (with "Lycidas") both in texture and rhythm the beginnings of the grand style which Milton may have learned partly from Della Casa and Tasso and which was to have full scope in the epic. One is less conscious of the sonnet structure and of rhymes than of a single massive unit which approaches a paragraph of Milton's blank verse.

**Later Life (1660–74).**—The Restoration government executed Sir Henry Vane and exhumed and hanged at Tyburn the bodies of Cromwell, Ireton and Bradshaw—acts of revenge apparently recalled in lines 693–696 of *Samson Agonistes*. Milton himself, as the noted defender of the regicides, was in real danger. In the summer of 1660, when a warrant was out for his arrest, he was kept in hiding by friends; and, though not excepted for punishment in the Act of Oblivion (August), he was later taken into custody (and released on Dec. 15). According to different early stories, his life was spared through the intercession of the poet Andrew Marvell, who in 1657 had become a fellow secretary and was now a member of parliament, or of the royalist playwright Sir William Davenant, whose life Milton had earlier been the means of saving. It may have been thought that the blind writer was now harmless and that nominal proceedings against him were enough; he was even said to have been offered a Latin secretaryship under Charles II. Milton's 14 remaining years were on the whole outwardly and in part inwardly peaceful, although, along with sombre or uplifting thoughts of past and present, there were concrete troubles, a frugal domestic economy necessitated by greatly diminished resources; blindness, and what was sometimes a more severe affliction, the pains of gout; and a degree of friction with his daughters, due probably to faults on both sides. Apart from the publication of books, the chief events of these years were Milton's marriage (1663) to a third wife, a young and amiable Elizabeth Minshull, who survived him, and the removal, during the plague of 1665, to a house at Chalfont St. Giles, Buckinghamshire (now a Milton museum). One cannot catalogue the 11 houses, including temporary lodgings, that Milton occupied in London.

Early biographers give pictures of a quiet daily routine. Milton got up at 4 A.M. and had the Hebrew Bible read to him. Meditation, reading and dictation filled the time till midday dinner. Milton's late and long poems were of course composed in his head, especially at night, as famous allusions in *Paradise Lost* indicate (according to his nephew, Edward Phillips, his vein flowed happily only from the autumnal to the vernal equinox); when he was ready "to be milked," he would dictate, often with one leg flung over the arm of his chair. The taking of dictation, the correcting of copy, and reading aloud in various languages were services performed by paid amanuenses, his two nephews, his daughter Deborah and friends and disciples. After dinner, says John Aubrey, "he used to walk 3 or 4 hours at a time (he always had a garden where he lived)." In the evening there was reading of poetry and he went to bed about 9, after a pipe and a glass of water. One refreshment was music, playing on the organ or viol and singing; "he would be cheerful even in his gout fits, and sing" (Aubrey). And there were many, sometimes too many, callers—foreigners (who came to see the conqueror of Salmasius, not the poet) and English friends, old and young, such as men already mentioned and the young Quaker, Thomas Elwood, whom Milton helped with his Latin. He was, Aubrey reports, "Extreme pleasant in his conversation, and at dinner, supper, etc.: but satirical"; "He pronounced the letter R (*littera canina*) very hard ('A certain sign of a satirical wit'—from John Dryden)." In religion Milton had moved from the low-church Anglicanism of his parents to Presbyterianism to Independency to independence. In the latter part of his life, said John Toland, "he was not a professed member of any particular sect among Christians, he frequented none of their assemblies, nor made use of their peculiar rites in his family." But, as Dr. Johnson observed, suspending his Anglican hostility, "his studies and meditations were an habitual prayer." Milton died on Nov. 8, 1674, "of the gout struck in" (Aubrey), a month short of his 66th birthday. His burial in St. Giles's, Cripplegate, was attended by "All his learned and great friends in London, not without a friendly concourse of the vulgar" (Toland).

The publications of Milton's late years were: *Paradise Lost* (1667), for which he received £10; textbooks of simplified Latin grammar (1669) and logic (1672); the *History of Britain* (1670); *Paradise Regained* and *Samson Agonistes* (1671); the second, enlarged edition of the *Poems* of 1645 (1673); the second, revised edition of *Paradise Lost* (1674); and *Epistolae Familiares* with the *Prolusiones Oratoriae* (1674). *A Brief History of Moscovia* appeared in 1682. A Latin dictionary on which Milton had long worked was completed by others and published in 1693. Edward Phillips translated *Letters of State, written by Mr. John Milton* (1694), with a life.

**Paradise Lost.**—Milton gave up the idea of a British epic described in "Mansus" and *Epitaphium Damonis*. Among nearly 100 biblical and historical subjects for dramas that he set down *c.* 1640, he chose the most momentous event, next to the life and death of Christ, in the world's history. He outlined dramatic treatments of this theme in four short drafts which suggest Italian allegorical representations of biblical story, such as G. Andreini's *L'Adamo* (1613). Edward Phillips recorded that part of Satan's address to the sun (*Paradise Lost*, iv. 32–41) was written early as the opening speech of a drama. In shifting to the epic Milton may have been impelled by the supreme place that form held in Renaissance theory and by his own need for larger scope. It is not known when actual composition began; guesses have centred on 1655–58. Clearly the lines on the poet's having fallen on evil days, in the prelude to book vii, were composed after the Restoration, and presumably the whole was done pretty much in the order in which it stands. It was finished by 1665. The first edition of 1667 was in ten books; this was reissued in 1668 and 1669, and in one of the 1668 issues Milton added the prefatory note on his use of blank verse and the arguments. In the second edition (1674), along with some small revisions, books vii and x were each split into two; and the arguments, formerly grouped together, were placed at the head of the respective books.

The fall of man had for many centuries received copious theological commentary and innumerable imaginative treatments, narrative and dramatic, so that the simple tale in Genesis and the more shadowy role of Satan in heaven, earth and hell had acquired a good deal of interpretative and concrete embellishment. One late, long and popular example which Milton had known in boyhood is the crudely vigorous poem on the creation and the fall by the Huguenot Guillaume Du Bartas, which, translated by Josuah Sylvester as *The Divine Weeks and Works* (1605), held sway in England until superseded by *Paradise Lost* (line 373 in book iii is identical with a line in Sylvester). And Milton would surely have read Grotius' drama, *Adamus Exul* (1601). His knowledge of both the theological and the literary tradition was probably extensive but can seldom be pinned down; from time to time this or that work has been claimed as his "source," yet the inevitable family resemblance among the numerous poetic versions negates or discounts most such claims. The general fact is that the main motives and events of *Paradise Lost* had more or less precedent, though they were handled with powerful originality; Milton, like a Greek dramatist, was reworking a story familiar in outline to his audience. His story, moreover, was one of unique truth, sacredness and universal and eternal import, and it gave the poet the advantage of immemorial belief and association in the minds of his earlier readers, an advantage that no longer operates in the same way—although, for modern readers, the fable possesses the immemorial and universal import of archetypal myth.

Notwithstanding the accumulated embellishments, and the anthropomorphic nature of the nonhuman personages, the story had little of the solidity and variety of character and action of the classical epics, and Milton the classicist naturally took over much in the way of form and style and epic convention. While he was said to have known the Homeric poems by heart, and often echoed them, the great neoclassical model was the *Aeneid*, with which *Paradise Lost* has some inner as well as surface affinities. As Virgil, with his partly abstract theme, re-created what he imitated from the concrete Homer, so Milton, with his far more abstract theme—the assertion of Eternal Providence, the justification of God's ways to men—re-created what he borrowed from both. Thus invocations of the muse, which in Milton mark new stages in the story or changes of scene, become addresses to the heavenly muse, Urania, and prayers for the aid of the creative spirit of God. As artist, he links himself, both proudly and humbly, with the ancients, especially Homer and the blind bards of Greek myth, but he regularly ranks his Christian theme above the themes of the pagan poets. As he had said long before, in explaining why he must postpone his epic, it was a work not "to be obtained by the invocation of Dame Memory and her Siren daughters, but by devout prayer to that eternal Spirit who can enrich with all utterance and knowledge, and sends out his seraphim with the hallowed fire of his altar, to touch and purify the lips of whom he pleases."

Some other large features of the classical and especially Virgilian pattern must be mentioned. Milton makes daring use of the prescribed plunge *in medias res*, since he gives the magnificent first two books to his "villain." Virgil has a roll call of the Italian chiefs who gather to oppose the heaven-sent Aeneas; Milton's roll call of the leaders of the fallen angels, in making them individuals, also becomes a survey of the spread of heathen idolatry over the eastern world. The realistic power of the debate in hell dwarfs all other epic councils. Epic accounts of Hades and of funeral games are combined in Milton's pictures of hell, with Christian lore, but the lurid and dismal scenes and the physical and mental diversions of the fallen angels symbolize their spiritual death and futile striving. The wars of gods and Titans and giants supply details for the war in heaven, which is a large metaphor for the anarchy of sin. The story of events that preceded the opening of the poem, which Odysseus recapitulated at the court of Alcinous and Aeneas at the court of Dido, becomes the archangel Raphael's account of Satan's revolt and war and the Son's creation of the world; and the great object lesson for Adam is underlined by a discourse on astronomical uncertainties which contrasts humble righteousness with the prideful quest of external knowledge. Finally, while a prophetic picture of human history might figure in stories of the fall, Michael's revelation to Adam (books xi–xii) recalls Anchises' revelation to Aeneas; but whereas Aeneas learns of the divinely destined Roman *imperium*, Adam is shown supernal grace contending with the sinfulness of men and the eventual triumph of love with the advent of man's Redeemer—though he is shown too how the gospel of salvation becomes corrupted.

The prime example of this kind, though it goes far beyond classical parallel and contrast, is the characterization of Satan, who is one of the supreme figures in world literature. Satan has, on a superhuman scale, the strength and courage and capacity for leadership that belong to the ancient epic hero, but these qualities are all perverted in being devoted to evil and self-aggrandizement. Satan's character is presented partly through narrative and comment and heroic or—later—animal simile (and many of our most vivid visual memories of the poem are of Satan in his various postures and settings). But there is also the full dramatic self-revelation familiar from Shakespeare's villains, and Satan's speeches at moments remind the reader of Richard III, of Iago and Edmund, of Macbeth. Thus in his first grand speech to his lieutenant Beelzebub, Satan's defiance of God manifests in every phrase his egoistic pride and passion, his false conception of freedom, his alienation from all good, and his other public harangues reinforce and amplify our sense of power that is religiously and morally corrupt and blind. Against the background of hell, Satan maintains (up to the final, wholesale metamorphosis that follows his return from earth) the false magnificence of his "heroic" stature; outside of hell he loses even that. In his soliloquy addressed to the sun he reveals, like Dr. Faustus or Macbeth, his despairing consciousness of his own evil and damnation, a consciousness that gives him potentially tragic dimensions, though he is not allowed to become, like Macbeth, a truly tragic figure. Thus Satan (in his usual public role) and his fellows are enveloped in dramatic irony, because—though the corruption of man is achieved—they fight and scheme in ignorance of the issues at stake, in ignorance of the unshakable power of God and goodness.

Adam and Eve are enveloped in a partly parallel kind of irony. The picture of Eden is a symbolic rendering of Milton's vision of perfection, but it is presented when the reader accompanies Satan into the garden, so that idyllic innocence and happiness are seen only under the shadow of evil. Though the pair have had warnings, Eve is beguiled by an appeal to her vanity and ambition, by the hubristic dream of attaining godlike knowledge and power; and Adam, whose stronger reason is aware of the issues, allows his love for Eve to oversway his love for God. Both, far from attaining godlike knowledge, succumb to animal lust; yet, when grace and penitence begin to work in them, they have a strength

beyond the reach of Satan. On the other hand, though there is promised redemption for the faithful, and though the poem is, logically, a divine comedy with a happy ending, Milton's panorama of human history gives little ground for hope on earth. Irony, profoundly compassionate irony, pervades the simple, complex and moving last lines which describe Adam and Eve as they depart from Eden—not now the majestic lords of creation but two frail human beings beginning life anew in the world of sin and sorrow and death, though "with Providence their guide" and the hope of achieving a "paradise within."

The more one reads *Paradise Lost* the more one recognizes Milton's powers of imagination and organization. Everywhere, on the largest or the smallest scale, in abstract idea or concrete act, theme and material are closely knit through parallel and contrast. The central conflict and contrast between good and evil are reflected and intensified in the contrasts between heaven and hell, light and darkness, order and chaos, love and hate, humility and pride, reason and passion. In the council in hell, Satan alone volunteers for the perilous journey to earth to bring about the fall of man; in the council in heaven, the Son alone volunteers to suffer on earth for man's salvation. Satan and Sin and Death, at the gates of hell, constitute a monstrous and abhorrent parody of the Trinity; when Sin and Death build a bridge from hell to earth, their new domain, they hover upon the waters, like the spirit of God at the creation. Satan unlooses the destructive anarchy of war; the Son creates the world. Eve and Adam reenact the sin and fall of Satan. The boundless scene of *Paradise Lost* is indeed only a backdrop or magnified reflection of the drama that goes on in the hearts of the human protagonists; and when they fall, the ideal world of eternal spring and eternal life becomes the world we live in.

To speak of the setting in more literal terms, Milton's imagination fills space so immense that the created universe—the Ptolemaic one—hangs from heaven like one of the smallest stars close by the moon. Milton showed his awareness of the Copernican universe but the Ptolemaic had the advantages of traditional familiarity and of keeping earth and man at the focal centre. In his handling of vast space Milton's imagination and language work with a suggestive vagueness (mixed with the substantial and concrete) that is very different from the minute particularity of Dante's world. He is excited by the starry dance of the cosmic order, and likewise by the fecundity of Eden; and the account of creation is alive with the sense of movement and growth. The poem is rich in its appeal to the eye—and other senses—as well as to the ear.

Milton's preface stressed the novelty and rightness of blank verse for a heroic poem, and his manipulation of rhythm and sound is of course one of his supreme achievements. The continuous flow of his long sentences and paragraphs is naturally unlike the dramatic blank verse of Shakespearian dialogue, and it builds up a continuous onward pressure. Some main elements of Milton's technique had been conspicuous in his sonnets, in spite of their pattern of rhyme. While the iambic pentameter line remains in one's ear as the norm, there may be extra syllables, and there is endless variety in the number, weight and position of stresses. At the same time there is a secondary and still more fluid system of rhythmic units, which flow from the caesura in one line to the caesura in the next. The principle stated thus baldly means in practice, an infinity of permutations and combinations. As a modern master of rhythm, T. S. Eliot, has said, Milton's blank verse is never monotonous. And the pattern of sound is so wedded to the pattern of sense that each is essential to the other.

Milton's frequently Latinate syntax and diction have sometimes been censured, especially by modern poets and critics for whom colloquial speech and rhythm are the only acceptable medium (though this is in fact no less "artificial" than the grand style). Milton had both ancient and modern (especially Italian) tradition on his side. Homer and Virgil were, in their different ways, thoroughly stylized, and such moderns as Tasso had practised and critically expounded the various ways of achieving the elevation required by a lofty theme. Miltonic elevation is rarely inflation; and it is intermixed with pure simplicity. Latinate syntax or structure, freedom in the placing of phrases and clauses, does not obscure the sense and greatly enlarges and enriches the poet's range of emphasis, the means of economy, contrast, suspension, all the devices of forceful utterance—devices often really colloquial. Many other and likewise functional elements of the grand style could be noted: periphrasis, epic similes, geographical, historical and mythological allusions, etc.

**Paradise Regained.**—In *Paradise Lost* (ix) Milton spoke of "patience and heroic martyrdom" as themes unsung, though nobler than martial prowess, and this "better fortitude" was celebrated in *Paradise Regained* and *Samson Agonistes* (1671). Presumably both works were composed after *Paradise Lost*. In the *Reason of Church-Government* (1642) Milton had named the Book of Job as a model for a brief epic, and its influence is clear in both. *Paradise Regained* is a logical sequel to the long poem since Christ, the second Adam, wins back for man what the first Adam lost. But Milton did not, as his title and theological tradition might suggest, deal with the Crucifixion; instead he showed Christ in the wilderness overcoming Satan the tempter, thereby proving (by God's design) his fitness for his ultimate trial and, in his human role, proving what man in general might achieve through strong integrity and humble obedience to the divine will. Milton followed Luke's version. The first temptation, to change stones into bread, would imply distrust of Providence. The second temptation, that of the kingdoms of the world, Milton extended into a series—a gorgeous banquet, wealth, glory, the delivery of Israel from the Roman yoke, alliance with Parthia or Rome, the imperial throne and, finally, the wisdom of Greece. Christ is proof against all of these. "To the utmost of mere man both wise and good." Dramatic tension has been built up by Satan's tormenting doubts of his antagonist's identity and mission, and also by Christ's own deepening knowledge of both and by our mounting sense of his isolation. The third temptation, that of standing on the pinnacle of the temple, is a challenge which, with dramatic suddenness, reveals Christ's divinity to both Satan and himself. This poem, less of an epic than a drama with elaborate stage directions, is cast in a style of almost gospel simplicity. The mass of readers and critics seem to have found it cold, though it has all the fire of Milton's religious and moral passion, his reverence for true heroism. Many, too, have been upset by Christ's repudiation of the Greek culture which Satan praises in language that seems to come, and does come, from the poet's own heart; but Milton had always, like other Christian humanists, ranked the literature and natural wisdom of antiquity below the Bible and Christian faith. There is a scale of values.

**Samson Agonistes.**—That Christ's rejection of Greece is relative, not absolute, is shown by the fact that *Samson*, in the same volume with *Paradise Regained*, is in the pattern of Greek tragedy, which (along with Italian) Milton extols in his preface. *Samson*, by far the greatest English drama on the Greek model—and, for some readers, the most powerful and completely satisfying of Milton's major works—has affinities with all three of the Greek masters because the poet did not "get up" the technique for the occasion; he wrote out of lifelong saturation and as the Christian peer of the ancients. But the drama recalls especially Aeschylus' *Prometheus Bound* and Sophocles' *Oedipus at Colonus*. Always a strict observer of "decorum," Milton admits no specifically Christian idea, attitude or allusion; his hero, to be sure, is not at all the brawny barbarian of the Book of Judges, but he remains Hebraic—with touches, toward the end, of a calm reasonableness that reminds one of Socrates in prison. The action, up to the reported catastrophe, is wholly psychological; it is the process by which Samson, "Eyeless in Gaza at the mill with slaves," moves from preoccupation with his misery and disgrace to selfless humility and renewed spiritual strength, so that he can once more feel himself God's chosen champion. Still more clearly than the Christ of *Paradise Regained*, Samson is isolated; not even his father or the chorus perceives the true inwardness of his experience. The whole drama is charged with more than Sophoclean irony. Every scene has an effect different from that expected by

the interlocutor; and countless details, from the title and the first line onward, are potently ambiguous. Though the subject had long been in Milton's mind, the drama must owe a good deal of its power to his sense of kinship with his hero; he has been eyeless in London among a nation of slaves. But nowhere does the classical impersonality and restraint of Milton's art show itself so strongly; there is nothing in the drama that does not belong to the story of Samson. And Milton's classical style appears in a new phase, in a rugged, sinewy, colloquial texture and in irregular rhythms of new expressiveness. Altogether, if *Samson* was his last work, it was a grand testament. Like Samson, Milton was able to conquer despair, or to sublimate it in his last three poems. These expressed, not his earlier revolutionary faith in men and movements, but a purified faith in God and the regenerative strength of the individual soul.

**Miltonic Criticism.**—Much of the older criticism, down into the 20th century, is mainly of historical interest and may give modern readers less insight into the poet than into the critic and his cultural climate; but Milton's fame and influence are part of the history of English literature and culture (and libertarian thought). Since criticism in the modern sense was only being created by his young contemporary, Dryden, there is little early testimony: Sir Henry Wotton's praise of *Comus* (in the letter prefixed to the *Poems* of 1645), Marvell's commendatory lines on *Paradise Lost* (1674), Dryden's epigram linking Milton with Homer and Vergil and his more restrained comments in prose, and a few anecdotes. Of special interest is Dryden's report (preface to the *Fables*): "Milton has acknowledged to me that Spenser was his original"—*i.e.*, general model. But Milton's growing eminence is attested by the series of early biographies (*Early Lives of Milton*, ed. by H. Darbishire, 1932): the anonymous manuscript first printed in 1902 (assigned by Miss Darbishire to Milton's nephew, John Phillips, but claimed by W. R. Parker for Cyriack Skinner); the notes, printed in 1813, of the lively and careful John Aubrey; and the lives by Anthony à Wood (1691), who has next to no original value, Edward Phillips (1694), John Toland (1698) and Jonathan Richardson (1734).

Patrick Hume's annotated edition of *Paradise Lost* (1695)—one of Jacob Tonson's five editions of 1688–98—was the first scholarly edition of any English poet. Richard Bentley's edition (1732) was the disastrous attempt of a great classical scholar to emend a supposedly corrupt text. Better evidence of Milton's classical standing was Bishop Newton's variorum edition of the poems (1749–52) and Thomas Warton's edition of the early poems (1785; rev. 1791). Criticism proper began with Addison's papers on *Paradise Lost* in *The Spectator* (1712) in which, accepting Milton as the peer of the ancients, he applied neoclassical theory, noted classical parallels and praised "beauties." Addison was a prime agent in extending Milton's fame on the continent. Dr. Johnson's treatment (*Lives of the Poets*, 1779) suffered from his political and religious prejudice and from some critical failures of understanding, but it retains the value of its author's massive honesty and genuine if limited insight. Milton's enormous influence on 18th-century verse is traced by R. D. Havens, *The Influence of Milton on English Poetry* (1922).

The 19th century opened with H. J. Todd's variorum edition of the complete poems (1801; rev. 1809; 5th ed., 1852), which is still useful, and may be said to have closed with David Masson's important edition (1890). Masson's *Life* (6 vol., 1859–80, with revised editions of the first 3 vol. and an Index, 1881–96) is subject to correction on many things, but it was a great achievement and remains of much value for Milton's life and times.

Nineteenth-century criticism includes many notable names, such as Hazlitt, Coleridge, Keats, Landor, Macaulay, Emerson, Bagehot, Arnold, up through the larger and more professional studies of Mark Pattison (1879) and Sir Walter Raleigh (1900). A brief summary may divide criticism of the 19th and the early 20th century into two main streams. First, the revolutionary romantics, Blake and Shelley, launched the "Satanist" misinterpretation of *Paradise Lost* and its author which is summed up in Blake's saying that Milton was of the Devil's party without knowing it; that is, Milton—as a rebel like Blake and Shelley—projected himself into Satan, his real hero. The other main attitude, also focused on the epic, was also a product of 19th-century liberalism: its exponents threw Milton's beliefs and ideas overboard as long-dead fundamentalism and listened only to the organ voice.

Milton's influence, which had worked from about 1650 up through the romantic poets, largely waned in the Victorian age. In the 20th century the new poetry and criticism inaugurated by Ezra Pound and T. S. Eliot was strongly anti-Miltonic and pro-Donnian, but in the 1940s and 1950s critical activity shifted markedly from Donne back to Milton. Scholarship, going its own way, had already discovered "the new Milton." The movement in scholarship and scholarly criticism which began about 1920 and which (in the late 1950s) showed no sign of exhaustion, produced a vast and varied array of general and special studies; these placed the thinker, the publicist and the poet firmly and significantly in the history of ideas, exterminated the romantic notions touched on above, and brought a new refinement of perception and analysis to the aesthetic study of the poetry (though a poet steeped in the classics may have fared better, in that area, with the older critics). A conspectus is provided in James Thorpe, *Milton Criticism: Selections From Four Centuries* (1950).

*See* also references under "Milton, John" in the Index.

BIBLIOGRAPHY.—*Editions:* The standard edition of the complete works is that of the Columbia University editors, 18 vol. and a valuable Index (1931–40). H. F. Fletcher edited a facsimile edition of the complete poems, 4 vol. (1943–48). *Poetical Works*, ed. by H. Darbishire, 2 vol. (1952–55), has mainly textual apparatus. The complete prose is fully annotated in the Yale edition, ed. by D. M. Wolfe *et al.*, 8 vol., vol. i (1953). *The Student's Milton*, ed. by F. A. Patterson (rev. ed., 1933), has almost all the works, with some apparatus, in one volume. Among countless annotated editions of the poems and selected prose are those of M. Y. Hughes, 3 vol. (1935–47; 1 vol., rev. and enl., 1957, with full introductions and bibliographical references). *Milton's Poems*, ed. by B. A. Wright (1956), is an expert modernized text.

*Bibliographies:* D. H. Stevens, *Reference Guide to Milton From 1800 to the Present Day* (1930); *Cambridge Bibliography of English Literature*, ed. by F. W. Bateson, 4 vol. (1941), and the *Supplement*, ed. by G. Watson (1957); bibliographies in many of the books cited above and below; and the annual bibliographies of the Modern Humanities Research Association (1920 *et seq.*), *Studies in Philology* (1922 *et seq.*) and *Publications of the Modern Language Association of America* (1922 *et seq.*).

*Criticism:* Of the library of reference works and important studies, general and special, only a representative few can be mentioned here. There is a one-volume biography by J. H. Hanford, *John Milton, Englishman* (1949). J. M. French's *Life Records of John Milton*, 5 vol. (1949–58) is an exhaustive collection of documents, references, etc. A special study is D. L. Clark, *John Milton at St. Paul's School* (1948).

A large body of scholarship and criticism digested in a 3-vol. variorum commentary on all the poems (the first since Todd), vol. i (1960); the most compendious small digest is *A Milton Handbook*, 4th ed. (1946), by J. H. Hanford, a leader in the modern reinterpretation of Milton. Some general and miscellaneous studies are: Robert Bridges, *Milton's Prosody*, rev. ed. (1921); E. M. W. Tillyard, *Milton* (1930), *The Miltonic Setting* (1938) and *Studies in Milton* (1951); D. Bush, *English Literature in the Earlier Seventeenth Century*, ch. 12 (1945); I. Samuel, *Plato and Milton* (1947); S. E. Sprott, *Milton's Art of Prosody* (1953); D. C. Allen, *The Harmonious Vision* (1954); K. Muir, *John Milton* (1955); K. Svendsen, *Milton and Science* (1956); D. Daiches, *Milton* (1957). T. S. Eliot's essays of 1936 and 1947 are reprinted in *On Poetry and Poets* (1957).

*Early Poems:* J. H. Hanford, "The Youth of Milton," in *Studies in Shakespeare, Milton and Donne* by O. J. Campbell *et al.* (1925); A. S. P. Woodhouse, articles on *Comus*, *University of Toronto Quarterly*, xi (1941), Milton's early development, *University of Toronto Quarterly*, xiii (1944), Milton's pastoral monodies, *Studies in Honour of Gilbert Norwood* (1952); C. Brooks and J. E. Hardy, *Poems of Mr. John Milton* (1951); R. Tuve, *Images and Themes in Five Poems by Milton* (1957).

*Prose Works:* A. S. P. Woodhouse, *Puritanism and Liberty* (1938; 2nd ed. 1950); A. Barker, *Milton and the Puritan Dilemma* (1942); Z. S. Fink, *The Classical Republicans* (1945); W. Haller, *The Rise of Puritanism* (1938) and *Liberty and Reformation in the Puritan Revolution* (1955); Yale edition (above).

*Paradise Lost:* M. Kelley, *This Great Argument* (1941), on the *Christian Doctrine* and the poem; C. S. Lewis, *A Preface to Paradise Lost* (1942); E. E. Stoll, *From Shakespeare to Joyce* (1944); Sir M. Bowra, *From Virgil to Milton* (1945); D. Bush, *Paradise Lost in Our Time* (1945); J. S. Diekhoff, *Milton's Paradise Lost: a Commentary on the Argument* (1946); R. Ralph, *Paradise Lost and the Seventeenth Century Reader* (1947); W. Kirkconnell, *The Celestial Cycle: the Theme of Paradise Lost in World Literature* (1952); A. Stein, *Answerable*

*Style* (1953); A. S. P. Woodhouse, "Pattern in Paradise Lost," *University of Toronto Quarterly*, xxii (1953); F. T. Prince, *The Italian Element in Milton's Verse* (1954).

*Paradise Regained*: E. M. Pope, *Paradise Regained: the Tradition and the Poem* (1947); H. Schultz, *Milton and Forbidden Knowledge* (1955); A. S. P. Woodhouse, "Theme and Pattern in *Paradise Regained*," *University of Toronto Quarterly*, xxv (1956); A. Stein, *Heroic Knowledge* (1957).

*Samson Agonistes*: W. R. Parker, *Milton's Debt to Greek Tragedy in Samson Agonistes* (1937); A. S. P. Woodhouse, articles in *Transactions of the Royal Society of Canada*, 3rd series, xliii (1949) and *University of Toronto Quarterly*, xxviii (1959); A. Stein, *Heroic Knowledge* (1957).)

(D. Bu.)

**MILTON,** a town of Norfolk county, Mass., U.S., located on the Neponset river 7 mi. S. of Boston on hilly terrain that falls gently down to the river from the Blue hills in the south. Settled in 1636 as a part of Dorchester and known by the Indian name of Unquity-quisset, the town of Milton was incorporated in 1662. It soon grew into a mill town and in the 18th century was an important small industrial centre. Industrial activity decreased during the 19th century with the important exception of stone cutting. Stone for the Bunker Hill monument was quarried in Quincy, cut in Milton and transported by the Granite railway, the first railroad chartered in the U.S.; motive power was furnished by horses and oxen.

In the late 19th century Milton became a wealthy suburb of Boston. The large estates were gradually broken up after 1930 and Milton became a suburban community with a small amount of manufacturing. Milton academy (boys) and Milton Academy Girls' school are located there. Blue Hill observatory was established in 1885. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (L. G. Ba.)

**MILWAUKEE,** the largest city of Wisconsin, U.S., is located on the west shore of Lake Michigan, 85 mi. N. of Chicago; a port of entry and seat of Milwaukee county. Population (1960) city 741,324; standard metropolitan statistical area (Milwaukee and Waukesha counties) 1,194,290, to which Ozaukee county (1960 pop. 35,441) was added in 1963. (For comparative population figures *see* table in WISCONSIN: *Population.*)

The city proper is entirely within Milwaukee county and almost wholly hemmed in by incorporated suburbs, including Wauwatosa and West Allis (*qq.v.*). The altitude of 580 ft. at lake level rises 75 to 125 ft. to the west. Three rivers cut the city into natural divisions: the Milwaukee river, entering from the north, is joined half a mile from its mouth by the Menomonee flowing from the west, and nearer the lake by the Kinnickinnic from the south; it empties into Milwaukee bay, about 6 mi. wide. Commercial and industrial property lines the banks of these streams in their navigable, downtown sections. A large part of the lake front was reclaimed or redeveloped for parks and municipally owned outer harbour facilities, including Lincoln Memorial drive. The Court of Honor, a broad park space dedicated to participants in U.S. wars, extends for three blocks on Wisconsin avenue, past the public library and museum. In the heart of the city lies the City centre, a municipal redevelopment area dominated on the west by the massive neoclassical courthouse, made of Indiana limestone, and extending to lake-front Juneau park. Side by side on its north are the municipal auditorium and arena, whose halls can seat 24,500 persons and provide 140,000 sq.ft. for exhibits; on the south the city hall (1894) suggests a Flemish Renaissance town hall. The county's parks and river parkways cover more than 9,100 ac. and provide for all the popular games and recreations, including an extensive zoological garden, botanical gardens and golf courses. County stadium (capacity 43,110) is the home of the Milwaukee Braves, baseball team of the National league.

**History.**—In 1673 Jacques Marquette and Louis Jolliet skirted the west shore of Lake Michigan in their canoes, and Milwaukee bay is distinctly marked on a map attributed to Marquette. La Salle and his party probably stopped there on their way south in 1679, and the name (spelled Melleoiki) first appears in missionary records of that year. Occasional French fur traders may have visited there in the late 17th century. By the time of the American Revolution British traders also were stopping. Jacques Vieau used the Milwaukee post annually for the North West Fur company (British) from 1795 to 1818, when he was superseded by his French-Canadian son-in-law Solomon Juneau (1793–1856), representing Astor's American Fur company. The settlement, sporadically occupied by Indians, was on the route from Fort Dearborn (Chicago) to Green Bay, and as soon as Indian titles in southeastern Wisconsin were extinguished by treaties with the Menomini and others, 1831–33, land seekers appeared. In 1833 Morgan L. Martin (1805–87), a Green Bay land speculator of New York birth, visited Milwaukee, mapped the harbour, and conceived of townsite speculation. In association with Michael Dousman he entered into an agreement with Juneau for a half interest in the latter's pre-emptive claim to the east side. The next year Connecticut-born Byron Kilbourn (1801–70) and a Virginian, George H. Walker (1811–66), planned a similar promotion of the west and south sides. Platting of the townsite occurred in 1835, with completion of the survey and opening of the land to public sale. Two of the villages, officially Milwaukee East Side and Milwaukee West Side, were popularly known as Juneautown and Kilbourntown; rivalry between them, especially over bridges, streets and finances, survived their union as two wards of the town of Milwaukee in 1839 and the addition of Walker's Point (to the south) in 1845. In 1846 the three wards, each of which up to that time had retained complete financial and administrative autonomy of its own affairs, were incorporated as the City of Milwaukee, with Juneau the first mayor.

The first newspaper, the *Milwaukee Advertiser*, began publication on July 14, 1836. In the same year a public school district was formed but a free school system awaited incorporation of the city. In 1839 George Smith and Alexander Mitchell established the Wisconsin Marine and Fire Insurance company, which, despite its name, served as one of the strongest banking houses west of the Alleghenies for over 40 years. The first brewery was built in 1840. Harbour development, advocated as early as 1834, soon permitted Milwaukee's emergence as a major grain and flour port, draining the wheat-raising hinterlands to the Mississippi by plank road and rail. Commerce dominated the city's early decades, but in post-Civil War years industry developed, especially meatpacking, tanning, brewing and iron- and steelmaking.

**Population Characteristics.**—About 1840 the Yankee village received the first German migration; by 1900, 72% of the population had Germanic origins which marked the city's society and culture. Modest Irish and Scandinavian migrations dwindled late in the 19th century before a Polish influx, which impressed the city's south side as much as the Germans on the north. Additional east and south European elements joined a Negro migration from the south in swelling the city's population in the 20th century. An 1850 population of 20,061 reached 285,315 by 1900 and 578,249 by 1930, after which growth was slower.

**Government.**—The city operates under an 1874 charter, providing for a "weak" mayor and a "strong" board of aldermen representing 20 wards and elected every four years. A charter convention of 1908 failed to bring reform but a home rule amendment to the state constitution in 1924 permitted revision by simple council ordinance. Frank P. Zeidler served as mayor from 1948 to 1960, the third member of the Socialist party to become the city's chief executive (Emil Seidel 1910–12, Daniel W. Hoan 1916–40). Henry W. Maier became mayor in 1960.

A Progressive era reform movement brought Milwaukee a reputation for clean and efficient government. Nonpartisan elections (1914), law enforcement free from politics, long tenure for able career administrators and civic support of expanded government services on a pay-as-you-go basis characterized the city. But in the 1960s tension with the 18 suburbs in the county—eight newly incorporated and several sparsely settled—had replaced the provision and maintenance of water supply and sewage disposal facilities and other housekeeping functions as the city's major concern. Programs for an expanded water supply, expressways, public housing, renewal and redevelopment of the city's core, downtown parking and cultural and recreational facilities not only represented municipal maturity but also entailed new relationships to suburban, county, state and federal governments.

**Commerce, Industry and Transportation.**—Milwaukee is

the commercial metropolis of the state and a major industrial centre of the United States in the value of its manufactured products. Its fine harbour, open during most of the year and accessible to the largest ships using the Great Lakes-St. Lawrence seaway, is the most important gateway to the northwest for traffic across Lake Michigan. Water-borne commerce in the second half of the 20th century amounted to 7,500,000 to 9,000,000 tons annually. For more than a century Milwaukee has been one of the great grain ports of the Great Lakes. A small but increasing portion of its port tonnage is overseas. Wholesale trade covers the upper Mississippi valley; retail trade suffers from nearness to Chicago.

The leading manufactured products are electrical machinery, construction and mining machinery, castings and forgings, general industrial machinery and autos and auto parts. Dependence on such capital goods somewhat obscures important consumer products—small gasoline engines, batteries, locks, motorcycles, outboard motors, beers, shoes and meats. The largest firms do not dominate the local economy nor is military buying so important as in other heavy industry centres. Local, and in many instances family, ownership of substantial concerns has persisted longer than was usual in other places. The labour force is highly skilled and well paid.

Several federal highways enter and pass through Milwaukee. Railways connect the city with Chicago and with the Twin cities of Minneapolis and St. Paul, Minn., and with the west; some eastern rail traffic goes by car ferry across Lake Michigan. Milwaukee county's General Mitchell air terminal on the south is a regular stop for commercial airlines; it handles both passengers and freight. The Lawrence J. Timmerman airport to the northwest is for feeder use. Numerous motor coach, truck and lake steamship lines serve the community. Electric and gas buses have superseded trolley cars within the city, while expressways violate a checkerboard street pattern to facilitate auto flow from central city to suburbs.

**Education and Welfare.**—The public school system includes elementary and junior, senior and technical high schools and a vocational school, founded in 1912, which offers apprenticeship; continuation, adult vocational and recreational; and accredited high-school and junior-college programs. There are also Roman Catholic and Lutheran elementary and high schools. The central library services a number of neighbourhood branches and some of the suburbs. The museum of natural and human history has a special collection of prehistoric American Indian materials. Its typewriter collection appropriately reflects the Milwaukee invention of the first practical instrument in 1869 by C. Latham Sholes. The Milwaukee Art centre, housed in the War memorial on the lake front, combines collections of the former Milwaukee Art institute and Layton Art gallery. The Layton School of Art became a degree-granting institution in 1951, the Wisconsin Conservatory in 1930. Marquette university, a Roman Catholic coeducational institution founded in 1864, provides liberal arts, business, engineering, dental, medical, law and journalism curricula. The University of Wisconsin-Milwaukee combines the former facilities of the Milwaukee State (Teachers) college and the University of Wisconsin's Milwaukee extension division, merged in 1956 as an autonomous unit under a provost responsible to the president and regents of the university. It awards degrees in education, letters and science, commerce and engineering. Milwaukee-Downer college, a private college formed in 1895 by consolidation of Milwaukee college and Downer college of Fox Lake, instructs women in liberal arts, home economics and occupational therapy. Alverno (1887), Cardinal Stritch (1937) and Mount Mary (1872) are Roman Catholic colleges for women; St. Francis seminary (1856) prepares Catholic priests; and Concordia college (1881) offers a Lutheran preseminary two-year course. Milwaukee School of Engineering (1903) is internationally known for electrical and mechanical training. In suburban Wauwatosa, county welfare institutions care for the aged, dependent, diseased and insane, while at Wood there is a U.S. veterans administration hospital on the site of one of the nation's three original post-Civil War soldiers homes. Civic programs for public health, traffic safety and fire and crime prevention have brought many records and awards since the 1920s.

The *Milwaukee Sentinel* (morning; founded 1837, daily since 1844) and the *Milwaukee Journal* (evening; founded 1882) are augmented by a German and a Polish daily, the survivors of a once thriving foreign language press, and by numerous church, suburban and foreign language weeklies. Several television stations, one of them an educational outlet of the vocational school, and several radio stations transmit local and network programs to the area. (F. I. O.)

**MILYUKOV, PAVEL NIKOLAEVICH** (1859–1943), Russian historian and liberal leader who became minister of foreign affairs in the first provisional government after the March revolution of 1917, was born in Moscow on Jan. 27 (new style; 15, old style), 1859. He had a distinguished academic career, specializing in Russian history and teaching it at Moscow university. He surpassed his master V. O. Klyuchevski in the comprehensiveness of his vision and soon won a nationwide reputation as a historian. His frank public speaking on contemporary issues, however, led to his imprisonment in 1901, but it also brought him invitations to teach in the United States (1903–04). Milyukov was a convinced westernizer, seeing in absolutism the main obstacle to Russia's progress toward parliamentary democracy. Under the influence of British radical thought he strove to make Russian liberalism a mass movement committed to social reform. Milyukov was a better judge of abstract ideas than of human nature and was too inflexible to be successful in politics.

As a contributor to the clandestine journal *Osvobozhdenie* ("Liberation"), founded in 1902, Milyukov advocated a freely and democratically elected national assembly and did much to swing the incipient liberal movement to the left. In the revolutionary year 1905 he returned to Russia to become the guiding spirit of the Constitutional Democratic, or Kadet, party and editor of its daily newspaper *Rech*. On three occasions in 1905–06 he had private talks with government representatives (S. Y. Witte, D. F. Trepov and P. A. Stolypin); but he refused to compromise on the essentials of the Kadet program, and no agreement resulted.

As the revolutionary tide ebbed Milyukov took a more moderate stand. In the third and fourth dumas (1907–17) he emerged from the wings to become the Kadet party's acknowledged leader. He condemned bureaucratic abuses and championed the rights of non-Russian nationalities within the empire. When World War I broke out he soon adopted a patriotic attitude. He considered that Russia's national interests made the acquisition of the Turkish straits a legitimate war aim, and he advocated the formation of a ministry enjoying public confidence to unite the country in prosecuting the war. This latter demand was unwelcome to reactionaries at court and in the bureaucracy. Milyukov endeavoured to overcome their obstruction by gentle pressure from the duma, in which he organized the moderate parties into a Progressive bloc (Aug. 1915). His overcautious tactics proved ineffective, and in the autumn of 1916 he abruptly changed course. On Nov. 14 he delivered a powerful speech in the duma implying that the government was guilty of treason. His charges had no real substance, but were effective in stimulating revolutionary sentiment. Once again he had miscalculated.

In March 1917 Milyukov sought to preserve the monarchy as a stabilizing influence. But the tide was running strongly against him; and in the provisional government under Prince G. E. Lvov, though intellectually he towered above his colleagues, he was soon outmaneuvered by the Socialist A. F. Kerenski. As foreign minister he clung to the demand for the Turkish straits and stubbornly resisted popular pressure for a democratic peace without territorial annexations. When on May 1 he reluctantly sent to the Allies a note in the sense desired by the Petrograd soviet he deliberately phrased it in ambiguous terms. Disturbances broke out and he had to resign (May 15). He then attempted unsuccessfully to counter the provisional government's swing to the left, which he had himself involuntarily facilitated. After the Bolshevik revolution of Nov. 1917 he served as political adviser to Gen. A. I. Denikin. After emigrating to Paris he reverted to his early radicalism, trying to unify the various currents on a common

republican democratic platform. He remained politically active, as a staunch liberal, until his death at Aix-les-Bains, Fr., on March 31, 1943.

Milyukov's works include *Istoriya vtoroi russkoi revolyutsii* ("History of the Second Russian Revolution"; 2 vol., 1921), *Rossiya na perelome* ("Russia's Great Change"; 2 vol., 1927) and *Outlines of Russian Culture* (3 vol., 1942). His *Vospominaniya* ("Reminiscences," 2 vol.) appeared in New York in 1955.

(J. L. H. K.)

**MILYUTIN, DMITRI ALEKSEEVICH,** COUNT (1816–1912), Russian army officer and statesman, generally regarded as his country's greatest minister of war, was born in Moscow on July 10 (new style; June 28, old style), 1816, of a family of the lesser nobility. After completing his training at the Nicholas military academy in 1836, he served in the Caucasus from 1838 to 1845. Subsequently he was a professor in the Nicholas academy till 1856, when he was appointed chief of staff of the Caucasian army operating against Shamil. During his years at the academy he had published a series of military studies: the best known of these, *Istoriia voiny Rossii s Frantsii*, five volumes (1852–53), dealt with A. V. Suvorov's campaign of 1799. In 1860 he entered the war ministry as deputy minister and in Nov. 1861 became minister of war, a position he held for 20 years. Milyutin inaugurated a series of radical reforms throughout the entire Russian military system. He greatly modified the code of harsh discipline and brutal punishments; he improved the military education of both officers and regular troops; and he reorganized and strengthened the administration of the army. The period of regular service was reduced and, most important of all, he introduced universal military service through the statute of 1874. Henceforth all young men reaching the age of 20 were liable to six years of active service and nine in the reserve. These measures were part of the great reforms of the emperor Alexander II's reign. Milyutin was made a count in 1878.

After the congress of Berlin (1878) Milyutin was a proponent of the League of the Three Emperors linking Russia, Austria-Hungary and Germany. He retired in 1881 when his policies came into conflict with those of the new emperor, Alexander III. He died at Yalta on Feb. 7 (N.S.; Jan. 25, O.S.), 1912. His diaries were published in Moscow in 1947–50. (B. J.)

**MILYUTIN, NIKOLAI ALEKSEEVICH** (1818–1872), Russian statesman remembered for his role in the emancipation of the serfs under the emperor Alexander II, was born in Moscow on June 18 (new style; 6, old style), 1818, the younger brother of D. A. Milyutin.

Educated at Moscow university, he entered the ministry of the interior at the age of 17 and advanced rapidly in the service. He was responsible for the reform of the administration of St. Petersburg, Moscow and Odessa, to which he imparted elements of self-government, and was in charge of the preparation of statistical manuals bearing on social and economic developments. In 1856 he became identified with the preparatory work for the emancipation of the serfs.

His program of reform was deemed too liberal by powerful reactionary circles, but he had influential supporters, among them the grand duchess Elena Pavlovna, widow of the late emperor Nicholas I's brother Michael. Appointed assistant minister of the interior in 1859, Milyutin took a leading part in the framing of the emancipation acts of March 3 (N.S.; Feb. 19, O.S.), 1861, from which he succeeded in eliminating some of the more objectionable features advocated by the ultraconservative groups. He was forced to retire in April 1861, but after the Polish insurrection of 1863 he was appointed secretary of state for the Russian part of Poland, where in 1864 he carried out a land reform favouring the peasantry at the expense of the Polish landowners, who were considered as the core of Polish nationalism. Milyutin was also instrumental in the russification of the Polish schools and administration and in the abrogation (1866) of the concordat with the Holy See. He suffered a stroke in 1866 and died in Moscow on Feb. 7 (N.S.; Jan. 26, O.S.), 1872.

**MIME,** a dramatic-literary form of Greek and Roman origins. The word is derived from the Greek *mimeisthai* ("to imitate or represent") and refers to both the play and the actor. The Greco-Roman mime was a farce that stressed mimetic action. The preliterary form can only be guessed at, and even the surviving fragments of the playlets of Epicharmus (*q.v.*), a 5th century B.C. writer of comedies, yield only the scanty information that the mimes to which he had given literary stature were concerned with scenes of daily life or with mythological travesty. Other Greek writers of mimes were Sophron (fl. *c.* 430 B.C.) and Herodas (3rd century B.C.) (*qq.v.*).

It can hardly be assumed that early Italian life was deprived of mimetic performances. The existence of a native Italian form of mime may safely be postulated; the Latin word *planipes*, "with bare feet," points to a mime actor who wore no shoes in performance. The first to give literary form to the Roman mime was the knight Decimus Laberius (*c.* 105–43 B.C.) (*q.v.*), who was eclipsed by the ex-slave Publilius Syrus (*q.v.*). The presentation of mimes was a traditional feature of the annual *Floralia* festival, which, being licentious in spirit, opened the popular stage to naked mime actresses (*see* FLORA).

Though only fragments exist, it is clear that the usual mime plot, while free to indulge in biting topical allusion, centred principally around scenes of adultery and other vice. Evidence exists that acts of adultery were actually performed on the mime stage during the Roman empire. Execution scenes with convicted criminals in place of actors are on record. When condemning the Roman theatre, the early Christian writers attacked primarily the mimes in this state of degeneracy. Stock characters and situations of the classical mime found their way into the comic drama of Plautus and Terence and reappeared greatly modified in the *commedia dell'arte* (*q.v.*), a Renaissance extempore entertainment with roots in the Roman theatrical tradition.

Modern mime developed into a purely silent art whereby meanings are conveyed solely through gesture, movement and expression. Its influence was felt strongly in ballet, where the formal posturing of classic style modulated into the descriptive silence of modern dramatic dance movement. In the United States, silent film mimes like Charles Chaplin and Ben Turpin, television entertainers like Sid Caesar and circus clowns like Emmett Kelley were masters in the ancient tradition. The high art of modern mime, however, was templed in France, where its practice was ennobled philosophically by Étienne Decroux, Jean Louis Barrault and Marcel Marceau. Marceau defined mime as "the art of expressing feelings by attitudes and not a means of expressing words through gestures."

**MIMETITE,** a mineral consisting of lead chloroarsenate and closely resembling the lead chlorophosphate pyromorphite (*q.v.*) in appearance and general characters. The arsenic in mimetite is usually partly replaced by equivalent amounts of phosphorus; thus, there may be a gradual passage from mimetite to the isomorphous pyromorphite. The two species can, as a rule, only be distinguished by chemical analysis and because of their close resemblance, the less frequently occurring chloroarsenate was named mimetite or mimetesite, from the Greek word for imitator. Like pyromorphite, mimetite is found in the upper parts of veins of lead ore, where it has been formed by the oxidation of galena and mispickel (arsenopyrite). When found in large amount it is important as an ore of lead. Its composition can be represented by the formula $Pb_5(AsO_4)_3Cl$ and it crystallizes in the hexagonal system. Crystals of pyromorphite though usually optically uniaxial are sometimes biaxial, but in mimetite this anomalous character is almost always present; a cross section of a hexagonal prism of mimetite shows a division into six optically biaxial sectors or a complex lamellated structure. Mimetite is usually yellow or brown, rarely white or colourless; the lustre is resinous to adamantine. The hardness is

3.5, the specific gravity, 7.0–7.25. The best-crystallized specimens are those from Johanngeorgenstadt in Saxony, Wheal Unity in Cornwall, and Tsumeb in South-West Africa. In the United States mimetite has been found in Pennsylvania and in Arizona, California, Nevada and Utah. It was formerly found in considerable amount at Drygill, Cumberland, as six-sided, barrel-shaped crystals of a brownish-red or orange-yellow colour; this variety has been called campylite from a Greek word meaning curved, because of the remarkable curvature of the faces of the crystals.

**MIMICRY,** as used by naturalists, refers to certain advantageous resemblances chiefly between animals or, in a few cases, between plants (e.g. the common dead-nettle and the stinging nettle). These resemblances may exist between species of very different degrees of relationship, generally distant but sometimes near; they are such as appeal to the senses of enemies, especially to the sense of sight, not uncommonly to hearing and occasionally to smell and touch. They differ from the much larger class of protective resemblances that bring about concealment by a likeness to some object of no interest to enemies. The true mimic resembles a conspicuous "model" that is feared or disliked by its enemies; thus the mimic gains protection.

Mimetic resemblances also differ from similarities that are an incidental result of similar functions, such as the general likeness in form between the race horse and the greyhound or between the true moles and the molelike species among the rodents and marsupials. Moreover, the incidental likeness between species that resembles a common part of their surroundings—sand, bark, leaves, etc.—is not considered mimicry. The emphasis has been on the study of animal mimics rather than of plant mimics, a stress that will be followed in this article.

## ORIGIN AND EXTENT OF MIMICRY

Several views as to the origin of mimetic resemblances are that they are due: (1) to the direct influence of the environment acting similarly on different species; (2) to a physiological response to constant mental experience such as colour sensation; (3) to sexual selection, modified by the presence of other types of colour (this suggestion, attributed to Fritz Müller, is weakened by the fact that female butterflies are far more commonly mimetic than males); (4) to the same gene and its mutation in mimic and model; and (5) to a restricted range of possible animal colour patterns and shapes, so that the mutation of different genes, having different effects, will sometimes bring about approximately the same appearance in distinct species.

These resemblances are no mere coincidence, for they are geographically linked. Mimics are found in the same localities as their models and when the latter are modified, the mimics change with them. There are exceptions when the mimics are greater wanderers than their models, and in one remarkable example two butterflies in western China appear to be mimics of a model very common south of the Himalayas; in this case selection by migratory insectivorous birds may be influenced by their remembered experiences of the tropics.

Although mimetic resemblance is believed to exist in mammals, birds and fishes, the number of examples is small and their interpretation often doubtful. Among reptiles, poisonous snakes are mimicked by harmless species. Even the English grass snake will often, when cornered, poise itself and strike like an adder.

But, for the study of mimicry, the insects are supreme: small proportions survive and generations swiftly follow one another, so that the results of natural selection are evident in a short time.

The most formidable of all models are the bees and wasps, striking examples of which are the carpenter bees (Xylocopidae) and their fly mimics. Mimicry and protective resemblance is also found in the Homoptera which, in addition to the cicadas, aphids and others, include also the Membracidae, a cosmopolitan family of small insects with a concentration in tropical America. They have on the body ring behind the head a projection which grows backward and expands into a shield covering every part except the head, wings and legs. This is so marked as to represent protected insects and other natural objects. Certain groups of butterflies that are particularly rich in examples of mimicry have long been studied.

### BUTTERFLY MODELS AND MIMICS

Much about mimicry in butterflies is meaningful only in the light of natural selection and consistent with the view that it is an advantageous resemblance and has been developed for its own sake. The butterflies most generally mimicked by species of other groups and by day-flying moths belong to a few predominant tropical subfamilies, many of whose members are unpalatable to prey, the Danainae, Acraeinae and the genus *Atrophaneura* of the Papilioninae in the old world, and, in the new, the Ithomiinae allied to the first, and the Heliconiinae allied to the second, together with very few Danainae and many Acraeinae. Now, however widely the types of pattern vary within each of these subfamilies, they are still mimicked by butterflies of other groups and often by moths. The South American acraeines have very different patterns from those of the African acraeines, yet both are extensively mimicked.

**Danaine Butterflies.**—The most striking evidence, however, is supplied by the divergent colours and patterns of the danaine models, of which a few examples are figured. The oriental *Hestia* and its allies are large, black-and-white butterflies with thin, papery wings. A characteristic example is *Hestia lenconoe* from the Philippine Islands and its swallowtail mimic (*Papilio idaeoides*) from the same locality. In the same part of the Malay peninsula the male of *Euploea midamus*, an example of a far commoner and widespread danaine type, that of the blue *Euploeas*, mimics another swallowtail (*Papilio paradoxus*). In Africa the danaines, though far fewer, are the chief models for mimicry. Most of the species belong to the genus *Amauris*, black butterflies with white or yellowish markings, very unlike the oriental Danainae.

An entirely different type of danaine pattern is borne by a series of nearly related species in the oriental region, probably the original home of the group. One of those bearing the pattern has migrated westward and become the chief model for mimicry in Africa, while two others have traveled eastward and become the ancestors of American species mimicked by indigenous American butterflies. The best-known invader, the monarch (*Danaus plexippus*), is mimicked by a nymphaline butterfly, the viceroy (*Limenitis archippus*). The viceroy is closely related to the British white admiral and is itself so recently descended from a North American white admiral that the two will interbreed and produce hybrid offspring. In all the earlier stages of its life history the mimic remains a white admiral, the mimetic resemblance being restricted to the final colour and pattern. If mimetic likeness were the result of local influences, the invader would have come to resemble the native rather than that the native should mimic the invader. This is clearly not so in certain butterflies with many forms of female. Thus, three Uganda females of the African swallowtail *Papilio dardanus* mimic, respectively, three very different danaine patterns, and the fourth an acraeine; in other parts of Africa where the danaine patterns alter, and one of them or the acraeine model is absent, the corresponding female is similarly modified or wanting. In another African swallowtail, *Papilio cynorta*, the females mimic an acraeine, changing geographically with the changes of the model. But in Ethiopia, where there is no appropriate model of this group, the female mimics a danaine.

In butterflies the female is the more commonly mimetic. When both sexes mimic, the female's likeness to a model is often the more complete, perhaps because she needs special protection while laying eggs, when she is especially vulnerable to sudden attack and unable to escape by speed. Sight also plays some part in sexual stimulation in butterflies, so that a common male pattern helps to preserve the species—indeed, male butterflies are polymorphic much less often than are the females, quite apart from mimicry.

**Atypical Mimicry.**—The species of the great tropical groups of largely unpalatable butterflies are not only mimicked by butterflies of other families but also mimic each other. Thus, several African acraeines mimic danaines, while in both groups the species of one genus sometimes mimic those of another; the same is true of the oriental danaines. In tropical America the few danaines and many of the heliconines mimic species of an abundant group, the ithomiines. This last mimetic association has caused much confusion, for the superficial resemblance between the ithomiines and an important section of the heliconines is so strong that both

groups were united under the family Heliconiidae by the older naturalists. But their true relationship is now recognized and the two sections are placed far apart, the Ithomiinae next to the Danainae and the Heliconiinae next to the Acraeinae. In the many mimetic associations between the two groups, the Ithomiinae, with rare exceptions, are the models, the Heliconiinae the mimics.

## BATESIAN AND MÜLLERIAN MIMICRY

**Definition.**—It is obvious that the resemblance between the butterflies of distasteful groups is, as H. W. Bates recognized, a different thing from mimicry as he defined it: the likeness of a harmless or palatable species to a formidable or nauseous one that advertises its qualities by warning characters, especially colours, but often by movement, attitude or sound. The mimic gains advantage by the display of false warning characters. This is called Batesian mimicry after its discoverer. The resemblance between the distasteful species themselves was explained later by Müller as an adaptation that economizes life: if two distasteful species are alike, they will share between them the lives collectively lost before the enemies have learned to associate the warning characters with their special means of defense. If they are unlike, the lives must be contributed by each of them independently. These resemblances, a form of common or combined warning, are called Müllerian mimicry. A Batesian mimic may be compared to an unscrupulous merchant who copies the advertisement of a successful firm. Müllerian mimicry may be thought of as a union of firms to adopt a common advertisement and share the expense.

**Relative Efficiency.**—The qualities of Müllerian mimics differ widely in effectiveness, and the species differ immensely in their relative numbers and in their capacities for variation. Hence, models and mimics exist among them no less than in Batesian mimicry and in both there is the same evidence of the development of a mimetic from a different nonmimetic appearance still retained by allied species and often by the nonmimetic male. But while Batesian mimicry is never an advantage, and may be a disadvantage, to its model, Müllerian mimicry is never a disadvantage to the model. This criterion, though simple, is difficult to apply because of our imperfect knowledge of mimics and their enemies. More or less conclusive, indirect evidence is therefore often adduced, and opinions differ widely as to the relative importance of the two kinds of mimicry.

The resemblance of a Batesian mimic to its model is closely related to protective resemblance. In fact, Bates originally included both resemblances under mimicry. A. R. Wallace and nearly all later writers on the subject have differed with Bates in this, because although the two classes are so near akin, the species in one are conspicuous, in the other well concealed. They may, however, be conveniently grouped together under deceptive (or apatetic) resemblance. Both classes include palatable species, much sought after by the enemies of the group to which they belong. Any evidence supporting the conclusion that a mimic has been developed from a species with concealing colours would be evidence that it is a Batesian and not a Müllerian mimic. Such evidence may be obtained by comparison with its closest nonmimetic allies, and in butterflies often by comparing a mimetic female with its nonmimetic male, noting especially the undersurface, where concealing colours are particularly developed. In the tropical American butterfly *Protogonius*, conspicuously mimetic on the upper surface and dead-leaflike on the under, Kaye has noted that the wing is so transparent that when the insect is sailing with expanded wings above the observer, he can see the colours of the upper side only.

## ADAPTIVE VALUE OF MIMICRY

**Avoidance by Predators.**—The mimics score an advantage because they are avoided by predators that mistake them for species of unpleasant taste or smell. In butterflies the models usually exhibit warning coloration. This is easily learned and remembered by birds, for it involves patterns of a simple and conspicuous kind. These are usually the same on the upper and under surfaces of the wings, so that they can be recognized from whatever point of view the insects exhibiting them are seen, in flight or even when they are resting with the wings closed. Such species fly slowly, displaying themselves in a way that would make them easy prey, and, in fact, they may be attacked by young birds that have not yet learned to associate a particular butterfly pattern with unpalatability. Although these butterflies may be pecked at, they do not suffer permanent damage because their bodies are soft and flexible, unlike the bodies of most other insects, including their mimics.

Though it has long been believed that these distasteful models are avoided by insect-eating birds, there was little experimental evidence to support this contention until L. and J. Brower reported their studies on approximately 3,000 butterflies. Using North American species, they chose as models the monarch, a danaine, and the pipevine swallowtail (*Battus philenor*), a black and blue form belonging to the Polydorus group of the Papilionidae. The scrub jay (*Cyanocitta coerulescens*) was used as a predator. The birds found the monarch invariably unpalatable and never ate one. When a jay occasionally pecked at a specimen, it would drop the monarch, wipe its beak vigorously on its perch, ruffle its feathers and shake itself—a series of reactions that the mere sight of the butterfly would subsequently initiate. Having learned to avoid the monarch, the birds were then offered its mimic, the viceroy. This butterfly was palatable to those jays that had no experience of the monarch, but was avoided by those that had. Indeed, the birds reacted to the sight of a viceroy in the same way as to a monarch, by wiping the bill and shaking the feathers. Clearly, therefore, the mimicry was effective in this association. So, too, it was when the pipevine swallowtail was the model used. This species was regarded as extremely distasteful by the birds, and they subsequently reacted to its palatable mimic, the spice-bush swallowtail (*Papilio troilus*), as if it were distasteful too, though one out of the three birds used showed some capacity to distinguish it. To jays that had not discovered the distasteful qualities of *Battus philenor*, *P. troilus* was highly palatable.

**Ratio of Mimics to Models.**—The Browers also studied the numerical proportions of model to mimic that were needed for effective mimicry. Working in England, they used the starling (*Sturnus vulgaris*) as a predator and the yellow mealworm (*Tenebrio molitor*) as prey. These mealworms are normally eaten with great avidity by the starlings. Artificial "models" were produced by making the mealworms conspicuous and distasteful by giving them warning coloration, consisting of a striking band of green cellulose paint, and dipping them into a strong solution of quinine. The mealworms were similarly banded to produce "mimics," but these were dipped only into distilled water. The starlings were given different proportions of models and mimics, which were presented in a random order. With the mimics 10%, 30% and 60% of the total, most of them (80% or more) escaped being eaten. Even when the mimics were nine times commoner than the models, 17% of them were refused. The uneaten ones were those encountered immediately after the birds' unpleasant experience in tasting quinine, showing that the escape of the mimic was related to the distasteful flavour of the model. As the Browers remark, "mimicry can operate to a significant extent under conditions which have long been incorrectly assumed to give no advantage to the mimic." As a control, before or after each model or mimic was offered, an orange-banded (i.e. nonmimetic) mealworm dipped into distilled water was offered to the birds, and this was always eaten. So, too, were the green-banded "mimics" when given to birds that had no experience of specimens dipped in quinine; thus, cellulose paint on the mealworm did not make it less palatable.

**Occurrence of Predation.**—The criticism that birds seldom attack butterflies often is made by those who judge the situation in temperate regions and have not seen the immensely more crowded life and stringent competition of tropical forests. It is there that mimicry is so widespread and there, too, that the intense contrasts of light and shade favour so much the earlier stages of the resemblance. Mimicry occurs both in temperate latitudes and in open country, but it is much less common there. The frequent occurrence of beak marks on the wings of butterflies is indirect evidence of the attacks by birds. It may be the print of the beak on the wing surface or a V-shaped tear from the margin, often identical on two corresponding wings. An observed attack of a bird on a butterfly produced just such damage. Marks also occur

An example of Batesian mimicry: the monarch butterfly (left), subfamily Danainae, a distasteful species, is mimicked by the viceroy (right), subfamily Nymphalinae, a palatable species

An otherwise defenseless fly, family Bombyliidae, is protected by its resemblance to the honeybee

A Peruvian net-winged beetle (above) and its mimic, a beetlelike moth (below)

The stingerless bumblebee moth (above) is avoided by birds because of its resemblance to the true bumblebee (below)

## MODELS AND THEIR MIMICS

when a distasteful species with warning colours has been attacked and subsequently released because it was found inedible.

H. B. D. Kettlewell's work on industrial melanism (*see* MELANISM), though carried out on cryptically-coloured moths resting upon tree trunks, is important here because it shows how easily some aspects of bird predation may be overlooked. Ornithologists and entomologists were agreed that birds seldom or never selectively prey upon resting moths. Kettlewell has shown that many species of birds readily prey upon those resting moths that contrast with their backgrounds. This was earlier overlooked, for the act of predation takes place in a flash and requires carefully planned experiments to detect it, even though it is so frequent. It is likely, therefore, that the selective elimination of flying or resting butterflies, especially in tropical forests, has similarly been minimized.

As a Batesian mimic increases in numbers relative to its model, so the advantage of its mimicry wanes. Finally, it becomes a disadvantage when predators begin to link a given conspicuous pattern with something edible rather than inedible. It may be desirable, therefore, for the same species to copy several distinct models. Some Batesian mimics exhibit polymorphism (the occurrence of different forms of a species). The mimetic phases must be clear-cut, since an appearance intermediate between that of different models would provide no protection. Not only may these exist together in the same region but they may be replaced by others elsewhere. In addition, mimics must correspond with the various races of their models found from one part of their range to another. Moreover, a nonmimetic form of a butterfly may persist quite commonly with the mimetic ones. It does so because the various polymorphic phases of a species in the same habitat will be adjusted in frequency by natural selection until all receive equal protection. On the other hand, polymorphism is not to be expected among Müllerian mimics, since these aim at uniformity.

## GENETIC BASIS OF MIMICRY

**Theories.**—As is usual with polymorphism, the switch-reaction converting one to another clearly distinguishable mimetic (or nonmimetic) form is genetically controlled by a single-factor difference giving sharp segregation (*see* GENETICS). Different states of the same gene (allelomorphs) arise suddenly, though very rarely, by mutation. Therefore, it has been suggested in the past that the distinct mimics controlled by genes also arose suddenly, that they appeared, with all their marvelous adaptations, complete and fortuitously, without evolutionary adjustment. This is quite incredible. Mimicry involves accurate resemblances of different features, such as colour, pattern and sometimes shape; such multiple adaptations are known in many species.

A much sounder solution is provided by a theory given by R. A. Fisher and developed later. A mutant arises by chance; if it gives some slight resemblance to a model, its effects later can be improved gradually by natural selection acting on the total gene-complex. Although the switch-genes controlling polymorphic mimics arose suddenly, their effects did not immediately produce a full-blown mimic. On the contrary, a slow evolutionary process is required for the perfection of a mimic. This view is supported by the existence of mimetic species whose models are very rare. Here the resemblances accurate elsewhere break down, as with the African *Papilio dardanus* in the mountains near Nairobi.

**Experimental Support.**—C. A. Clarke and P. M. Sheppard used *P. dardanus* to put the evolution of mimicry on a sound basis. They succeeded in breeding this species, primarily a citrus feeder from Africa, in great numbers in England. By hand-pairing, they reared successive generations from known parents and crossed the different races and subspecies so as to obtain a fairly complete picture of the evolutionary genetics of the mimetic forms.

*P. dardanus* belongs to one of the palatable genera of swallow-tail butterflies, as opposed to the poisonous Polydorus group that does not occur in continental Africa. The males are tailed and are yellow with black markings. Only the females are mimetic. Except in Ethiopia and the adjacent regions, they have lost the tails to resemble their tailless models. A number of the mimetic forms are known, several flying in the same locality, and they are astonishingly dissimilar from one another and from the males, while they resemble their respective models very accurately. Yet, they may segregate together in the same brood, normally preserving their distinctions without the occurrence of intermediates. In the wild, they vary in proportion from one region to another depending on the abundance of their models.

Clarke and Sheppard showed that these mimics are controlled genetically on a unifactorial basis (i.e., by a single gene). The mimic form *hippocoides* is recessive to the others (e.g., *cenea*), their respective models are *Amauris niavius* and *A. echeria*. These models are Danaidae, as are the majority of those copied by *P. dardanus*, but one of its forms, *planemoides*, mimics *Bematistes poggei*, a butterfly of an entirely different family, the Acraeidae. A few of the rare forms of *P. dardanus* are due to a combination, as heterozygotes, of the genes of two of the dominant mimics.

Clarke and Sheppard also obtained specimens from Madagascar, where all the females are malelike; they are tailed, therefore, and nonmimetic. They were able to cross these with the mimetic races from the mainland; when they did so, the similarity of the different forms segregating among the offspring broke down, though each of these was unifactorial. This result supports the statement made earlier that the mimicry did not arise complete with the mutation of the controlling genes.

R. Goldschmidt considered the well-known situation in which a mimic adjusts to the different races of its models. His argument assumes that for biochemical reasons distinct genes may produce an apparent similarity of effect in different species. He therefore expects that the differences between geographic races of mimics (and models) will be of a multiple allelic character involving the locus (position of a gene on the chromosome) controlling the mimetic pattern. Clarke and Sheppard's findings contradict this view: *Amauris niavius* is recognizably different in western and eastern Africa and the forms of *P. dardanus* that copy it are modified correspondingly; these they were able to cross and show that the distinction between them is multifactorial, not allelic. The similarity of mimic and model is not chemical but wholly superficial of appearance and no more; corresponding colours in mimic and model are produced by chemically distinct pigments.

A good example of a mimetic resemblance attained in many ways occurs in the large tropical American association of diverse butterflies and day-flying moths that have developed transparent areas on their wings in mimicry of dominant ithomiine models. Transparency has been produced by the following different alterations of scales in different mimetic species or groups of species: (1) they may be so reduced in size that the light passes between them; (2) they may remain the same size but become much fewer; (3) they may stand up on edge, thus allowing more light to pass; (4) they may remain in the usual overlapping position but become themselves transparent. Furthermore, in the models themselves, the scales of the transparent parts have become minute vestiges, reduced much more in one of the two genera to which the species belong. The wings of many moths that mimic bees are, on emergence from the chrysalis, covered with loosely attached scales that are blown off during the first flight. That there are among different groups such diverse means of attaining the same end is further evidence that natural selection produces these variations.

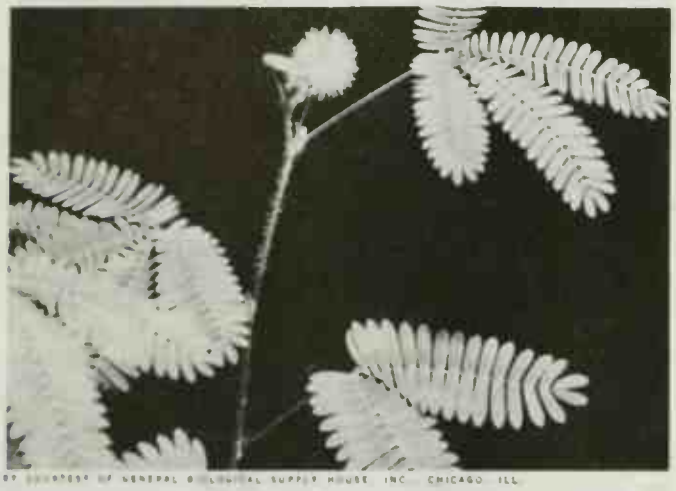
**MIMNERMUS** (fl. *c.* 630 B.C.) of Colophon, early Greek elegiac poet. One of his extant fragments refers to the struggle of the Ionians against Lydia. His most important poems were a set of elegies addressed to a flute player named Nanno. Quota-

tions in later writers show that mythological narratives figured largely in these poems; but Propertius' remark *plus in amore valet Mimnermi versus Homero* (I, ix, 11) seems to suggest that the erotic element was yet more important than the mythological. He took a gloomy view of the onset of old age and prayed for death at 60, for which the more optimistic Solon sternly reproved him.

*See* edition by T. Bergk, *Poetae lyrici Graeci*, vol. 2 (1915); *see* also C. M. Bowra, *Early Greek Elegists* (1938). (JN. A. D.)

**MIMOSA,** so named from the movements of the leaves in those species that "mimic" animal sensibility, a genus of 400 species of the pea family (Leguminosae; *q.v.*), which gives its name to the large subfamily Mimosoideae (characterized by usu-



SENSITIVE PLANT (MIMOSA PUDICA)

ally small regular flowers with valvate corolla), to which belongs the nearly allied genus *Acacia* (*q.v.*). They are distributed throughout almost all tropical and subtropical regions, the acacias preponderating in Australia and the true mimosas in America. The acacias are of considerable importance as sources of timber, gum and tannin, but the mimosas are of much less economic value, though a few, like the talh (*M. ferruginea*) of Arabia and central Africa, are important trees. Most are herbs or undershrubs, but some South American species are tall woody climbers. They are often prickly. The roots of some Brazilian species are poisonous, and those of *M. pudica* have irritating properties. The mimosas, however, owe their interest and their extensive cultivation partly to the beauty of their usually bipinnate foliage, but still more to the remarkable development in some species of the sleep movements manifested to some extent by most of the pinnate Leguminosae, as well as many other (especially seedling) plants.

In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli (*see* TROPISM; PLANTS AND PLANT SCIENCE: *Plant Movements*). When stimulated—say, at the axis of one of the secondary petioles—the leaflets move upward on each side until they meet, the movement being propagated centripetally. It may then be communicated to the leaflets of the other secondary petioles, which close (the petioles, too, converging), and thence to the main petiole, which sinks rapidly downward toward the stem, the bending taking place at the pulvinus (swollen base of the leafstalk). When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued they soon cease to respond to the shock. The common sensitive plant of hothouses, called also humble plant, is *M. pudica*, a purple-flowered native of tropical America, now naturalized in corresponding latitudes of Asia and Africa, but the hardly distinguishable *M. sensitiva* and others are also cultivated. Species of the closely allied genus *Schrankia* are known as sensitive brier in the southern United States.

**MIMULUS,** the generic name for monkey flowers, comprising about 115 species of showy, hardy or half-hardy, herbaceous, rarely shrubby plants of the figwort family (Scrophulariaceae). They are natives of the extratropical or mountainous parts of both old and new worlds excepting Europe, but are most numerous in western North America, 45 species occurring in California.

The plants have opposite, undivided leaves, and axillary, generally solitary flowers with a two-lipped, gaping corolla. The herbaceous species thrive best in damp situations; the shrubby species, of which *M. aurantiacus* (bush-monkey flower), is best known, are adapted for pot culture in the greenhouse. *M. guttatus* (common monkey flower), widespread in western North America, has become naturalized by riversides in many parts of Britain. *M. moschatus* (musk plant), a native of northwestern America, with small, nearly regular, yellow flowers, diffuse hairy stem and hairy scented leaves, is a well known and favourite perennial for pot culture and outside borders. Several other species are cultivated for their attractive flowers.

**MINAHASA** (MINAHASSAN, MINAHASSEN) are a proto-Malayan people of the northern Celebes. They are often called Menadonese from their principal port and city. Today most of the 500,000 Minahasa are Christian, but early accounts depict them as headhunters who also practised human sacrifice. A highly developed form of spiritualism was associated with mediums, the idea of multiple souls, soul catching, the cutting of the umbilical cord with a bamboo knife, tooth filing, bridewealth (*q.v.*) and other traits that are widespread among the pagan tribes of Malaysia. Like the Batak of Sumatra and the people of Nias they had a highly developed megalithic cult, and Minahasa country is dotted with great stone tombs and burial urns. House fronts also present some of the remarkable carvings and paintings which characterized this people when they were pagan.

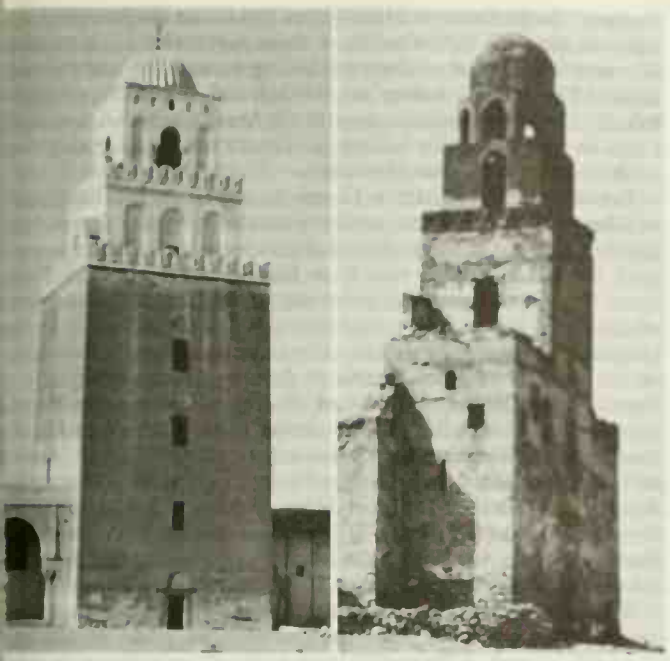
R. Kennedy links the Minahasa with the nearby Gorontalo, a people who practise a form of head flattening similar to that found in Borneo. Linguists have called attention to similarities of the language to those of the southern Philippines, but in general their closest relationships, both ancient and modern, appear to be in Indonesia. Survivals from pagan times have been noted; the modern dress of men and women approximates that of Java, as do most elements of material culture. Viewed against their pagan background this people presents an interesting study in acculturation. *See* also CELEBES.

*See* R. Kennedy, *Bibliography of Indonesian Peoples and Cultures* (1962); W. A. Kaudern, *Ethnographical Studies in Celebes*, 5 vol. (1925–38). (F.-C. CE.)

**MINAMOTO YORITOMO** (1147–1199), one of the most influential shōguns in Japanese history. At a time when the power of the imperial court was declining in the face of continual usurpation by local military lords, he brought order out of the near chaos and gave the country a new form of government which for a century and a half provided a high degree of public order and a considerable degree of humane justice. Yoritomo was himself a member of the military class whose depredations were depriving the imperial government of power. He succeeded in building a large armed following in eastern Japan, and in the late 12th century fought a series of bloody wars with the Taira family, then the dominant military faction in the country. The heroic and gory events of these wars are recounted in Japanese history and legend. Yoritomo was less a field general than a brilliant planner and coordinator; his younger brother and a cousin led his troops in the field most of the time. Upon their complete victory over the Taira in 1185, Yoritomo's forces were the only power in the country capable of bringing peace and orderly government. Instead of making himself emperor, however, Yoritomo was content to rule as shōgun, or the highest military commander of the imperial court. At Kamakura in eastern Japan he established a headquarters for his armed vassals, who were distributed throughout the country to keep order, collect taxes and administer justice. He died in 1199 as the result of a fall from a horse.

*See* also JAPAN: *History*. (T. C. SH.)

**MINARET,** the tower from which the call to prayer is given for Muslims five times a day. In the time of Mohammed no such thing as a minaret was known; when he and his followers first came to Medina they prayed without any preliminary call to prayer. But, having heard that the Jews used a horn and the Christians a *naqus* or clapper, they wanted an equivalent. Mohammed there-



BY COURTESY OF KEPPEL CRESWELL

(LEFT) MINARET OF THE MOSQUE AT KAIROUAN, TUNISIA. (RIGHT) MINARET OF THE MOSQUE OF AL-GUYUSHI (1085), CAIRO, U.A.R.-EGYPT

fore ordered Bilal to give the call to prayer from the highest roof ear the mosque.

The first minarets in Islam were the four square towers at the corners of the *temenos* or sacred enclosure of the pagan god (perhaps Hadad), who was worshiped at Damascus. This *temenos* was the enclosure which is now the Great Omayyad mosque. Ibn al-Faqih (903) refers to these towers, saying, "The minarets which are in the Damascus Mosque were originally watch towers in the Greek days." Al-Masudi (943) says, "Then came Christianity and it [the *temenos*] became a church, then came Islam and it became a mosque . . . and the *Sawami'* [the four corner towers] were not changed; they serve for the call to prayer at the present day." A square tower became the Syrian type of minaret and remained so until after 1200.

In north Africa the oldest minaret, that of Kairouan, is likewise a square tower with a small second story set back upon it; the third story is later. This became the regular type in north Africa and Spain; *e.g.*, at Córdoba, in the mosque of Hassan at Rabat, the Koutoubiya at Marrakech and the Giralda at Seville, the last three dating from the end of the 12th century.

In Iran and central Asia the earliest minarets preserved date from the end of the 11th century. They are all tall, cylindrical, tapering shafts with a gallery near the top, and are often decorated with geometrical patterns in the brickwork, or with faience (*see* A. U. Pope, *Survey of Persian Art*, plates 358–364). They are sometimes built in pairs, generally flanking a monumental entrance, or placed at opposite ends of the main façade; *e.g.*, at Tabriz. Turkish minarets are derived from this type, but they generally have two or even three galleries, and terminate in a tall tapering lead-covered cone. Turkish mosques usually have at least two, sometimes four and, in one case, six minarets (Sultan Ahmed, 1615). Of existing Egyptian minarets, the earliest are those of the mosque of al-Hakim (1013), of which one is a tall, cylindrical stone shaft on a nearly cubical base, the other minaret is a tall, square shaft surmounted by a series of receding octagonal stories. In both cases the original top part is gone. The minaret of al-Guyushi (1085) consists of a square shaft of brick with a stalactite cornice, surmounted by a little cube, an octagonal drum and a dome.

In subsequent minarets this upper part was elaborately decorated, and elongated at the expense of the square shaft, until a type evolved consisting of a square shaft surmounted by an octagonal and a circular story; examples are those of Sangar al-Gawli (1303) and Kusun (1336). After Kusun, the square shaft suddenly shortens so much that only its beveled top corners show above the roof of the mosque, and the visible part consists of a tall octagonal shaft, which has two galleries and terminates in an open domed pavilion; *e.g.*, Shaikhun (1355), Sarghitmush (1358) and Sultan Hasan (1362). *See* also INDIAN ARCHITECTURE; ISLAMIC ARCHITECTURE; MOSQUE.

(K. A. C. C.)

**MINAS,** capital of the department of Lavalleja in southeast Uruguay, was founded in 1753 and named for the surrounding mines (Spanish *minas*). In the second part of the 20th century Minas became increasingly attractive to tourists, since it is only 75 mi. from Montevideo and offers hills and forests, both unusual in Uruguay. Its bottled mineral waters long have been distributed throughout the country. A brewery also uses Minas' famous water. Neighbouring mines and quarries, administration, trade and some industry provide the city's principal occupations. Minas is on a national highway and railroad line. Its population (1962 est.) was 39,005. (M. I. V.)

**MINAS DE RÍOTINTO:** *see* RÍOTINTO.

**MINAS GERAIS** (*i.e.*, "general mines"), an inland state in Brazil. Area 225,192 sq mi. Pop. (1960) 9,798,850. Among the Brazilian states it is exceeded in population only by São Paulo. Minas Gerais, formerly spelled Geraes, is bordered by the state of Rio de Janeiro on the southeast, by the state of São Paulo on the south and west, by Goiás on the northwest, by Bahia on the north and by Espirito Santo on the east. An area of 3,614 sq mi. along its eastern border is claimed by both Minas Gerais and Espirito Santo. The state capital is Belo Horizonte (q.v.).

**Physical Geography.**—Minas Gerais lies almost wholly within the geologically ancient uplands known as the Brazilian highlands. Only small parts of the southern and eastern parts of the state are within the zone of the Great Escarpment. In the southwest, along the border of São Paulo, is the commanding range of mountains known as the Serra da Mantiqueira, whose highest summit, Itatiaia peak (Agulhas Negras), reaches 9,144 ft. This range ends near the easternmost border of São Paulo. The other principal mountain range in Minas Gerais is the Serra do Espinhaço, which begins a little south of Belo Horizonte and extends northward into Bahia. It forms the divide between the rivers draining to the São Francisco (q.v.) and those draining eastward directly to the Atlantic (Doce, Macuri, Jequitinhonha). The greater part of the state consists of a much dissected hilly upland, with hilltops reaching an elevation of about 3,600 ft. above sea level. In the west, on the border of Goiás, Minas Gerais includes a part of the ancient erosion surface still untouched by stream erosion over wide areas and standing about 4,000 ft. above sea level. The stream divides, often erroneously described as mountain ranges, are in fact the undissected remnants of an ancient erosion surface. Minas Gerais is drained to the east and south of the Serra do Espinhaço by the smaller streams named above and by tributaries of the Paraíba river. In the southwest it is drained by the Rio Grande, one of the major headwaters of the Paraná river which reaches the sea at Buenos Aires, Arg. The whole northwest part of the state is drained by the great São Francisco, which flows northward through a rift valley to the west of the Serra do Espinhaço. Along the western border of the state there is a triangular projection (Triângulo Mineiro) lying between the Rio Grande on the south (border of São Paulo) and the Paranaíba river (border of Goiás).

The climate is characteristic of an upland region in the low latitudes. Temperatures are not so high as they are along the coast. At Belo Horizonte (2,800 ft. above sea level) the average of the warmest month (February) is 72.1° F.; and the average of the coldest month (July) is 62.2°. The rainfall throughout most parts of the state averages between 40 and 60 in., but is concentrated in a rainy season between November and March. The period between May and September is very dry, and lack of moisture is a major factor in agriculture along the stream divides. Reflecting these climatic conditions, the southern and eastern part of the state was originally covered with a dense tropical forest.

consisting of many species of trees that retained their leaves throughout the year, but with a few that shed their leaves in the dry season. This semideciduous type of forest was called *mata da primeira classe* ("first-class forest") by Brazilians. On the upper slopes of the Serra da Mantiqueira and of the Serra do Espinhaço the forest gives way to upland meadows or to a scrubby growth of deciduous woodland. All of southwestern and western Minas Gerais is covered by a woodland savanna, consisting of stretches of grassland mingled in complex fashion with stands of woodland. The latter (*campo cerrado*, literally "closed grassland") is made up of low broadleaf trees with gnarled trunks. The woodland species lose their leaves in the dry season. Even in the midst of the woodland savanna, however, semideciduous forests extend along the deeply cut river valleys.

**Agriculture.**—The agricultural area of Minas Gerais is almost exclusively a region once occupied by the semideciduous forest. This forest has been largely cleared by centuries of land rotation. In this system of agriculture, a tenant farmer clears the forest by cutting and burning it at the end of the dry season. He then plants maize, rice, beans and cassava in the newly cleared land, and fair harvests are gained for a period of two or three years before the essential infertility of the soil becomes apparent. He then plants pasture grass, chiefly for cattle grazing, and moves to a new part of the forest. This area is the chief source of beef for Rio de Janeiro, São Paulo and other cities. Dairy farming is important in southern Minas Gerais. In only a few spots is the land used for sugar cane or coffee, which were formerly of greater importance. On the hillsides, which today are used only for poor pasture, the marks of former coffee trees can be seen.

**Minerals.**—Minas Gerais has long been known for its wealth of minerals and for its mining activities (as its name suggests). It supplies half the mineral production of Brazil. Gold was discovered by explorers from São Paulo in 1698. At first the many prospectors who rushed into Minas Gerais only looked for gold in the stream gravels, and today there are many marks of abandoned placer mines at the valley bottoms and on hillsides. The gold was found in the various streams draining away from the Serra do Espinhaço.

In 1729 diamonds were discovered, also in stream gravels, near Tijuco (now called Diamantina). These precious commodities created great wealth in the 18th century, and Ouro Preto (*q.v.*), the administrative centre of Minas Gerais, became a city of great splendour, with numerous beautifully decorated churches. But after 1800 the richest gold sources had been used up, and the miners turned their attention elsewhere. It is interesting, however, that at Nova Lima, a few miles south of Belo Horizonte, a British mining company has been mining gold continuously since 1834. This mine is now one of the world's deepest. In modern times Minas Gerais is also widely known for its semiprecious gems, such as aquamarine, amethyst, tourmaline and topaz. From the high country in the western part of the state come the large quartz crystals that are used in radios.

Of greater importance in the 1960s, however, are the vast deposits of high-grade iron ore and manganese. In the southern part of the Serra do Espinhaço is one of the world's largest stores of iron ore, in which impurities are few and which is so disposed that it can be mined by steam shovels without expensive shafts or tunnels. A huge ore deposit exists at Itabira, on the headwaters of the Doce river, and ore from this source is now exported in small quantities through the port of Vitória (*q.v.*). Another huge deposit near Lafaiete, at the southern end of the Espinhaço, is used to supply the new steel plant at Volta Redonda in the Paraíba valley. Also mined near Lafaiete are the manganese supplies needed for Volta Redonda; and limestone for the new steel plant is supplied from quarries in western Minas Gerais. There are also a number of small, charcoal-burning steel plants, notably at Sabará, Caeté, Barão de Cocais, Monlevade and Itabira. In addition to the iron and manganese, the industrial diamonds and the gem stones, Minas Gerais supplies bauxite, zirconium, iron pyrite, rutile, graphite, chromite, molybdenum, nickel, tungsten, titanium, beryl and mica.

**Tourism.**—Another aspect of the economy of Minas Gerais is tourism. In the Serra da Mantiqueira and in the southwestern uplands of the state to the north of these mountains are a number of resort towns, most of them possessing various hot and curative baths. The mineral waters are bottled and widely dispensed in Brazil. The more important centres are Araxá, Caxambú, Lambari, Poços de Caldas and São Lourenço. Health resorts have also been established at the higher elevations.

**Transportation.**—Minas Gerais is served by railroads, all-weather highways, airports, and by river steamers that descend the São Francisco from Pirapora to Juazeiro in Bahia. The main railroad, Central do Brasil, runs from Rio de Janeiro to Belo Horizonte, with a narrow-gauge extension to Pirapora. To the west of this line is the narrow-gauge Oeste de Minas; east of it is the Leopoldina, also narrow gauge. A railroad also ascends the valley of the Doce river from Vitória to Itabira. It connects with a branch of the Central do Brasil which crosses the Serra do Espinhaço to Belo Horizonte. In the period since World War II, all-weather motor highways have been built to connect Rio de Janeiro with Belo Horizonte, and also São Paulo city with Belo Horizonte. Another road runs through east Minas Gerais to Bahia. Most of these roads parallel the earlier railroads rather than providing feeder service. Away from the main highways and the railroads the roads are passable for motor traffic only in dry weather.

**History.**—Minas Gerais was established as a separate captaincy general in 1720, shortly after the discovery of gold. It has traditionally played an important role in Brazilian politics, in part because of its central position, but also because of the dense population in its southwest. In 1824 Minas Gerais became a province in the Brazilian empire, and in 1889 a state in the federal republic. In 1897 the old colonial capital of Ouro Preto was deprived of its administrative function. The new capital was placed at Belo Horizonte, where a new city, laid out on previously almost unoccupied land, was planned and built. Ouro Preto is a national monument, while Belo Horizonte has become a city with a population (1960) of 642,912.

The second city of the state is Juiz de Fora in the south, noted for its textiles. There is a dense rural population in the south and east, but the whole northern and western part of the state is still very thinly occupied. (P. E. J.)

**MINBU,** a district in Magwe division of the Union of Burma lying in the Dry Belt west of the Irrawaddy river, where there are considerable areas irrigated from the Mon, Maw, Salin and other streams flowing from the forested hills in the west where the district stretches to the crest of the Arakan Yoma. Area 3,602 sq.mi.; pop. (1962 est.) 361,071. Valleys in the foothills are cultivated but tend to be malarial and unhealthy. Dry zone crops (sesame, millet, gram, peanuts) are cultivated in the nonirrigated lowlands of the Irrawaddian tract, but much land is covered with semidesert scrub. Fishing in the Irrawaddy is important. Oil occurs near the mud volcanoes of Minbu, and three small oil fields have been developed in the line of hills (an anticline of Peguan rocks) which runs through Minbu town, and there are other small fields.

Minbu town (pop. [1962 est.] 85,273), the district headquarters, stands on the Irrawaddy. The river there is about 3 mi. wide but with many islands and sandbanks so that in the dry season steamers can come no nearer than four miles south of the town. Salin town is the centre of the northern part of the district. (L. D. S.)

**MIN-CHIA** (Pai), a non-Chinese people centred on Ta-li, Yünnan province, in southwest China. Min-chia is the Chinese name for these rice cultivators, who call themselves Po or Pai in their own language. Occupying a triangular area from Shihkü located on the high Yangtze river down to Hsia-kuan (Siakwan) at the foot of Lake Erh Hai, the Min-chia in the 1960s number nearly 1,000,000, of whom 480,000 live on the fertile plain between the Ts'ang Shan mountains (14,000 ft.) and the lake, which is about 20 mi. long. Until recently the Min-chia language was not written, although commonly spoken throughout the district. It contains many Chinese loan words based on a non-Chinese, tonal, polysyllabic language with a grammatical structure markedly different from Chinese. Since the establishment of the People's Republic of China, the Min-chia, in accordance with the general policy toward non-Chinese peoples, have been given status as a National

Minority and are now organized in an autonomous *chou* (district). Ta-li, the capital of the region, was in the 6th–9th centuries A.D. the capital of the kingdom of Nanchao, the rulers of which were Shans (*see* SHAN). It would seem probable that the Min-chia already then formed the bulk of the population of the district. *See* also TA-LI; CHINA: *The People*.

*See* C. P. Fitzgerald, *The Tower of Five Glories* (1941). (C. P. F.)

**MIND:** *see* PSYCHOLOGY; *see* also CONSCIOUSNESS. For epistemological aspects, *see* KNOWLEDGE, THEORY OF, and articles on the major philosophers there discussed; IDEALISM; INNATE IDEAS. *See* further BODY AND MIND.

**MINDANAO,** second largest island of the Philippines, located in the southern part of the archipelago and comprising Agusan, Bukidnon, Cotabato, Davao, Zamboanga del Norte, Zamboanga del Sur, Misamis Occidental, Misamis Oriental, Surigao, Lanao del Norte and Lanao del Sur provinces. Area, including several small neighbouring islands, 36,537 sq.mi. The rapidly growing population was 5,358,977 in 1960. The island measures 294 mi. north to south and 320 mi. from east to west; it is marked by the long, irregular Zamboanga peninsula on the west. Rugged faulted mountains and volcanoes occur in many areas, particularly paralleling the east coast, along the southwest coast, in the north central part of the island and at the backbone of Zamboanga peninsula. Mt. Apo, 9,691 ft., on the Davao-Cotabato border, is the highest peak in the Philippines. Rolling plateaus characterize central Bukidnon. Broad plains and extensive swamps are found in the valleys of the Mindanao river in Cotabato and of the Agusan river. Narrow coastal plains almost surround the island and broaden considerably near Davao and Pagadian. In the lowlands temperatures average 73° to 83° F. Rainfall varies from 38 to 208 in., averaging about 80 in. a year. Shortly after the advent of U.S. rule Mindanao became the Philippine pioneer frontier. Migration to the island was slow at first, expanded somewhat in the late 1920s and grew rapidly from 1939; following World War II migration from Cebu, the Ilocos provinces, Panay, Negros, Bohol and Manila was resumed. Major crops are corn, rice, abacá and coconuts, with cotton, ramie, coffee and cacao as secondary products. Timber production is high, especially in Agusan and the Zamboanga provinces. Lateritic iron ore reserves in Surigao are large. *See* also PHILIPPINES, REPUBLIC OF THE; and articles on various Mindanaoan provinces. (R. E. HE.)

**MINDANAO DEEP** is a submarine depression in the Philippine sea section of the North Pacific ocean and one of the deepest areas on the earth's surface. The sounding made by the Danish ship "Galathea" in 1951 recorded a depth of 34,583 ft. A subsequent sounding recorded 35,430 ft. It is also known as the Mindanao trench, Philippine trench or Philippine deep. *See* PHILIPPINE SEA. *See* also OCEAN AND OCEANOGRAPHY.

**MINDAUGAS** (d. 1263), the first known ruler of unified Lithuania, is regarded as the founder of the Lithuanian state, though a 13th-century document mentions his father, Rimgaudas, as a "powerful duke who had no equal." After a long struggle with his brother and nephews, Mindaugas *c.* 1236 succeeded in consolidating the whole Lithuanian state, including Lithuania proper, Samogitia and the adjoining Russian territories, under his single rule. He was constantly threatened, however, by his nephews and by other dukes whom he had displaced and sent to the newly won Russian territories; for instance, his nephew Tautvilas and Vykintas, duke of Samogitia, were in alliance with the archbishop of Riga and with Daniel of Halich and Volhynia. Seeking peace with his enemies, Mindaugas decided to accept the proposal of the knights of the Livonian branch of the Teutonic Order that he should be converted to Christianity. He was baptized, along with his family and "a great many of pagans," in 1250 or 1251, and was crowned king at Naugardukas (Nowogródek) in 1253. For a while he remained on good terms with Tautvilas, Daniel and the southern Baltic tribe of the Jotvingai. Between 1253 and 1259 he donated several provinces in what is now northwestern Lithuania to the Livonian knights. Having thus taken care of the west, Mindaugas could win new lands in the east. Between 1237 and 1263 he conducted 20 campaigns into the Russian territories, regained Polotsk and subdued the principalities of Bryansk and Chernigov. Fighting the Tatars many times between 1238 and 1243, he played an important part in stopping their expansion toward the Baltic sea. In the west, however, peace did not last long. Encroachments by the Livonian knights provoked the Samogitians to revolt against them in 1256, and it is presumable that Mindaugas unofficially supported the Samogitians, who won successive victories near Skuodas (1259), at Durbe (1260) and at Lielvarde (1261). In 1261, in any case, Mindaugas broke the peace with the Livonian knights; and it may have been then also that he reverted to paganism. Mindaugas and his sons, Ruklys and Rupeikis, were killed in 1263 in a plot organized by Treniota, a Samogitian leader.

*See* J. Totoraitis, *Die Litauer unter dem Könige Mindowe bis zum Jahre 1263* (1932). (MA. G.)

**MINDEN,** a town of Germany and a *Kreisstadt* (county headquarters) in the *Land* (state) of North Rhine-Westphalia which after partition of the nation following World War II became part of the Federal Republic of Germany. It is situated on the Weser river near the Porta Westfalica (Minden watergap) at the entrance to the North German plain, 71 km. (44 mi.) W.S.W. of Hanover. Pop. (1961) 48,705. The town was founded as a strategic strong point by Charlemagne, who in 800 organized a military bishopric. Subsequently Minden became a trading place of some importance and joined the Hanseatic league. In 1648 the bishopric was converted into a secular principality under the elector of Brandenburg. Frederick II the Great fortified the town, which was held for a time during the Seven Years' War by the French, but after the victory of the British and Hanoverians at the Battle of Minden (1759; *see* SEVEN YEARS' WAR) it reverted to Prussia (British regiments that fought in the battle still wear roses on Aug. 1 as they did on the day of the battle). In 1807 Minden was included in the kingdom of Westphalia, but became Prussian again in 1814.

Historic buildings, grouped together in the centre of the town, include the Early Gothic *Rathaus* (town hall) and cathedral (dating from 952, with an outstanding Gothic nave) which were rebuilt 1948–57 after war damage; also the churches of St. Martin (1029) and St. Mary (12th century) and a number of old houses in "Weser-Renaissance" style.

Minden is an important road and traffic centre on the Cologne-Hanover-Berlin and the Bentheim-Hanover-Bremen railways. It is the junction of waterways where the Mittelland canal-aqueduct (an exceptional engineering accomplishment) bridges the Weser. Industries include the manufacture of textiles, furniture, metal and wood products, glass, ceramics and machinery. Other economic activities are based on farming and cattle breeding in the surrounding area. (W. KR.)

**MINDORO,** seventh largest island in the Philippine archipelago. Area 3,759 sq.mi. Pop. (1960) 311,440. It lies across Verde Island passage from Batangas province, Luzon, and contains a mountainous core surrounded by a discontinuous plain widest along the eastern shore. Lake Naujan, on this eastern plain, is the third largest lake in the Philippines. The rugged interior is peopled in part by Negritos, in part by other primitive groups, *i.e.*, Hanuóo, that practise a shifting slash-and-burn agriculture (*kaingin*). The coastal areas are settled principally by Christian Tagalogs, but Visayans have migrated to the southern part of the island. The timaroo, a small native buffalo, is found only in interior Mindoro.

The island is divided into two provinces, Mindoro Oriental and Mindoro Occidental. The former is the more populous and, since it faces Luzon, is the more progressive and has more commercial activity. The capital and principal town is Calapan (pop. [1960] 33,060). A provincial highway extends from Calapan southward along the east coast to Bongabong and east along the north coast to Puerto Galera, where the University of the Philippines maintains a small marine biological station. The principal products are lumber, rice of both upland and paddy varieties, corn, coconuts, bananas and sweet potatoes.

Mindoro Occidental, fronting on the China sea, is mainly upland. Its principal towns are Mamburao (pop. [1960] 5,832), the provincial capital, in the northwest and San Jose (Panduracan), on

a small plain at the southern end of the island. Principal crops are rice, corn, coconuts and sugar cane. *See* also PHILIPPINES, REPUBLIC OF THE. (AN. C.)

**MIND READING:** *see* PARAPSYCHOLOGY.

**MINE, LAND.** The land mine, an important weapon of World War II, was an encased explosive charge, sometimes laid on the surface of the ground but usually buried just below the surface. According to the type of fuze, it was fired by the weight of vehicles or men, by the passage of time or by remote control. The case was generally circular or square, made of metal or, to combat the magnetic detector, of wood, cardboard, glass or plastics. There were two types of mines, the antitank, to immobilize tanks and other vehicles, and the antipersonnel, to maim or kill soldiers.

**History.**—The ancestor of the antitank mine was the artillery shell buried by the Germans late in World War I to stop British tanks. The true antitank mine and the first antipersonnel mine appeared early in World War II. An economical way of stopping an enemy or restricting his movements, the mine field, composed of both types, was soon widely used by all major belligerents. Land mines were sown by the millions in the tank battles which took place in the north African desert and on the Russian front, and by 1943 had come to be considered almost a new arm of warfare. A postwar study of 10,000 tank casualties showed that 20% had been caused by mines. In the Korean War both the North Korean and the United Nations armies employed land mines extensively. Nuclear mines were not used but it was assumed that they were under development.

**Antitank Mines.**—The antitank mines developed in Great Britain, the Soviet Union and the United States between 1919 and 1939 contained only five or six pounds of TNT. They could stop a light tank, but had to be used in twos or threes against anything heavier. The Germans in 1939 had a mine that was twice as powerful. Their Teller mine (so named because it was plate shaped) had a profound influence on antitank mine history, for it led the Allies to manufacture similar heavy mines. As the Teller type was more likely to immobilize a tank by damaging its track than to destroy it, the emphasis in postwar research was on explosives that would penetrate the hull of a heavy tank and on fuzes that did not depend on pressure.

A standard postwar U.S. army antitank mine contained 12 lb. of TNT and weighed about 20 lb. in all. It required a weight of about 300 lb. to set it off.

In World War II the British and Americans also developed a very light antitank mine consisting of a flat quart can filled with tetrytol. Infantrymen could carry them in their pockets and use them in stacks against tanks or singly against other vehicles. Later this so-called "hasty" mine was given a secondary fuze that would function under the weight of a man; it thus became a combination antitank and antipersonnel mine.

**Antipersonnel Mines.**—The antipersonnel mine, generally containing less than one pound of explosive, could blow off a man's hand or foot or kill him with flying fragments. There were two types, the bounding mine that threw a shell a few feet into the air before it exploded, and the fixed mine that exploded in place. The bounding mine was developed by the Germans before 1939. Called the "S" (spring mine or jumping mine), it was copied by most belligerents and employed with a fragmentation or high explosive shell. The fixed mine was a specialty of the Russians, who organized special battalion-size mine units. The Soviet army used more than 50 models of mines during World War II, but they consisted of three main types: (1) a seven-ounce block of explosive in an oblong wooden box with a hinged lid, which was adopted by Germany and Italy and became known to Allied troops as the dreaded "Schu" (Schutzenmine or "rifleman's mine"); (2) a grooved, cast-iron shell on a wooden stake, which was copied by the Germans in concrete and used in large numbers in Europe; and (3) a cardboard "scatter" mine about the size of a shoe polish can, resembling in size the very small U.S. plastic mine used by the United Nations in Korea. *See* also FORTIFICATION; *Field Fortification in World War II and the Korean War*; AMMUNITION, ARTILLERY.

**MINE, NAVAL.** A naval mine is an underwater weapon used in naval warfare. It may be used defensively, to protect a harbour or naval anchorage against enemy attack; offensively, as in the case of the British mining of the Danube river in World War II; or strategically, as in the U.S. blockade of Japanese shipping lanes which effectively cut off that nation's imports of raw materials. Mines may be laid by surface ships, submarines or aircraft, but all fit a basic description: an explosive charge fitted with a device that will cause it to explode when a target presents itself.

Mines are the only weapons that are not directed against a specific target, in contrast with guided missiles or projectiles such as rockets, torpedoes, bombs, shells and depth charges. These highly mobile weapons have their effective life only during the short time it takes them to travel from point of discharge to point of impact, while the mine, handicapped by its immobility, can sink only those objects that come to it, but its design enables it to wait days or even years for that event. There is also another difference between mines and other weapons: the result of gunfire or bombing, whether hit or miss, is usually plainly and immediately evident, but because of the indirect nature of mine warfare there is no such immediate evidence on which to estimate the effectiveness of minelaying. In fact, mines used with proper strategy can cause great loss even though they are never exploded.

Mines are comparatively cheap weapons to construct, but on a weight basis are the most destructive of all naval weapons because they explode under a ship where the surrounding water, being an excellent conductor of shock, transmits the explosion pulses against the relatively unprotected bottom. This factor, combined with the long effective life, makes the mine a favourite weapon of attrition for use against a strong naval power by a weaker naval power; an effective weapon against the merchant marine of a nation dependent on extensive imports; and a logical weapon to be employed by a self-contained continental power which has little to lose and everything to gain by unrestricted mine warfare.

**Early History and Development.**—Sir William Monson, an admiral in Britain's Royal Navy during the reign of Queen Elizabeth I, first realized that the most vulnerable part of a ship was that beneath the waterline. Monson planned to fire cannons into the underwater bodies of enemy ships from the hold of an attacking ship alongside, but there is no record that he ever tried this plan, which undoubtedly would have resulted in more damage to attacker than to attacked. The first use of a self-contained explosive agent against a ship occurred during the siege of Antwerp in 1585, when the Dutch used small boats filled with gunpowder and exploded by a clockwork device to dispose of several hundred Spaniards. Charles I of England later ordered his master of the ordnance to construct "divers watermines, water-petards and boats to go under water," and such devices were used by the duke of Buckingham, then lord high admiral, during the expedition for the relief of La Rochelle, France, in 1628, although without much success. In neither of these cases was the presence of an enemy ship necessary to set off the explosion, which did not take place under water. A "ship destroying engine" was invented by the marquess of Worcester in 1658. He adopted the Dutch idea of clockwork to explode the mine, but depended on a diver to fasten it to the target, which may have accounted for the fact that it was not used.

Technically, these early devices were delayed-action floating bombs, which could damage the sides of a ship only at or above the waterline, in contrast to the true mine which is designed to hit a ship under water. It should be noted that a torpedo is designed for the same purpose, and for many years the two names were used interchangeably. Robert Fulton applied the term torpedo to one of his mines, possibly because it had the power to stun or make one torpid. Until about 1870 any device which could be exploded under water was called a torpedo. Later, a torpedo was defined as a missile with self-contained propulsion and steering devices. (*See* TORPEDOES.)

American inventiveness was turned to the problems of underwater attack during the Revolutionary War, and David Bushnell,

the "father of the submarine," also became the originator of mine warfare. Bushnell used his submarine, the "Turtle," to carry a mine containing 150 lb. of explosive which was attached to a ship by a screw; the act of releasing the mine from the submarine started a timing mechanism which caused the mine to explode after a predetermined interval. Such a system required both skill and bravery on the part of the crew, who in the person of a sergeant, Ezra Lee, made a one-man attack on the British fleet in the Hudson river. Lee selected the 64-gun ship "Eagle" as the target for the world's first combined submarine and mine attack, but that ship's copper sheathing foiled his efforts with the screw and he was forced to drop his mine and withdraw. Bushnell then devised a form of contact mine, which greatly improved the efficiency of the weapon by eliminating the human factor; this was a keg, filled with gunpowder and supported by floats, which was fired by a gunlock actuated when it struck the target ship. Here was the direct ancestor of all modern mines; it would not explode until the target set it off. One of these "trigger mines" was used with great effect in 1777, when Bushnell launched it against the British frigate "Cerberus" in the Connecticut river; the mine missed that ship but completely demolished a schooner anchored nearby. The next year, on Jan. 7, 1778, Bushnell made another attack on the British fleet in the Delaware river near Philadelphia, Pa., but his kegs were hampered by ice and blew up only one small boat, although they created no little panic among the British. This incident is sometimes referred to as the "battle of the kegs."

The next step in developing underwater warfare was made about 20 years later by another American, Robert Fulton, better known for his success with the steamship "Clermont." Fulton had invented a form of mine, which he termed an explosive carcass, and a submarine, the "Nautilus," to carry it. (It was this vessel on which Jules Verne later based *Twenty Thousand Leagues Under the Sea.*) The French Revolution gave Fulton a chance to test his ideas in 1797, when French ports were blockaded by the British. While Napoleon became interested in Fulton's devices, to the extent of providing a schooner which the inventor managed to blow to bits in a test, his interest waned when negotiations broke down on the issue of granting belligerent status to Fulton and his crew; besides, there was a general feeling among French naval officers that this new form of underwater attack was not in keeping with the traditions of chivalry. (There was some agreement, even after World Wars I and II, that the use of mines is like an unexpected stab in the back, but probably the principal objection to mine warfare, as to atomic, biological and radiological warfare, lies in the fear of retaliation in kind by the enemy. On the other hand, an able tactician will endeavour to surprise an enemy by striking the first blow, and the element of surprise contained in a well-placed mine is not to be overlooked.) Rejected by the French, Fulton went to the British, who, possibly considering the advantages of opportunity over chivalry, decided to use his inventions against the French. The British fleet made an attack on the French off Boulogne in 1804, using Fulton's catamarans, each carrying 40 bbl. of gunpowder, with exploding devices operated by clockwork. Although no damage was inflicted, the French thought even less of the British use of mine warfare than they had of their own.

All early developments in mines were of the noncontrolled or independent type. The first example of a controlled mine, representing the other major classification of mine types, was introduced in 1843 by Samuel Colt, who is better remembered for the revolver bearing his name. Colt experimented with mines fired by electric current supplied from the shore through underwater cables and was finally able to blow up a ship five miles at sea from the control station. Shortly after this, in 1848, a form of controlled mine resulting from German experiments at Kiel university was used during the Schleswig-Holstein war of emancipation to protect Kiel from the Danish fleet. This was the first use of mines as weapons of defense.

Mines were again used defensively during the Crimean War, when the Russians employed contact mines to protect Sevastopol, Sveaborg and Kronshtadt. The fuzes for these mines, designed probably by Alfred Bernhard Nobel, consisted of glass tubes of sulfuric acid which, when broken by a ship's hull, allowed the acid to mix with chlorate of potassium and sugar, generating sufficient heat and flame to set off the main charge of gunpowder.

Both sides employed mines (called torpedoes) in the American Civil War. The most dramatic incident of this mine warfare occurred when Adm. David Glasgow Farragut's squadron was steaming into Mobile bay, in column, under gunfire from Ft. Morgan and the Confederate vessels inside. A new monitor leading the Union line struck a mine and sank instantly. Other ships stopped and massed together blanketing each other's gunfire. Admiral Farragut ordered all to go ahead. Lookouts called out "Torpedoes!" Farragut replied, "Damn the torpedoes! Four bells! Captain Drayton, go ahead! Mr. Jouett, full speed!"

Between the end of the Civil War and the start of World War I the most important development was the perfection by the German mine defense committee of a highly improved method of firing independent mines, the Herz horn. This contained a glass phial of acid solution which on impact was released to become the electrolyte for a primary cell, thus producing sufficient current to fire an electrical detonator. Its technical beauty lies in the fact that it is inert until struck and therefore has an unlimited life.

The buoyant type of mine is held at the desired depth because moored by a heavy sinker laid with it. Until about 1890 all such mines were laid with a preselected fixed length of mooring rope; thus the depth of the mine beneath the surface depended upon placing the unit in a position where the depth of water was accurately known. The two systems of automatic depth-taking that still hold the field are the plummet method and the hydrostatic method. In the former a plummet is released from the sinker directly after laying. The length of plummet line is preselected to equal the depth setting desired. The sinker then sinks, the wire mooring rope connecting it with the floating mine being paid out from a rotating drum in the sinker. The drum can be locked by a spring-loaded pawl but the pawl is held out of engagement by the pull of the plummet. When the plummet strikes the bottom the pawl engages; thus the sinker draws the mine down to a submergence equal to the length of plummet line. In the hydrostatic system the mine is fitted with a hydrostat preset to operate at the depth at which the mine is intended to float; mine and sinker are launched together and sink to the bottom, where either a soluble plug or timing device releases the mine after a safety period that allows the mine layer to get clear. The mine then rises toward the surface on a cable unreeled from the sinker or anchor, carrying with it a hydrostat on a pilot wire attached to the cable reel. When the mine reaches the proper level, reduced water pressure causes the hydrostat to operate, thus setting up a pull on the pilot wire which applies to a brake on the cable drum and stops the mine's ascent.

Mines were used on both sides in the Spanish-American War with no casualties, but the war between Russia and Japan, commencing in 1904, resulted in liberal use of mines by both powers, with effective results. In particular, minefields laid in the open sea were used to influence the movements of an enemy fleet as the first step in a new concept of mine warfare to be greatly exploited in World War I. The Russian fleet, concentrated in Port Arthur, was protected by a series of controlled mines. Early in April 1904 the Japanese laid a minefield of their own off the harbour entrance, attempting to screen this operation by a diversionary torpedo attack which failed to prevent the Russians from observing and plotting the action. The following day a squadron of Japanese cruisers moved into the mouth of the harbour to tempt the Russians out across the minefield, while the main Japanese fleet remained at sea just over the horizon. Adm. Stepan Osipovich Makaroff accepted the challenge and gave chase, but when the full strength of the Japanese forces became apparent he declined action, in the meantime having been maneuvered by Japanese tactics into such a position that a return to harbour would probably involve crossing the minefield. Either the Russians forgot, or else discounted, the minelaying operations of the day before, because they did attempt to go through the minefield, with the result that the battleship "Petropavlovsk" was sunk with 600 casualties, while the "Pobieda" was badly damaged.

A month later the Russians turned the tables on the Japanese,

when the minelayer "Amur," after careful observations of the movements of the blockading Japanese warships, laid a minefield in the patrol area. The battleships "Hatsuse" and "Yashima" both hit mines in this field; the former sank and the latter was abandoned en route to Japan. The Japanese then tried to sweep the area clear of mines, but before the task was completed three of their cruisers were also mined—possibly because Japanese buoys marking safe areas had been moved by the Russians.

The value of accurate knowledge of the location of minefields, whether one's own or the enemy's, was again demonstrated when the Japanese minelayer "Yenisei" was blown up in one of her own fields. This was not the last incident to emphasize that independent mines, once laid, lose all sense of nationality: in World War II, Japan alone lost 21 merchant ships in its own minefields. Before the Russo-Japanese War terminated, Russia had lost a battleship, a cruiser, two destroyers and two smaller craft, while Japan lost two battleships, four cruisers, two destroyers, a torpedo boat and a minelayer, all to mines.

**World War I.**—Mines were used on a vast scale during World War I, with belligerents and neutrals together laying about 240,000, of various types, in all parts of the world. Germany was the first to lay mines outside its own territorial limits, planting a minefield at sea off Lowestoft, Eng., the night of Aug. 4, 1914; in fact, the minelayer "Königin Luise" responsible for this operation was en route when war was declared. By the end of 1914 Britain had established extensive minefields in the English channel to ensure free communications with the continent, and had declared the entire North sea a military area in which designated safety lanes were presumably protected by minefields. Russia mined the gulfs of Finland and Riga in the Baltic sea as protection against German U-boats in that area, while Turkey mined the southern approaches to the Suez canal and the Dardanelles, making effective use of drifting mines in the latter area where the current always moved out into the Aegean sea. As soon as Turkey entered the war Russia also mined the entrance to the Bosporus.

As early as Nov. 1914 the Germans began construction of 15 small submarine minelayers; 96, of varying sizes, were in service during the war. Their first results were achieved the following June, though the element of surprise was partly lost in July when the British salvaged the German UC-2 and proceeded to convert six of their own submarines into minelayers. During the war the Germans laid 43,000 mines, chiefly aimed at Allied shipping, of which they sank 1,000,000 tons. Between May and September 1918 four U-boats laid mines off the east coast of the United States but with little success except for the sinking of the U.S. cruiser "San Diego" off Fire Island. Against British warships German mines were more effective; 40 were sunk, including the battleships "Audacious," "King Edward VII" and "Russell," the cruiser "Hampshire" with Lord Kitchener aboard, and 225 British naval auxiliaries. The Turks scored significant successes in March 1915 when drifting mines in the Dardanelles halted an Allied offensive.

British mines were employed chiefly against the U-boats, though few successes were scored before 1917, when the Mark H-2 mine, based on German models, went into production. Five U-boats were sunk in the Bight before Feb. 1918; thereafter, though the U-boat routes were blocked for days at a time, the mines constantly laid there and in the Kattegat, east of Denmark, took no toll because submarines were escorted through swept channels. The most effective minefield of the war was laid (beginning Nov. 21, 1917) in the Straits of Dover between Folkestone and Gris Nez; by Aug. 1918 the straits, patrolled night and day and illuminated by night, had been sealed with nearly 10,000 mines, and U-boats abandoned the route, passing north of Scotland instead. Between June and October an attempt was made to close this northern exit by laying the Northern barrage from Norwegian waters to the Orkneys (230 mi.). The large central portion contained American Mark VI mines that were detonated electrically upon contact with a 35-foot antenna. The smaller fields at each end contained both British and American mines. In all, 70,000 mines were laid. The results were rather disappointing: three U-boats were certainly sunk, three more may have been sunk, and four were damaged. Submarines found several gaps in the fields—partly because the American mines sometimes exploded spontaneously or at some distance from U-boats—and continued to go through them until the end of the war. Even assuming 100% mine efficiency (which was certainly not afforded by the antenna device) a submerged U-boat had two chances in three of penetrating that barrage unscathed. By the end of Oct. 1918, however, commanders were often reluctant to enter the barrage.

No fewer than 27 U-boats, out of a total of 178 sunk during the war, were certainly sunk by Allied mines, and to this figure can be added almost the same number whose losses can be ascribed, with varying degrees of probability, to the same cause. In addition to these losses, chiefly due to British mines, German mines accounted for about nine U-boats. Most sinkings took place near the German bases or in the Straits of Dover, though a few U-boats were destroyed by mines in British and Russian waters. Great Britain laid about 128,000 mines in all, of which 40% were in enemy waters. British and U.S. minelaying accounted for about 150 enemy warships and naval auxiliaries.

Especially in 1917–18, the mine was the most effective anti-submarine weapon of World War I, largely because U-boat bases were so situated that mines could be laid in their vicinity and along transit routes, and because other weapons had not been fully developed. The mine itself, at first detonated only by contact, was developed in two directions: (1) the British employed magnetic mines of "ground" type (*i.e.*, laid on the seabed) and an acoustic attachment for buoyant moored mines; and (2) they laid shore-controlled fields at the ends of the Dover barrage and elsewhere, accounting for two U-boats sunk and two more severely damaged. (R. McQ. G.)

**World War II.**—Aerial minelaying, considered at the close of World War I, was not actively practised until 1939. By 1943 the British were using Lancaster bombers to drop mines with great accuracy from altitudes of 15,000 ft. In the seven weeks preceding the Allied landings in Normandy in 1944, the British bomber command laid 4,000 mines in enemy waters, accounting for the loss of approximately 100 ships. British bombers also laid mines in the Kiel and Königsberg canals, a feat which involved extremely low-level flying. Although this operation caused the Germans no shipping losses, it resulted in untold losses in delayed cargo movement before the mines could be cleared.

Wellington and Liberator bombers of the Mediterranean Allied air forces also systematically mined the Danube river for a six-month period commencing in May 1944; more than 1,200 mines were laid, resulting in 200 ships sunk. In all British minelaying operations involving aircraft, nearly 55,000 mines were dropped in 21,000 sorties, with the loss of 500 planes.

In the Pacific, aerial minelaying was carried out by U.S. army air forces, the Royal Air Force and the Royal Australian Air Force. The first minelaying mission by U.S. B-29 bombers, and also the longest combat mission of any kind during the war, took place on Aug. 10, 1944, when Superforts based in Ceylon flew 3,800 mi. round-trip to Palembang in Sumatra, where 16 mines dropped sank three Japanese ships and damaged four more.

The first mining of a harbour by planes flying from aircraft carriers was conducted in April 1944 when U.S. carrier forces raided Palau in the Caroline Islands. In order to prevent ships in the harbour from escaping it was necessary to mine the channels after the raid commenced. In broad daylight and under anti-aircraft fire, planes from the "Lexington," "Bunker Hill" and "Hornet" laid 78 mines, as a result of which, according to Japanese reports, "for 20 days all channels were closed to navigation."

Only a few mines had been laid in Japanese waters until the last few months of the war. In late 1944 and early 1945 the capture of air bases within practical bomber range of Japan gave every prospect of success for an aerial minelaying campaign designed to cut Japanese lifelines to the Asian mainland and the Indies. Submarine attacks on Japanese shipping had already forced most ocean-going traffic into a few crowded, mineable channels opening into the Inland sea.

On March 27, 1945, army B-29s dropped 900 mines in the approaches to Shimonoseki strait, which at that time handled 40% of all Japanese marine traffic. Before the war ended ten weeks

later more than 12,000 mines had been laid from the air, effecting a blockade that took a staggering toll of shipping and almost completely cut off raw materials desperately needed by Japan. Magnetic, acoustic and pressure-type mines were laid, some with ship-counting devices which allowed a specified number of ships to pass before they exploded, thus foiling too-eager minesweepers. In laying this blockade, army air forces flew a total of 1,529 sorties to drop 12,135 mines, with a loss of only 15 aircraft. The effectiveness of this operation is shown in figures for Japanese shipping losses credited to mines after March 27, 1945: April, 16 ships; May, 65 ships; June, 58 ships; July, 65 ships; August (9 days), 16 ships. Japanese losses from mines laid by U.S. planes for the entire war totaled 257 ships, with a combined tonnage of 580,360.

*Submarine Minelaying.*—To a large degree, aircraft replaced submarines as minelayers during World War II, but submarines were used by both Allied and Axis powers. Six British submarine minelayers (of which four were lost in operations) laid about 3,000 mines, accounting for 67 enemy vessels (59 sunk). During the early months of the war, U.S. submarines concentrated their efforts on the hunting down and torpedoing of Japanese naval and merchant vessels, and it was not until a shortage of torpedoes developed that the submarines had space to carry mines. It should be noted that as a U.S. submarine lays mines from its torpedo tubes, its load of torpedoes is reduced or eliminated completely by minelaying activities and its combat potential is restricted accordingly. The first U.S. submarines to mine enemy waters, in Oct. and Nov. 1942, laid mines from the Gulf of Siam to Kii Suido at the eastern entrance to Japan's Inland sea. These early mining expeditions, aside from actual destruction of Japanese shipping, provided valuable pointers for later mine planting, among them the conclusion that minefields laid in shallow coastal areas were valuable even though they sank no ships, because they forced shipping out into deeper water where the submarines could do the sinking.

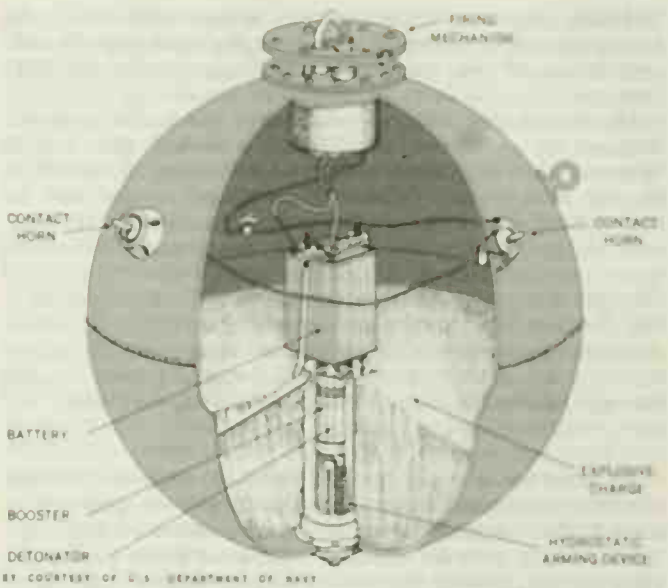
Many more minefields were laid in the Pacific by U.S. submarines operating out of Hawaii and Australia. The British submarines "Porpoise" and "Rorqual" and the Royal Netherlands submarine O-19 also laid mines in the Pacific.

*Japanese Mine Warfare.*—Japan made extensive use of mines. One vast minefield was laid from Formosa to Kyushu to keep U.S. submarines out of the East China sea, and another concentration of mines plugged the Strait of Formosa. The principal gates to the Sea of Japan, the straits of Tsushima, La Pérouse and Tsugaru, were mined, as were many other navigable channels in the Philippines, the Dutch East Indies and the Sulu archipelago.

The Japanese placed great faith in their type 93 mine, a moored contact mine fired by chemical horns, which could be used in water as deep as 550 fathoms. These mines conformed to requirements of international law in that they disarmed themselves if their mooring cables broke and they went adrift. The Japanese also used type 92, a moored controlled mine, in defensive fields for harbours. The type 92 carried 1,100 lb. of explosive and was fitted with hydrophones and magnetic detectors intended to warn the shore control station when a submarine approached. A third type of mine used was a moored contact mine laid in fields in the open sea. U.S. submarines managed to keep clear of the controlled minefields during the entire war, although three were lost to contact-type mines.

Japan lost 21 merchant ships in its own minefields. The small bag of submarines taken by Japanese mines is accounted for partly by the fact that sonar enabled U.S. submarines to keep clear of mines, and partly because Japanese notices of minefields, issued to warn their own ships of such dangers, sometimes were recovered by Allied personnel, with the result that these submarines often knew as much about Japanese minefields as the Japanese did.

*Mine Warfare in the U.S.*—German U-boats laid a total of 11 minefields off east coast ports in 1942 and 1943. These ventures cost Germany at least two submarines, sunk by aircraft almost as soon as they laid their mines, and resulted in several sunken or damaged ships. Not all the minefields laid were effective; four of them, including one off Boston, Mass., and one off Charleston, S.C., were either badly laid or consisted of defective mines and were not discovered until the war was over; their location was



BY COURTESY OF U.S. DEPARTMENT OF NAVY

FIG. 1.—CUTAWAY DIAGRAM OF CONTACT MINE

"Unarmed" mine is put into ready-to-fire condition when hydrostatic arming device reacts at a predetermined water depth. If a ship strikes a contact horn, an electrical current activates the firing mechanism. This switches on the battery, which sends a strong current through the detonator, firing the booster and exploding the charge

disclosed by German records. A field of 15 mines laid by the U-701 in the Chesapeake capes ship channel was the most effective, sinking the S.S. "Robert C. Tuttle," the British trawler "Kingston Ceylonite" and a coal barge. The steamer was later salvaged. The tug "J. R. Williams" was sunk by another field off Delaware. Mines forced the closing of the port of New York for two days, but no ships were lost in that area. Five German minefields were discovered and cleared before they caused any damage.

*Summary.*—It is estimated that British, dominion and Allied ships, including minelayers, destroyers, submarines, motor torpedo boats and motor launches, laid 206,969 mines in enemy waters during World War II, while aircraft laid another 53,552 mines. In addition, British surface minelayers laid about 185,000 mines in fields designed to discourage or to divert enemy shipping or U-boat movements. These included a barrage across the English channel, an extensive system off the east coast of Great Britain, a series of anti-U-boat minefields between Scotland and Iceland and between Iceland and Greenland, and fields in the approaches to the Irish sea and between Portsmouth and Cherbourg. Germany laid about 120,000 mines around northwest Europe and no small number in the Mediterranean, where Italy assisted in the operation. The U.S. laid about 25,000 mines in the Pacific, while Japan may possibly have laid three times that many.

Admiralty figures on Axis naval and merchant losses as the result of British minelaying indicated that a total of 1,050 such ships were sunk and another 540 damaged. Britain lost 281 naval vessels of all types to Axis mines, in addition to 296 merchant vessels. The total of merchant ships lost by the other Allies reached 521. The U.S. navy lost six destroyers and destroyer escorts, three submarines, nine large minesweepers and minelayers, two auxiliary craft and some small unnamed craft to mines. Japan lost 19 naval vessels and 247 merchant ships for a total of 266, out of which British mines claimed 10, Netherlands mines 2 and Australian mines 9.

At the close of 1947 it was estimated that a total of 251 ships of all nations had been mined in various parts of the world since the war ended, either by drifting or unswept contact mines.

**Korean War.**—The Korean War demonstrated the classic use of mines by a land power to hamper operations of a strong sea power. By extensive use of mines the North Korean forces achieved an initial surprise, sank or damaged several U.S. and South Korean ships, successfully interfered with U.S. fleet movements and tied up much Allied effort in minesweeping. Mines

laid from sampans took their toll first in Sept. 1950, sinking the U.S. minesweeper "Magpie" and damaging destroyers "Brush" and "Mansfield" and the Republic of Korea minesweeper YMS 504.

Mines used were Russian-made moored and ground magnetic-influence types. Extensive minefields off the east coast port of Wonsan, where U.S. minesweepers began clearing a channel on Oct. 10, 1950, actually delayed an amphibious landing there for one week; the 250-ship armada could not land its 50,000 troops, even though the city was in friendly hands, until about 2,500 mines were cleared out. The U.S. minesweepers "Pirate" and "Pledge" and the R.O.K. minesweeper YMS 516 were sunk in this operation; the "Partridge" was later mined in Korean waters. Attempts were made to "countermine" these mines by carrier aircraft dropping bombs in the water, but with no success. During this war helicopters proved valuable in locating minefields.

## TYPES OF MINES

All naval mines are of two general types, controlled or independent. Controlled mines can be made safe or dangerous as needed; their dependence on shore control and observation stations, plus the need for extensive underwater power and control cable systems, restrict their use to harbour defense areas where their laying or removal, while complicated, does not present the problems encountered in open seas or in enemy waters.

The greater percentage of mines used in modern warfare have been independent mines of two general classes: moored and ground mines, the latter resting on the sea bottom. Moored mines may be either contact (fired when hit by a ship) or influence mines; ground mines are, for obvious reasons, always influence mines.

**Magnetic Mines.**—These were used by the British as early as 1917, although it was not until the Germans commenced using aircraft to lay them in British harbour entrances during Sept. 1939 that they became a major threat. The operation of the magnetic mine depends on the fact that a steel ship acquires both permanent and induced magnetism; the firing mechanism of this mine is designed to be actuated by a ship's magnetic field. The unit for measuring magnetic induction is the gauss. Protection against magnetic mines is obtained by degaussing ships, or reducing their magnetic fields. This was achieved by passing an electrical current through a permanent coil, or degaussing girdle, which was built around the hull in a horizontal plane. Eventually, two simpler methods of degaussing were developed. "Flashing" involved placing a huge temporary coil around the ship and reversing the polarity of the permanent magnetic field. However, the process was expensive and each treatment lasted only a few months. "Wiping" consisted of simply moving a single cable, with about a 3,000-amp. load, up the ship's side, section by section, with the same results as from flashing. Another process, called deperming, referred to all steps taken to reduce the ship's permanent magnetic field, after which degaussing reduced the induced magnetic field almost to a zero condition.

Sweeping magnetic mines required that the minesweeper produce a magnetic field strong enough to detonate the mines, at a safe distance from itself. Eventually a type of buoyant cable was developed through which an electric current could be pulsed; each minesweeper towed two of these cables, one several times longer than the other, with an electrode at the end of each, and a current pulsed through the cables set up a field strong enough to detonate any mine in an area between the ends of the two cables and for some distance on either side. Two minesweepers steaming abreast of each other could thus clear a much wider path, and by timing the pulse intervals in accordance with their speed it was possible to make the fields overlap each other and produce a continuous sweep.

**Pressure Mines.**—This type of mine, simple in operation, involves a principle long known to canal engineers: beneath every ship in motion in shallow water there is an area of reduced pressure, and this reduction in pressure depends on the ship's draft and speed. The pressure mine contains a chamber divided into two parts by a diaphragm, with one side of the chamber open to the sea. The diaphragm is so constructed that any decrease in pressure on the sea side causes it to bend toward that side sufficiently to close a firing circuit and explode the mine. A small leak hole between the open and closed sides of the diaphragm serves to equalize pressure on both sides and to take care of slow changes such as those caused by tides, but a ship passing over the mine will reduce the pressure too fast for the leak hole to equalize and will thus fire the mine. The pressure mine's outstanding advantage is that it reacts only to a low-pressure change equal to that produced by a ship or an object the size of a ship, thus making it practically impossible to sweep. Pressure mines, first used by the Germans in 1944, were developed by both Britain and Germany, but as neither nation had found an effective countermeasure, they were reluctant to use them and invite retaliation in kind. Allied ships were informed of safe speed limits to use in sailing over pressure mines in order to avoid setting up the critical low-pressure effect, but this procedure could be used only by smaller ships.

*Sweeping Pressure Mines.*—Since pressure mines are fired by the reduced water pressure produced by a ship passing over them, the best method of sweeping them is to simulate the passage of a ship by towing a large, expendable target over them—a slow and sometimes costly procedure, as the exploding mine is likely to damage the target to the point where it must be laid up for repairs. Too, there is always the chance that heavy swells might temporarily inactivate the mine at the exact moment of sweeping. The Japanese had some success in sweeping these mines with bottom trawl nets and also used divers in some cases, but this was usually in the ratio of one diver to one mine. The U.S. used "guinea pig" ships in Japanese waters after World War II: they were damaged cargo ships, operated by volunteer crews at remote-control stations on the upper decks, which made high-speed runs through swept areas to see if all mines had been swept.

Because heavy seas sometimes actuate these mines—strong gales off the Normandy beaches in particular saved Allied minesweepers the work of sweeping some German pressure mines—it was U.S. practice to combine pressure mines with magnetic or acoustic mechanisms. In heavy swells, minesweepers had only to set up magnetic or acoustic influences to sweep the mines. In general, pressure mines retain a high nuisance value in comparison with other types.

**Acoustic Mines.**—These mines depend on a simple microphone which picks up and amplifies the sound of a ship's propellers or engine. As drifting mud or silt and accumulating marine growth foul the mine, it requires an increasingly higher sound level to fire it. In addition, the continuous drain on the battery will eventually sterilize the mine. Acoustic mines are swept by minesweepers using mechanical noisemakers, such as an air hammer heating on a steel plate. British sweepers used both built-in and towed-type "hammer boxes" in sweeping German acoustic mines. U.S. sweepers used the towed type of noisemaker exclusively. So far as is known, the Japanese laid no acoustic mines in the Pacific, but the U.S. used two different types, each responsive to different frequency bands of noise. Acoustic systems may be combined with magnetic systems by arranging for the firing mechanism to be cocked by an acoustic unit and triggered by a magnetic unit.

## MINESWEEPERS

Minesweeping is the term applied to the process of clearing an area of mines; the vessel which performs this task is a minesweeper by employment if not by design. The minesweeper's place in naval warfare is well described in "The End of an Empire," vol. iv of *Battle Report:* "It is always the minesweeps that spearhead an invasion; it is always the minesweeps that open up the vital gap through which the amphibious forces pour their massed weight. And it is almost always a minesweep that gets sunk first" (Capt. Walter Karig, Lieut. Comdr. Russell L. Harris and Lieut. Comdr. Frank A. Manson, Rinehart & Co., Inc., 1948).

Sweeping mines laid by an enemy is only part of the minesweeper's task; equally important and every bit as hazardous is the business of sweeping up one's own mines in order to render sealanes safe for maritime commerce. The earliest sweeping system, devised to clear anchored contact mines, consisted of two ships

BY COURTESY OF U.S. DEPARTMENT OF NAVY

FIG. 2.—U.S.S. "CONQUEST," AN OCEAN-GOING, NONMAGNETIC COASTAL MINESWEEPER, 172 FT. IN LENGTH, 630-TON DISPLACEMENT, SPEED OF 15 KNOTS

steaming across a minefield towing a wire rope between them. The wire was kept at the necessary depth by otters, a sort of underwater kite, and mooring lines of mines were cut by sawlike projections on the sweep wire or by cutting jaws. When the released mine floated to the surface it was destroyed by gunfire.

Fishing boats were first used by the British for minesweeping during World War I, but they were too slow for operations with the fleet. Special minesweeping vessels were designed, followed by high-speed minesweepers which could sweep at speeds up to 25 knots. At the same time the British developed the Oropesa sweep, named for the first ship to experiment with it, which provided a means of protection for all the minesweepers in a sweeping operation except the leader. The Oropesa sweep was a long cable, supported at the outboard end by a float, held at the proper spread by an otter and maintained at the proper depth by a kite at the inboard end, which swept a path to one side of the course followed by the minesweeper. Each following sweeper thus sailed in a swept channel. With the introduction of high-speed destroyer-type minesweepers using an Oropesa sweep on each side at once, a spread of about 450 yd. could be cleared at low speeds; the sweeps were modified so that increased speed reduced the spread to about 150 yd. at 25 knots.

For the protection of ships at sea in unswept areas, paravanes were devised and were used by both warships and merchant ships by 1917. The paravane is a torpedo-shaped float towed by a cable attached to a ship's forefoot and equipped with a rudder and planes which cause it to tow well submerged and to one side of the ship. With a paravane streamed to each side, the tow wires form a wedge which deflects anchored mines—unless hit bow on—away from the ship and along the towline to the paravanes, where heavy wire cutters shear the mooring cable and let the mines float to the surface.

At the close of World War I, both Great Britain and the U.S. engaged in a vast minesweeping campaign. By Nov. 1919 the British had swept more than 23,000 mines, with the loss of only six minesweepers, as compared with the loss of 214 sweepers during the war. The U.S. took on the task of clearing the North sea barrage; about 90 ships swept 56,033 U.S. and 15,093 British mines in an area of 5,000 sq.mi. between the Orkney Islands and the Norwegian coast. The impossibility of obtaining 100% success in clearing all such mines was demonstrated in July 1947 when a World War I-type mine was found off Cape May, N.J.

With the build-up of naval strength commencing in 1938, the U.S. added large numbers of minesweepers to the fleet, which at that time depended for such service on the "Bird" class minesweepers left over from World War I. Some high-speed minesweepers were converted from World War I-type destroyers; others were converted, during the war, from "Bristol" class destroyers. About 70 of the "Raven" class minesweepers, with speeds of 18 knots, were commissioned; another 130 "Admiral" class sweepers and about 70 "Accentor" class coastal minesweepers also joined the fleet. Other minesweepers were converted from trawlers, purse seiners and tuna clippers (all types of commercial fishing boats). Smallest sweepers were the 200-ton motor minesweepers, of which more than 450 were in service.

The extensive use of magnetic mines by Communist forces during the Korean War led to U.S. development of new types of wooden-hulled, nonmagnetic sweepers to replace most steel-hulled World War II types. Identified as MSO's, they displaced from 600 to 800 tons and were less than 200 ft. in length.

MSO's had plywood hulls, stainless steel alloy engines and metal fittings of aluminum, brass or magnesium. Approximately 100 steel-hulled sweepers of the World War II type remained in service. Another addition to the U.S. minesweeping force was the minesweeping boat (MSB) that was only 57 ft. long and displaced about 44 tons. These vessels were completely nonmagnetic, were equipped to sweep contact, magnetic or acoustic mines and were operated by a crew of six enlisted men. The U.S. navy also developed helicopter minesweepers; the powerful, slow-moving "whirly birds" can hover safely above the sea while towing minesweeping gear which explodes magnetic or acoustic mines.

During World War II U.S. minesweepers took part in every combined landing assault and many fleet operations. Before the Normandy landings, 255 minesweepers were assembled in England. On the opposite side of the world, when the U.S. fleet moved into Leyte gulf in Dec. 1944, 65 minesweepers were in the van. From the time sweeping started until the war ended U.S. minesweepers cleared about 10,000 mines; it was estimated that there remained in the Pacific alone 100,000 mines which had to be swept before safe navigation could be ensured. British, Australian and Dutch minesweepers took over the task of clearing the Asian coast off Formosa and the islands south of the Philippine Islands, while U.S. minesweepers cleared fields off the Philippine Islands, East Hainan strait, the Palaus, Marshall and Gilbert islands, Truk, the Bonins and Japan. At the peak of these operations, which were completed in March 1946, about 300 Japanese-manned minesweepers were assisting 374 U.S. minesweepers.

*Mine Watching*.—During World War II, Allied and Axis nations in Europe, and the Japanese, during the last months of the war, used mine watchers to detect night-flying minelaying aircraft and to mark exact locations of dropped mines, thus expediting their removal. Great Britain maintained mine watchers after the war and organized the Royal Navy mine-watching service in 1951. A uniformed civilian organization affiliated with and administered by the admiralty, it included shore-based watching posts with necessary plotting instruments and communications equipment and floating watching posts for all major ports and waterways consisting of a mother ship and several smaller watching craft. A port mine-watching service officer was stationed at each major port. Members of the service, frequently with prior military service, were recruited, furnished distinctive uniforms and trained in essential duties.

In the European theatre, from Sept. 3, 1939, to June 13, 1945, British and other Allied minesweepers cleared 20,429 mines, exclusive of U.S. operations. A total of 1,533 ships were used, of which 263 were lost. During the next three years, an international organization initiated by the British admiralty cleared 125,000 mi. of sea-lanes. About 1,900 minesweepers of many nations engaged in this project, destroying 12,000 mines.

**MINEHEAD,** a market and seaside town and urban district in the Bridgwater parliamentary division of Somerset, Eng., on

the Bristol channel, 24 mi. N.W. of Taunton. Pop. (1961) 7,674. It owes its origin and growth to its good harbour, and there is still in existence a record of the port dues charged in 1350, although it was not until 1558 that the town was granted a charter of incorporation by Elizabeth I. This was revoked by James I, but until the Reform act of 1832 Minehead continued to send two members to parliament. A weekly market and annual fair were held from the 15th century, and since the reign of Edward IV the fair has been held on the Wednesday in Whitsun week. Buildings of interest include St. Michael's church (1450); Quirke's almshouses (1630), the Old Manor office; and the 17th-century cottages at the Quay and Church steps. The present harbour was built in 1616. During the 17th century Minehead was a thriving port conducting a considerable trade with the West Indies and other colonies, but now only coasting vessels use the harbour. Minehead's main industry is tourism, although light industry, notably shoemaking and the manufacture of electrical components, has been established in the town.

**MINEOLA,** a village on Long Island, New York, U.S., the seat of Nassau county, lies midway across the county at the junction of the main line and the Oyster Bay branch of the Long Island railroad. In the 17th century both the Dutch and English, who crossed Long Island sound from Connecticut, made settlements on Long Island (*q.v.*). Both started farming what was called Hempstead plains. Mineola, then called Hempstead Branch, was a part of the Hempstead plains. In 1858 the name was changed to Mineola. When Nassau county was created in 1898 by dividing Queens county, Mineola was made the county seat; in 1906 it became an incorporated village. Near Mineola are Roosevelt field (closed 1951; the site of a shopping centre), where many of the great names in flying made early aviation history, and Mitchel air force base (closed 1961). For comparative population figures *see* table in NEW YORK: *Population*. (D. L. D.)

**MINE PROSPECTING AND DEVELOPMENT.** The search for economically useful mineral deposits is called prospecting. Prior to the 20th century, mineral deposits were found by prospectors roving the surface of the earth looking for visible evidence of mineralization. Valuable minerals were recognized by their various distinctive physical properties. Gold occurs in nature as a heavy, malleable, yellow metal. The most important mineral of lead, galena, is dark gray, heavy and lustrous. The first ores of iron to be mined were deposits of magnetite, a black, heavy mineral capable of magnetically attracting a piece of iron. All three of these minerals are eye-catching. (*See* also METALLURGY: *History.*)

**Geologic Methods.**—As the deposits of minerals that cropped out at the surface of the earth were mined, the search for additional supplies of minerals took a more sophisticated turn. The science of geology was used to explain the occurrence of ore deposits. It was discovered that certain types of mineral deposits are associated with certain types of rock and geologic land forms and structures. (*See* GEOLOGY: *Physical Geology: Economic Geology.*)

Minerals of the common metals, copper, lead and zinc, generally form in igneous rock, which is formed by the cooling of masses of molten minerals at or near the surface of the earth. Wherever igneous rock came into contact with a bed of sedimentary rock a favourable location for the concentration of metallic minerals resulted (*see* ORE DEPOSITS). By mapping the rocks that crop out at the surface of the earth, geologists can sometimes infer such locations even though the contact between the sedimentary rock and the igneous rock does not appear at the surface. Drilling holes for samples of rock at depth will then confirm or disprove the existence of a mineral deposit at such a location. (*See* also MINERALOGY: *Geologic Occurrence and Origin.*)

**Geophysical Methods.**—As the science of physics progressed in the methods of measuring the properties of matter, these methods of measurement were adopted by prospectors to help find deposits of minerals that possess some detectable property not discernible to the naked eye. Probably the first use of a geophysical instrument to aid in the discovery of minerals was the use of a compass to locate bodies of magnetic iron ore. Prospectors found that a dip needle, a compass held in a vertical plane, could be used to find magnetic bodies that could not be seen at the surface. An instrument known as a magnetometer, which can detect very small forces of magnetism, was developed and is used extensively in the search for completely buried mineral deposits.

Often the mineral possessing the magnetic property, magnetite, is associated with more valuable minerals of copper, lead and zinc, and the magnetometer can be used to prospect for this type of deposit also. This instrument has been developed to the point where it can be used effectively from an airplane.

Another property that minerals possess is density. Some minerals are much heavier or much more dense than others and this difference in density can sometimes be detected with an instrument known as a gravimeter. Gravimetric methods were used to locate deposits of chromite, a heavy mineral of the metal chromium, in Cuba during World War II.

Some deposits of sulfide ores possess characteristic electrical properties. Acting like giant batteries, these deposits can cause the flow of electric currents in the ground surrounding completely buried deposits of these materials. These currents can be detected at the surface by sensitive voltmeters.

Metallic ores are generally much better conductors of electricity than the surrounding barren rock. A more sensitive and selective electrical method of prospecting involves the injection of an electric current into the ground by means of a generator and ground electrodes. The flow of this manufactured electricity will be concentrated in the best conductors. By means of an instrument known as a galvanometer, the path of flow of this electric current can be traced, and if a metallic ore is present beneath an overburden of soil and rock it can be detected.

The principle of electromagnetic induction can also be used to locate mineral deposits. These methods utilize the physical principle that an artificially created electromagnetic field will induce a flow of current in an electrical conductor. The flow of current in the conductor, a conducting ore body in the case of mineral exploration, will in turn induce a secondary electromagnetic field which can be detected at the surface of a buried deposit. As well as being used to find deposits, these electrical methods are often used to help determine the size and depth of known ore deposits.

Seismic methods of prospecting employ knowledge gained in the study of earthquakes. Different types of rocks will transmit earthquake waves with different velocities. An artificial earthquake can be created by exploding a charge of dynamite in a hole drilled into the surface of the earth. The exact time of the explosion is recorded and the time of arrival of seismic waves at a number of stations is also recorded. The seismic waves also travel down into the rocks of the earth and are reflected like sound waves from the boundaries between layers of different kinds of rock. The time it takes for these echoes to arrive at the recording station is determined and the velocity of the seismic wave can be computed. From the velocity of the wave, the type of rock through which the wave passed can be determined. Geologic structures can also be defined by this method, and favourable locations for the formation of oil reservoirs can be recognized. The seismic method is the most important geophysical prospecting method used in the search for new oil fields (*see* PETROLEUM).

Ores of uranium and thorium emit radiation that can be detected with an instrument known as the Geiger counter. A more sensitive instrument used in the detection of nuclear radiation is the scintillation detector. Uranium and thorium ores exposed at the surface can be easily found with this instrument. When uranium ores are covered by an overburden of loosely consolidated material they may still be detected. In the radioactive decay process a gas, radon, is formed which can migrate away from the ore deposit of uranium. This gas can work its way toward the surface, where it decays and forms elements which are also radioactive. This radioactivity can be detected by a scintillation detector or Geiger counter carried over the ore deposit.

For detailed discussion of geophysical methods and their application *see* GEOPHYSICAL PROSPECTING.

**Geochemical Methods.**—Geochemical prospecting methods involve chemical analysis for traces of metals in soils, vegetation and stream water or silt. The weathering of metal-bearing ores at the earth's surface results in a residual soil containing a higher than normal amount of the metal. Traces of this metal also find their way into the vegetation growing over the metal deposit and into water and sediment of streams flowing away from the deposit. Although to the unaided eye such metal-rich soils, vegetation and water are identical to normal materials, they can be distinguished by the chemical tests for the metals they contain. These simple tests, though extremely sensitive, are inexpensive and well-fitted to the pocketbook of the independent prospector.

**Prospecting Fields.**—Prospecting is carried on most intensively in areas where chances are best for the discovery of large-tonnage but relatively low-grade deposits that can be worked profitably by modern mining methods. An area is generally considered promising if some valuable deposits have been found there in the past and if there is reason to believe that other similar deposits remain to be found by the application of modern exploration techniques. To this should be added the requirement that political conditions be favourable for a heavily capitalized industrial operation. These conditions are met, for example, in the following areas:

1. The Pre-Cambrian shield of central Canada, where major deposits of nickel and uranium have been found.
2. Southern Arizona, where two very large copper deposits are being developed.
3. An area including southern Peru and northern Chile, where several major copper deposits are being developed.
4. Central Africa, where extensions of the rich Rhodesian copper belt are being sought.

Mention should also be made of the flurry of uranium prospecting in the Colorado plateau following World War II, that led eventually to the discovery of the major uranium deposits of the Ambrosia lake district in New Mexico. (*See* also NATURAL RESOURCES.)

**Exploration.**—After a mineral deposit is found by the prospector, its size and richness must be determined. Various geophysical methods can be used to some extent in this operation, known as exploration. Most commonly, either a percussive (churn) or rotary drill is used. The churn drill is simply a heavy steel chisel suspended on a steel cable or rod. The steel chisel is raised and dropped on the ground, crushing the rock and forming a hole. Water is placed in the hole to hold the crushed rock in suspension during the drilling process. Periodically, the crushed rock is bailed from the hole and this material is sampled and analyzed for its mineral content.

Rotary drills used to explore mineral deposits are capable of drilling 20,000 ft. into the earth. The diamond rotary drill has a hollow, cylindrical, diamond-studded bit which can cut a cylinder from the rock through which it passes. This rock cylinder is recovered and its mineral content is determined. While the percussive or churn drill can drill only vertical holes, the diamond drill can drill holes in any direction. Holes are drilled at measured distances across the ore deposit and the size and richness of the deposit can be estimated. (*See* also DRILLING MACHINERY.)

A profitable mine demands an economic balance between size and grade of the deposit, ease of transportation, availability of a market, availability of competent labour and political stability of the controlling government. Thus, a very low-grade but large copper deposit in the U.S. can be mined economically using skilled labour and mechanization while a much richer deposit in a remote area of the world may be uneconomic to mine.

**Development.**—If the main body of an ore deposit is near the surface, it can be mined as an open-pit mine and its development would entail the removal of the overburden. If the deposit is to be mined by underground methods, development entails the sinking of shafts, the installation of hoisting equipment and the driving of openings or tunnels through the ore body. Additional information on the shape and size of the ore body and the physical character of the ore and the surrounding rock is obtained during the development stage and many other factors, such as the type of artificial support required by the tunnels, the amount of water that has to be pumped from the underground workings and the ventilation that will be required, are determined.

*Mine Surveying.*—Once exploration is started, surveying assumes great importance in mining. The position and depth of all the exploration drill holes are accurately determined with surveying instruments. From these data, maps, which are blueprints for the mining engineer and geologist, are prepared which delineate the ore deposit in three dimensions. The locations of all tunnels, shafts and veins of ore are carefully recorded on these maps. Because the surveying is done in very close quarters and often in very wet or very dusty atmospheric conditions, special instruments are used for mine surveying.

For mining methods and production see MINING, METAL. *See* also COAL AND COAL MINING; COPPER; DIAMOND; LEAD; SALT DOME, etc. (H. E. H.; J. L. MO.)

**MINERAL DEPOSITS:** see ORE DEPOSITS.

**MINERALOGY,** one of the geological sciences, is concerned with the study of minerals—the naturally formed and generally inorganic solid substances composing the crust of the earth, meteorites and other planetary bodies. The domain of mineralogy includes discovery, identification, description and classification of the different mineral species; study of their geological occurrences; explanation of their nature and properties; explanation of their origins; and consideration of their practical uses. In referring to minerals it should be borne in mind that popular usage of terms frequently differs from scientific usage. In everyday speech, the term mineral is likely to cover a great variety of inorganic matter, even that in foodstuffs. For scientific purposes, the term is reserved for substances having essentially the following characteristics: natural occurrence, homogeneity, definite chemical composition or ranges in composition, regular internal structure, and inorganic nature (with but few exceptions). However, as is the case for most natural substances, there exist many intermediate varieties between materials clearly covered by any simple definition and those that are not. The following examples illustrate some of the boundaries of the term. Coal is not a mineral because it is inhomogeneous, is composed chiefly of organic substances and is wholly to largely noncrystalline. On the other hand, two liquids, at ordinary temperatures and pressures (the usual reference conditions of man), are included as minerals—water and native mercury. A few natural crystalline organic compounds are also included as minerals (*e.g.*, whewellite, hydrous calcium oxalate, $CaC_2O_4 \cdot H_2O$).

This article presents a general survey of and introduction to the science of mineralogy and its more significant problems, directions, implications and applications, with special attention to developments in the second half of the 20th century. In addition to the cross references given in the various sections of this article further discussion of theories, concepts and techniques referred to will be found in the articles GEOCHEMISTRY; CRYSTALLOGRAPHY; GEOLOGY; PETROLOGY; METAMORPHISM; SEDIMENTARY ROCKS. *See* also separate articles on individual species and groups of minerals, as: FELDSPAR; HALITE; QUARTZ; etc.

VI. Experimental Mineralogy

## I. HISTORY

The planet earth is a great ball of minerals. Not only do the minerals largely determine man's physical environment, but they

FIG. 1.—MOST MINERAL CRYSTALS OCCUR WITHOUT FACES (ANHEDRAL CRYSTALS) AND AS CRYSTALLINE AGGREGATES IN THE FORM OF ROCKS. SHOWN ABOVE ARE TWO TYPES OF CRYSTALLINE AGGREGATES AT THREE LEVELS OF MAGNIFICATION

*Above left:* olivine crystals forming the rock dunite, an example of an essentially monomineralic aggregate. (Top left) specimen (from Jackson county, N.C.) in which the individual crystals can scarcely be distinguished. (Top right) cut and polished surface of the specimen magnified 2 ×. Light green grains are magnesic olivine, $(Mg,Fe)_2SiO_4$; dark spots are magnetite, $FeFe_2O_4$, and serpentine, $Mg_3Si_2O_5(OH)_4$. (Bottom) polarized light photomicrograph of a thin section of the specimen, magnified 12 ×, in which the individual crystals stand out clearly. Almost all the grains are olivine. The different colours are due to the optical effect of the different orientations of the olivine crystals on the polarized light. *Above right:* quartz, feldspar, biotite and hornblende crystals forming the rock granite, an example of a polymineralic aggregate. (Top left) specimen of St. Cloud granite (from Minnesota). (Top right) cut and polished surface of the rock magnified 1½ ×. Large pink crystals are microcline feldspar, $(K,Na)Si_3AlO_8$; white ones are sodic plagioclase feldspar, $(Na,Ca)Si_2Al(Si,Al)O_8$; small smoky ones are quartz, $SiO_2$; black spots are biotite, $K(Mg,Fe,Al)_3(Si,Al)_4O_{10}(OH,F)_2$, and hornblende, $(Ca,Na)_3(Mg,Fe,Al)_5(Si,Al)_8O_{22}(OH,F)_2$, not distinguishable from one another. (Bottom) polarized light photomicrograph of a thin section of the rock magnified 12 ×. White and gray crystals are quartz. Light to dark bluish-gray ones are feldspar: those with irregular crosshatching are microcline perthite; those with finely ruled parallel lines are sodic plagioclase. Most of the green and brown crystals are biotite; the brown one in the centre is hornblende

provide also the ultimate source of a vast number of raw materials and much of the energy essential to him. Minerals are, therefore, of great interest from many points of view and have been intimately associated with the material and intellectual development of mankind. Earliest man used stones, clay, colourful or shiny mineral pieces and crystals, and rarely occurring native metal for implements, building materials, pigments, charms and ornaments almost as furnished by nature. Later, metals were extracted from ore minerals, building blocks and bricks were worked from stone and clay; and pottery and glass were manufactured from clay minerals, feldspar and quartz. In modern times, an ever growing host of chemicals, metals, other useful products and energy are obtained directly and indirectly from mineralogic sources (*see* NATURAL RESOURCES: *Minerals*).

Although man has speculated on the "nature of things" since prehistoric times, scientific study of minerals scarcely began much before the 19th century. Moreover, the study was largely descriptive until well into the 20th century by virtue of the extremely complex nature, properties and occurrences of minerals. This complexity has required that mineralogy utilize an extensive application of other sciences such as geology, crystallography, mathematics, many branches of chemistry and physics, metallurgy and ceramics. The development of mineralogy has depended, therefore, upon a co-ordinate development of these other sciences.

The earliest surviving work on minerals is that of Theophrastus, *On Stones* (*c.* 315 B.C.). It appears to have been part of a much larger treatise that has been lost. The most important mineralogical writings of classical times are the last five "books" (chapters) of *Natural History* by Pliny the Elder (*c.* A.D. 77). The books summarize the knowledge (correct and incorrect) about the mineral kingdom held by the classical authorities up to that time. The modern aspect of mineralogy began with Georgius Agricola (*q.v.*), "father of mineralogy," and the publication of his *De natura fossilium* (1546) in which he classified minerals on the basis of physical properties and presented an extended description of the different varieties, many of them new. After Agricola, the attempts to develop the ideal classification polarized into: (1) the natural history method (*e.g.*, C. Linnaeus, 1735; F. Mohs, 1820), based on external characters; and (2) the chemical method (*e.g.*, A. F. Cronstedt, 1758; J. J. Berzelius, 1814). However, some mineralogists, notably A. G. Werner (1774), compromised with mixed systems.

Reliable quantitative chemical analysis of minerals was begun about 1800 by M. H. Klaproth and was widely and successfully applied by C. W. Scheele and Berzelius. During the same period, J. B. L. Romé de Lisle (1772) and especially R. J. Haüy (1801) laid the foundations of crystallography. W. H. Wollaston's invention (1809) of the reflecting goniometer (*q.v.*) made possible precise and rapid measurement of the angles of crystals. It then became apparent that chemical composition and crystallographic

characters are the fundamental properties of minerals. E. Mitscherlich's explanation (1819) of the puzzling phenomenon of isomorphism, that is, the similarity of crystalline form in substances that are chemically related, laid the beginnings of the modern crystallochemical approach to mineralogy. The improvement of the polarizing microscope by H. C. Sorby, his use of it (1849) to study extremely thin slices of rock (thin sections), and the determination and compilation of mineral optical data by A. des Cloizeaux (1867) and others inaugurated the third and final major approach of classical mineralogy.

The more recent direction of mineralogy was stimulated by Max von Laue's brilliant suggestion (1912) that crystals could diffract X-rays. Shortly thereafter, W. H. Bragg, W. L. Bragg and others began the development of X-ray diffraction techniques and employed them in the study of mineral construction. Soon after, V. M. Goldschmidt and his co-workers laid the foundations of crystal chemistry. In an equally important development, N. L. Bowen and his co-workers began a comprehensive program of investigating experimentally the complex conditions under which minerals form.

## II. NATURE OF MINERALS

The obvious properties of minerals, such as size, shape, colour and markings, are not essential or particularly informative ones. In fact, they tend to obscure those that are. Accordingly, minerals must be investigated by means of the less obvious properties, and special techniques must be devised to measure and interpret them. Crystal morphology, diffraction of X-rays, crystallophysical behaviour (e.g., optics) and chemical composition are the most informative. They are also of great value in determining the identity of mineral species and varieties. The nonessential properties are of interest chiefly as supplemental descriptive properties; they may aid in mineral identification in certain cases.

**Morphological Crystallography.**—The first information about the nature of minerals came from the study of the angular relationships and schemes of arrangement of crystal faces and cleavages (crystal morphology). (*See* figs. 1 and 2.) Such study, which began with and was long restricted to minerals, developed eventually into the independent science of crystallography. The most informative regularities in behaviour discovered were what are now known as the law of constancy of interfacial angle, the law of rational intercepts and the principle of symmetry. They indicate that minerals have characteristic internal structures made up of periodic arrays of submicroscopic "building blocks" (unit cells). Crystal morphology provides information about the shapes and relative dimensions (axial angles and ratios) of the building blocks but not their absolute dimensions or contents. An extended account of the subject is given in the article CRYSTALLOGRAPHY.

FIG. 2.—ALTHOUGH MINERAL CRYSTALS BOUNDED BY FACES (EUHEDRAL) ARE IN THE MINORITY, THEY RECEIVE THE MOST ATTENTION BECAUSE OF THEIR BEAUTY AND THE STIMULUS THEY GAVE TO THE DEVELOPMENT OF CRYSTALLOGRAPHY AND MINERALOGY. ABOVE ARE FOUR EXAMPLES OF REPRESENTATIVE MINERALS SOMETIMES OCCURRING IN EUHEDRAL CRYSTALS

(Top left) wulfenite ($PbMoO_4$) from Chihuahua, Mexico; (top right) microcline feldspar ($KAlSi_3O_8$), var. "Amazon stone," with smoky quartz, from Colorado; (bottom left) pyrite ($FeS_2$) from Butte, Montana; (bottom right) calcite ($CaCO_3$) from Chihuahua, Mexico

**Structural Crystallography.**—The development of X-ray diffraction in 1912 opened up a completely new avenue of approach to crystallography and to the nature of minerals (*see* CRYSTALLOGRAPHY: *Crystal-Structure Analysis*; X-RAYS). It now became possible to determine the detailed internal symmetries (space groups), absolute dimensions and atomic contents of the building blocks (unit cells), and thus the crystal structures of minerals. The first substances investigated by the new technique were mostly minerals, and within a few years a large number of crystal structures had been worked out, especially by the Braggs (father and son) and their co-workers.

More recently, electron diffraction, infrared spectroscopy, neutron diffraction, and nuclear and electron spin resonance also have become valuable tools of structural crystallography. These newer methods confirm and add a large volume of significant detail to the results of X-ray diffraction.

Structural crystallography established as fact the deduction of classical morphological crystallography that each mineral species is characterized by its chemical constituents and their ordered arrangement. It further established that the solid state is essentially the crystalline state. Most of those minerals once thought to be amorphous (noncrystalline) are, in actuality, extremely fine crystalline (cryptocrystalline) aggregates. However, no clear cut discontinuity exists between the crystalline and the rarely occurring amorphous state.

**Chemical Composition.**—Accurate determination of mineral composition is more difficult than would appear. Not only are many compositions extremely complex but most minerals exhibit appreciable ranges (solid solution) and many exhibit great ranges in composition. Moreover, most minerals occur intimately intermixed with one or more others, and some minerals, notably the common rock-forming and ore minerals, may be intergrown on such a fine scale that the inhomogeneity can be observed only by methods such as optical and electron microscopy, or X-ray and electron diffraction (*see* fig. 3). Thus much difficulty has been experienced in understanding the true chemical nature of minerals. In a large part, progress in this direction has followed the coordinate development of crystallographic technique and theory.

Although almost all of the 90 or so natural elements play some part in mineral composition, by far the most important ones are oxygen (60.5%), silicon (20.4%), aluminum (6.2%), hydrogen (2.8%), sodium (2.5%), calcium (1.9%), iron (1.9%), magnesium (1.8%), potassium (1.4%) and titanium (0.2%), which compose 99.6 atomic per cent (relative numbers of atoms) of the earth's crust. Important subsidiary elements are carbon (0.08%), phosphorus (0.05%), manganese (0.04%), sulfur (0.03%) and fluorine (0.03%). The remaining elements are extremely rare and are contained in abundance only in minerals other than the rock-forming ones. These minerals compose an almost infinitesimal fraction of the crust. Many of the rare elements also are widely dispersed as traces in solid solution in the rock-forming minerals. In addition to the common metallic and nonmetallic elements, hydrogen is a significant constituent in many minerals and one that was commonly overlooked even as recently as the 1930s. It occurs in water molecules in crystal hydrates, in adsorbed water molecules, in hydroxyl (OH) ions, and less commonly as cations (giving rise to hydrogen bonds).

**Crystal Chemistry.**—Modern mineralogy makes extensive use of crystal or solid-state chemistry which combines crystallography and chemistry into a powerful unified approach. Much of the development of this field was based upon the study of minerals, and its early history is largely a part of the history of mineralogy.

FIG. 3.—AGGREGATION AND INTERGROWTH OF ORE MINERALS AT MEGASCOPIC AND MICROSCOPIC SCALES

Most minerals, including ore minerals, are intimately and complexly intergrown. (Left) aggregate of copper ore minerals (from Arizona) composed mainly of bornite, $Cu_5FeS_4$, (reddish purple where freshest, iridescent blue to green where tarnished) with small amounts of covellite, CuS (dark blue and difficult to distinguish from tarnished bornite), chalcopyrite, $CuFeS_2$ (yellow), chalcocite, $Cu_2S$ (not visible) and quartz and altered rock (white and light gray). (Top right) photomicrograph of a polished surface of a specimen similar to some of the small dark blue patches in the specimen at left, magnified 125 ×. What appears megascopically to be wholly covellite is actually mainly bornite (faintly pinkish background in greenish-gray areas) that has been partly and pervasively replaced by extremely fine-grained covellite (greenish-gray). The covellitized bornite is itself intergrown with chalcocite (light gray), chalcopyrite (yellow), and a few anhedral crystals of enargite, $Cu_3AsS_4$ (gray). (Bottom right) photomicrograph of centre portion of polished surface above, magnified 250 ×, showing covellitized bornite (pink to red) more clearly; much more bornite is present than is apparent at lower magnifications. Also present are chalcocite (gray), chalcopyrite (yellow) and tiny crystals of pyrite, $FeS_2$ (pale yellow) in the chalcocite veins

Crystal chemistry considers the forces bonding atoms together, the gross and detailed features of crystal structures, the chemical-structural behaviour of the elements, and the explanation of the nature and properties of minerals and other crystalline matter. The great bulk of minerals, including the halides, most oxides and oxysalts (*e.g.*, carbonates, silicates) may be considered as ionic crystals (*see* SOLID STATE PHYSICS). They consist of positively charged cations (metallic elements) and negatively charged anions (nonmetallic elements) bonded together by electrostatic attraction. Native nonmetallic elements and many sulfides, on the other hand, are predominantly covalently bonded. Metallic bonding occurs in the native metals and some sulfides. Some minerals—*e.g.*, brucite, $Mg(OH)_2$, molybdenite, $MoS_2$, goethite, $HFeO_2$—are held together by weak van der Waals forces or by hydrogen bonding (*see* VALENCE; *The Hydrogen Bond*) as well as by ionic or by covalent bonding. (*See* fig. 4.)

Many properties such as crystal optics, habit, cleavage, the greasy feel of talc and graphite, conductivity and adsorption depend at least in part upon the bonding present.

The crystal structures of minerals range from the simple (halite) to the complex (feldspars, tourmaline). Consideration of many structural features is simplified by the use of the geometric conception of co-ordination. Co-ordination refers to the array of immediate neighbour atoms (or ions) around a given kind of atom (or ion). Crystal structures can be readily described and analyzed in terms of different combinations of linked co-ordination groups. The related concept of close-packing is also of extremely useful application because in a great many minerals the nonmetallic atoms (notably oxygen and sulfur) not only occupy most of the volume but are in (or close to) a close-packed arrangement. The structures of such minerals, therefore, are based upon a close-packed arrangement of nonmetals with the metal atoms occurring in the interstices.

There exist two crystallographic kinds of close-packing—hexagonal and cubic. Both have two sets of interstitial voids; each void of one set is surrounded by six nonmetal atoms (sixfold or octahedral co-ordination); and each of the other set by four (fourfold or tetrahedral co-ordination). Thus, the crystal structure of halite, NaCl, is described by stating that the chlorine anions are cubic close-packed and the sodium cations occupy the octahedrally (sixfold) co-ordinated sites. In sphalerite $\beta$ZnS, the sulfur atoms also are cubic close-packed, but the zinc atoms occupy the tetrahedral (fourfold) position. In wurtzite $\alpha$ZnS, on the other hand, the zinc atoms again occupy tetrahedral sites, but the sulfur atoms occur in hexagonal close-packing. In the more complex structure of olivine $Mg_2SiO_4$, the oxygens are approximately hexagonal close-packed and the metals occupy both types of sites, the silicons occurring in tetrahedral interstices and magnesiums in octahedral ones. (*See* also INTERMETALLIC COMPOUNDS.)

A notable early triumph of crystal chemistry was the explanation of the structure and properties of the complex silicate minerals. Their fundamental constructional unit is the silicate tetrahedron $[SiO_4]$, a co-ordination group of four oxygens around each silicon atom. These tetrahedral groups occur in different schemes of linkage so as to form different silicate anion radical types whose structures and formulas are illustrated in fig. 6. The structure of each silicate species is built with units of a particular kind of anion group bonded to one another by cations in the interstices between them. Many mineral properties such as crystal habit, cleavage, optics, viscosity in the molten state, adsorptivity, reactivity and geologic occurrence are controlled or influenced by the kind of silicate radical present. Because of this close connection of crystal structure with mineral properties it is common practice to write the chemical formulas as structural formulas. Thus, the formula $KAl_2[Si_3AlO_{10}](OH)_2$ for muscovite indicates that two structural species of aluminum atoms are present; one-third of the aluminum atoms are tetrahedrally co-ordinated ("tetrahedral aluminum") and two-thirds are octahedrally co-ordinated ("octahedral aluminum"). The tetrahedral aluminum is structurally similar to silicon and the two species together form alumino-silicate sheets (having the characteristic ratio of tetrahedral atoms to oxygen of 2:5).

Many different minerals (*e.g.*, halite, NaCl, periclase, MgO, and galena, PbS; barite, $BaSO_4$, celestite, $SrSO_4$, and crocoite, $PbCrO_4$) have the same kind of crystal structure, a property termed isostructuralism. On the other hand, some substances with the same chemical composition have different structures, the property of polymorphism. The structural differences can be of any degree. Some polymorphs (different forms having the same composition) have distinctly different atomic arrangements and are clearly different crystal or mineral species (*e.g.*, calcite and aragonite, $CaCO_3$; pyrite and marcasite, $FeS_2$; andalusite, sillimanite and kyanite, $Al_2SiO_5$). Others, such as the temperature modifications of certain minerals (*e.g.*, high- and low-temperature quartz, high- and low-temperature albite), differ so slightly that they are simply structural variants of a mineral species. Many of the minor polymorphic differences are caused by differences in kind and degree of structural order. Thus, microcline and sanidine, $(K,Na)Si_3AlO_8$, differ from one another in the positional order (sequence) of the aluminum and silicon atoms in the tetrahedral sites in the alumino-silicate framework (*see* FELDSPAR). Moreover, certain minerals (*e.g.*, wurtzite, clays and micas) have subtle variants (polytypes) due to different schemes of order in the stacking of their constituent layers (*see* MICA). The silica

minerals (quartz, tridymite, cristobalite and coesite, $SiO_2$) provide an especially notable illustration of variety in kind and number of different arrangements of the same atomic constituents (*see* SILICA). The particular polymorph present in a mineral system depends upon many factors, such as the temperature, pressure and composition of the environment during formation, the mechanism and rate of crystal growth, and the later thermal and mechanical history of the system.

Many mineral properties arise from the fact that real crystals are imperfect in terms of the ideal model of classical crystallography. The imperfections include various types of atomic thermal motion, vacant sites, interstitial atoms, impurity atoms, site disorder, dislocations and mosaic or domain structures. The colours, for example, of certain varieties of normally colourless minerals (*e.g.*, quartz, fluorite, halite) are attributed to colour centres, a type of imperfection in which electrons are trapped in vacant anion sites. Fluorescence and other varieties of luminescence result from the promotion of extra energy levels by certain impurity atoms.

**Solid Solution.**—The occurrence of ranges in chemical composition is an especially characteristic property of minerals. The phenomenon is termed solid solution and is caused by such mechanisms as simple proxy, cluster proxy, omission, interstitial "stuffing" and mixed crystals. In simple proxy, chemically different species of atoms are structurally equivalent (*e.g.*, magnesium and ferrous iron; aluminum and silicon; fluorine, hydroxyl and oxygen) and occur in different proportions to one another in the same kind of sites. For example, magnesium, ferrous iron and manganese occur in octahedrally coordinated sites between the independent silicate tetrahedrons in olivine $(Mg,Fe,Mn)_2SiO_4$. All ranges between occupancy entirely by magnesium or by iron can occur, whereas only a relatively small proportion of the sites can be occupied by manganese. That is, solid solution is complete with respect to magnesium and iron but limited for manganese. Where solid solution involves atoms of unlike valence (*e.g.*, Al and Si), electric neutrality is maintained by complementary proxy that compensates for the charge difference. Cluster proxy occurs in a few minerals whereby atomic clusters such as $Cl_2$, $CO_3$ or $SO_4$ substitute for one another. Such proxy is restricted mainly to minerals having large voids as in the framework types of silicates (*e.g.*, feldspathoids, scapolites).

Formulas for minerals are both compositional and structural; the symbols and their subscripts indicate the composition, and their location in the formula tells something about their structural function. Solid solution is symbolized by enclosing the structurally equivalent constituents in parentheses as follows: $(Mg,Fe)$. Two cases are: (1) complete solid solution, common in the so-called ferromagnesian minerals, *e.g.*, olivine, $(Mg,Fe)_2SiO_4$; and (2) limited solid solution with one or more dominant constituents (which may be indicated by underlining) and one or more less important but characteristic constituents, *e.g.*, microcline $(K,Na)(Si_3Al)O_8$ and biotite, $K(\underline{Mg},\underline{Fe},Al)_3(\underline{Si},Al)_4O_{10}(OH,F)_2$.

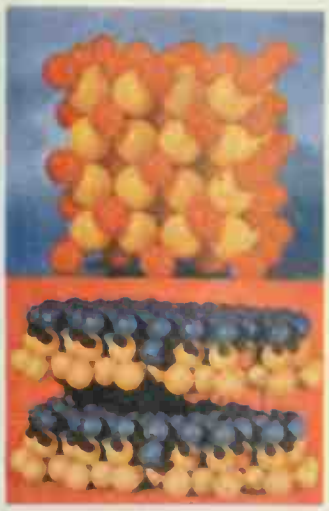

FIG. 4.—MODELS OF TWO TYPES OF CRYSTAL STRUCTURES OF MINERALS (TOP) FLUORITE, $CaF_2$, AND (BOTTOM) KAOLINITE, $Al_2Si_2O_5(OH)_4$, THE SIZES OF THE BALLS ARE SCALED IN PROPORTION TO THE IONIC RADII OF THE ATOMS THEY REPRESENT

(Top) crystal structure of fluorite, an example of strong ionic bonding. Red balls represent calcium and yellow balls fluorine ions. (Bottom) structure of kaolinite, bonded by covalent, ionic and van der Waals forces (*see* text). Yellow balls represent oxygen atoms arranged in sheets of tetrahedra (*see* Figs. 5 and 6); tiny silicon atoms occur within the tetrahedral pores and are not visible. Small brown balls are aluminum and blue are hydroxyl (OH) ions. The closely packed atoms in the composite slabs are held together by strong covalent and ionic forces; the slabs, however, are electrically neutral and only weakly held to one another (note large separation distance) by van der Waals bonding

Compositional variations involving departures from the low stoichiometric ratios (simple combining proportions) of classical chemistry are common among the sulfide and related minerals. Atomic omission (by metals, nonmetals or even both) is the most common cause. In pyrrhotite, for example, as many as one-fifth of the metal sites may be vacant (symbolically $Fe_{1-x}S$ with $x$ between 0 and 0.2), and in skutterudite as many as one-sixth of the nonmetal sites may be vacant—$(Co,Ni)As_{3-x}$ with $x$ between 0 and 0.5.

Much solid solution commonly attributed to simple proxy is due more probably to mixed crystals. They consist of extremely minute (at or near the atomic scale of magnitude) domains having similar or closely related structures but different pure or nearly pure end-member compositions. The domains are arranged to form single crystals, as far as ordinary methods of observation are concerned. All gradations probably can occur between a random sequence of solid solution constituents in simple proxy to the more ordered domains composing mixed crystals.

The extent of solid solution, whatever its mechanism, is controlled by the structural similarity and availability of the atoms involved, the nature of the host structure, and the temperature, pressure and composition of the environment of crystal growth. Structural similarity is related particularly to atomic size and bonding behaviour. High temperature promotes solid solution whereas low temperature inhibits it. Many minerals, notably feldspars and ore minerals, were formed originally at high temperatures with considerable solid solution and have exsolved or unmixed to separate phases of "purer" crystals upon later cooling. Much mineralogical research is devoted to the relationship of the solid solution compositions of co-existing minerals with temperature and to the application of this relationship to geologic thermometry.

## III. CLASSIFICATION AND NOMENCLATURE

In principle, a mineral species is defined by its chemical composition and crystal structure. (*See* fig. 5.) In practice, however, the principle often is difficult to apply and the differentiation of many species must be made somewhat arbitrarily. For example, complete solid solution can exist between gold and silver but the series is, by convention, split into the two species, native gold (Au,Ag) and native silver (Ag,Au). The boundary is set at the solid solution composition of equal numbers of gold and silver atoms. The complete solid solution series between magnesium and iron orthosilicate, on the other hand, is accepted as a single species, olivine $(Mg,Fe)_2SiO_4$.

Many structural differences also are gradational so that species distinctions based on them must in many cases be

FIG. 5.—ELECTRON MICROGRAPH OF KAOLINITE CRYSTALS, $Al_2Si_2O_5(OH)_4$, MAGNIFIED 24,000 ×, SHOWING THE MINUTE SIZE AND THE CRYSTAL NATURE OF THE CRYSTALS. KAOLINITE, A CLAY MINERAL, IS ONE OF THE SILICATES (*see* FIGS. 4 AND 6)

arbitrary. Generally, individual polytypes, that is, different forms of a single species (*e.g.*, those of wurtzite), are not recognized as different mineral species, although species status has been given (partly on historical grounds) to certain clay and micalike minerals whose chief differences are attributable to polytypism. The total number of recognized mineral species, therefore, depends upon the criteria applied and differs with the authority. Something on the order of 1,500 species are accepted by modern criteria, although more than 8,000 different names, most of them based on trivial differences, have been applied.

Modern classifications are based on chemical composition and crystal structure. The chief divisions are chemical classes based on the nonmetal or anion radical present. The most important classes are: elements, sulfides (and the related arsenides, tellurides, sulfosalts), oxides (and hydrous oxides), halides, carbonates, borates, phosphates, sulfates, tungstates and silicates. The classes are further divided into chemical types and these into isostructural groups of the individual species. The silicate class is a particularly important one. It contains one-quarter of all the mineral species, a score of which make up more than 90% of the earth's crust. The silicates are subclassified into structural divisions essentially along the lines shown in fig. 6 (*see* also figs. 4 and 5). (*See* also SILICON: *The Silicates.*)

Most mineral names, in modern practice, are characterized by a terminal "ite," a custom begun by the Greeks and Romans in naming stones. Mineral nomenclature is essentially the same throughout the English-speaking world since American and British mineralogists agreed on a uniform system around 1936. German and French nomenclature is essentially similar to it. Nonetheless, variation exists in the method of naming varieties of solid solution series. Although a scheme utilizing compositional modifiers (*e.g.*, magnesian olivine, manganoan calcite) along the lines proposed by W. T. Schaller, or one indicating symbolically a composition more quantitatively (*e.g.*, olivine $Fo_{75}$, plagioclase $An_{31}Ab_{66}Or_3$) would be desirable, a large number of individual varietal names are still widely used (oligoclase for plagioclase $An_{10-35}$, freibergite for argentian tetrahedrite, ankerite for ferroan dolomite).

## IV. DESCRIPTIVE AND DETERMINATIVE PROPERTIES

Crystal properties fall into two classes—scalar, which have magnitude only (density, chemical composition), and vectorial, which depend also upon direction (crystal faces, cleavage, refractive indices).

**Chemical Properties.**—In ordinary determinative work chemical properties are utilized mainly for confirmatory partial qualitative tests. Among the methods devised to deal with the extraordinary variety of chemical combinations occurring in the natural compounds, blowpipe methods, flame colorations, fused bead colorations and certain wet tests of ordinary qualitative analysis are much used. Such tests are described in the textbooks of mineralogy listed in the *Bibliography*. However, macrochemical tests commonly are inadequate, especially for the ores, because minerals are almost always intimately intergrown. Accurate identification of the opaque minerals commonly requires selection of minute samples under the reflecting microscope (*see* METALLOGRAPHY) and the use of microchemical tests.

Increasing use is made of partial quantitative analytical methods such as colorimetric tests, flame photometry, optical spectrography, and X-ray fluorescent spectrography for the determination of solid-solution composition (because of its significance in connection with the environmental conditions during mineral evolution).

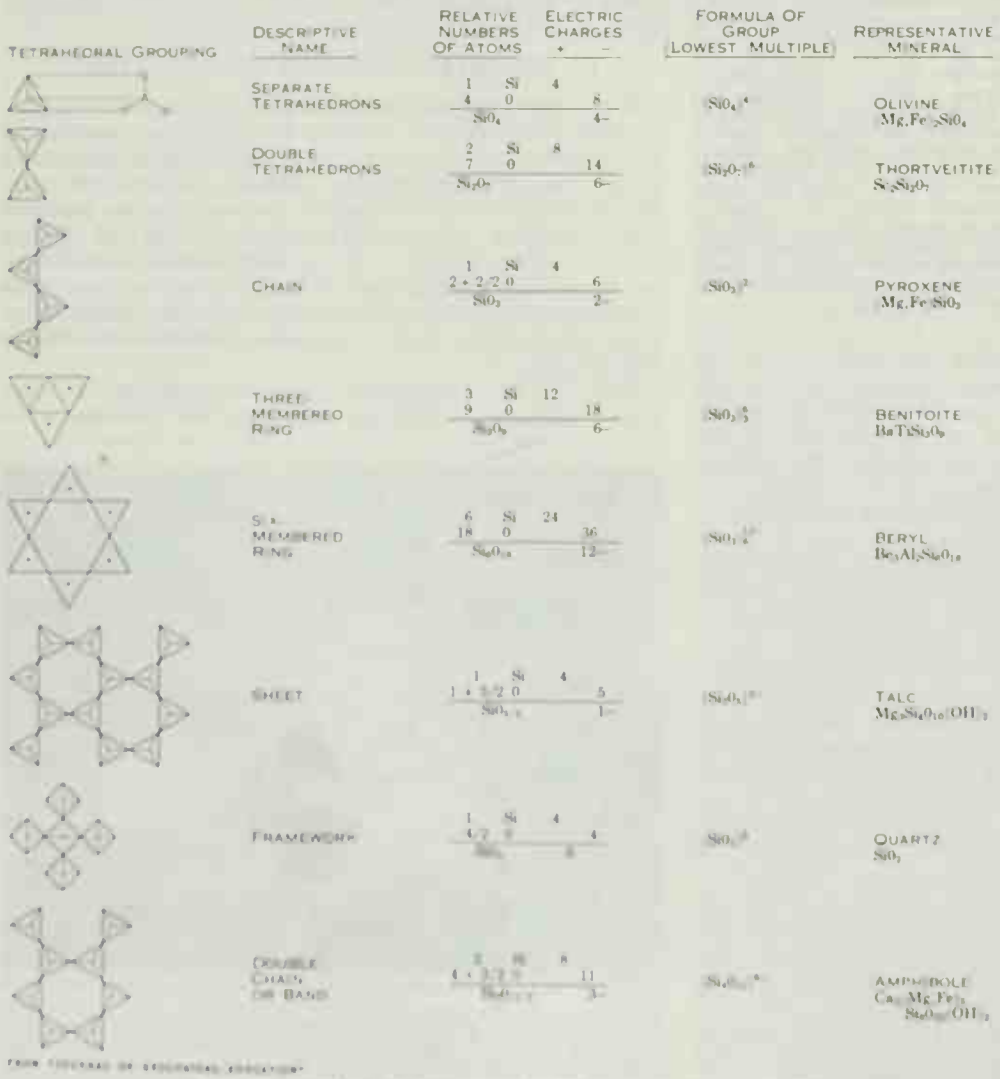

FIG. 6.—STRUCTURES AND COMPOSITIONS OF SILICATE RADICAL TYPES

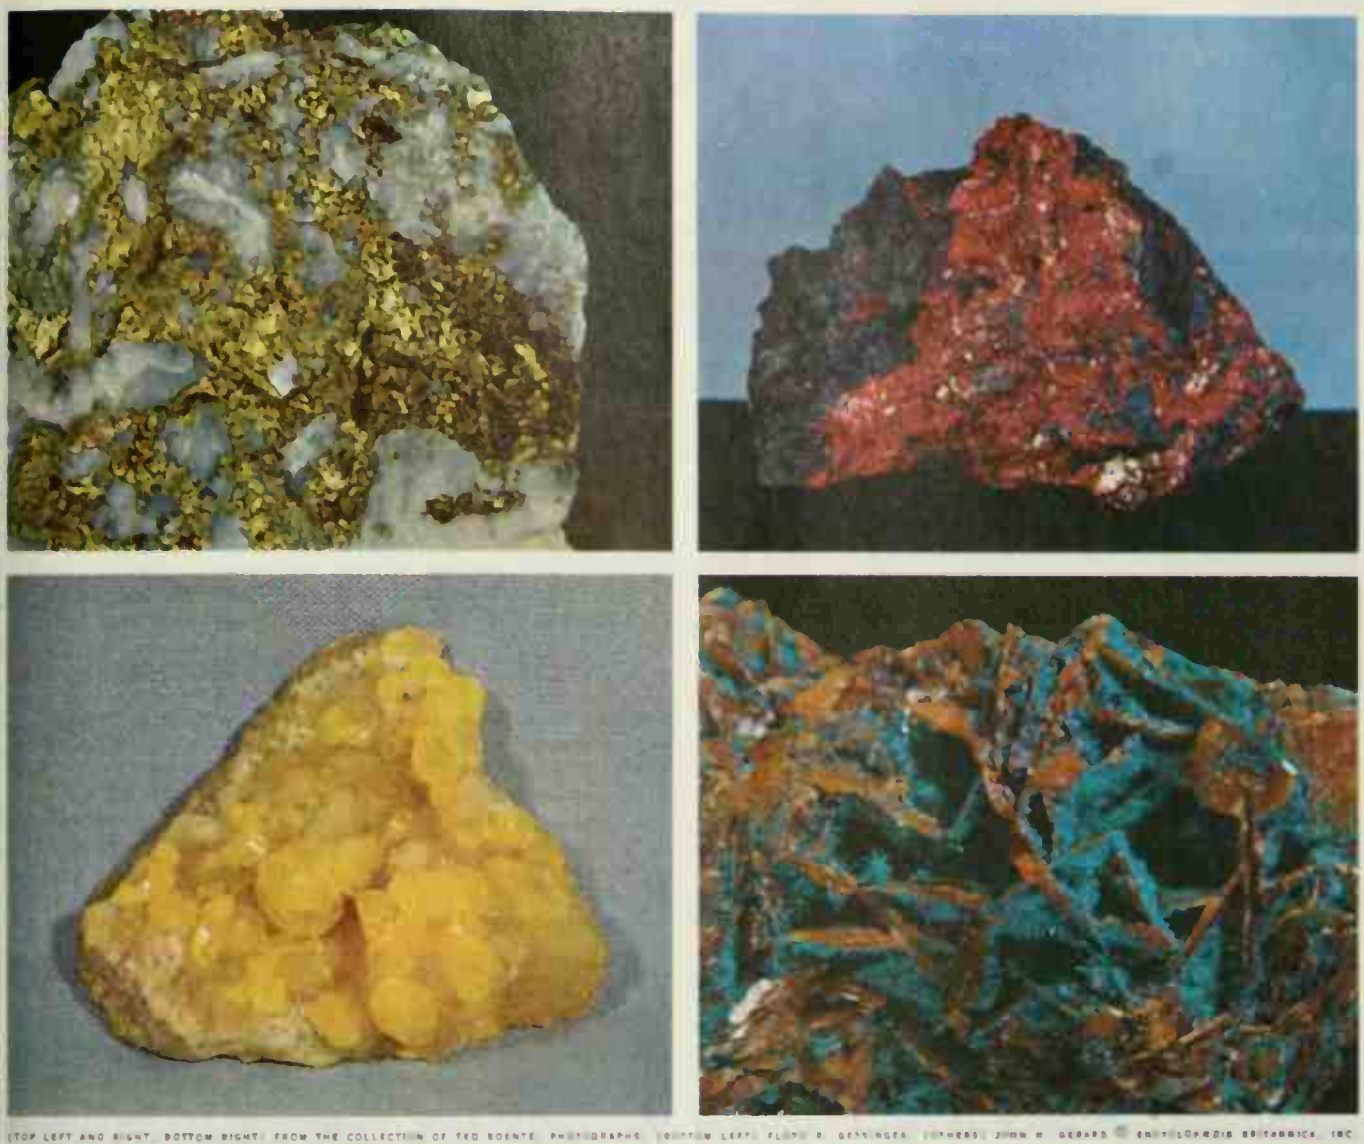
**Density.**—Density (mass per unit volume of a substance) depends upon the number, atomic weights, and compactness of arrangement of the constituents and is a characteristic property of a mineral species. Solid-solution series exhibit ranges in density dependent upon the composition; in fact, the composition of certain minerals (*e.g.*, gold, sphalerite) can be determined with fair precision from density measurement. Densities generally are measured as specific gravity (ratio of the density of a substance to that of water at 4° C. and 1 atm.) by means of the Jolly balance (for samples of a few grams), Berman balance (for milligram samples), pycnometer (for granules and powder) and various heavy liquids.

Heavy liquids (*e.g.*, mixtures of acetone and acetylene tetrabromide ranging up to a specific gravity of 2.9) are much used in the "sink-float" separation of mineral powders for chemical analysis and other purposes. (*See* also PETROLOGY: *Methods of Investigation.*)

**Crystal Morphology.**—Minerals occurring in euhedral (completely bounded by faces) or subhedral (partly bounded by faces) crystals can be identified, in



(TOP LEFT AND RIGHT, BOTTOM RIGHT) FROM THE COLLECTION OF TED BOEHTE. PHOTOGRAPHS (BOTTOM LEFT) FLOYD P. GIBBONS (TOPMOST) JOHN H. GERARD © ENCYCLOPÆDIA BRITANNICA, INC.

FIG. 7.—EXAMPLES OF MINERALS IN WHICH THE COLOUR IS AN INTRINSIC PROPERTY OF THE SPECIES

(Top left) brass-coloured chalcopyrite, $CuFeS_2$, from Ontario, Canada; (top right) red cinnabar, HgS, from Arkansas; (bottom left) yellow sulfur, S, from Racalmuto, Italy; (bottom right) green dioptase, $Cu_6(Si_6O_{18})\cdot 6H_2O$, with orange-yellow wulfenite, $PbMoO_4$, from Arizona

principle, by their interfacial angles and symmetry, accurate determination of which requires use of the optical goniometer ("angle measurer"). Goniometry was formerly an important method of identification but has been largely supplanted by more powerful straightforward methods. Simple observation of crystal habit, nonetheless, is useful in the recognition of many minerals. It may be made megascopically or by optical and electron microscopy.

**X-ray Diffraction.**—X-ray diffraction effects in minerals are observed by several different techniques (*see* X-RAYS). Most extensively used is the powder (Hull-Debye-Scherrer) method in which the diffraction pattern produced by a minute sample of fine powder is recorded as a series of curved lines on a strip of film. Each crystalline species is characterized by a particular set of lines having certain spacings and intensities.

The method provides not only an extremely effective "finger print" for identification, but also yields information about homogeneity, composition, symmetry, unit cell, crystallinity and grain size. The powder and the related recording diffractometer methods are essential for the investigation of fine-grained minerals such as serpentines and clays.

The single crystal techniques (oscillation, rotation, Weissenberg and precession methods) are used chiefly for the determination of unit-cell dimensions and shape, space group, special twin laws, crystal structure determinations and various structural details.

**Optics.**—The interaction of light, that is, electromagnetic radiation in the visible region (4,000 to 7,500 Å), with crystalline matter provides another important class of properties. Minerals in which the bonds have significant metallic character absorb some and reflect the rest of the incident light; they are opaque and have a metallic lustre. Minerals whose bonds do not have appreciable metallic character can transmit light and are characterized by a nonmetallic lustre. A few minerals, however, have intermediate character and submetallic lustres. The optical properties of minerals with metallic lustre have to do mainly with the behaviour of reflected light. The colour of smooth fresh surfaces of such minerals depends largely on the principal constituents and is, therefore, a useful determinative property. (*See* fig. 7.) However, the true colour of many surfaces is camouflaged by tarnish (notably bornite), an extremely thin film of alteration product. The optical properties of opaque minerals are best observed on polished surfaces by means of the polarizing reflecting microscope.

The optical properties of the nonmetallic minerals depend mainly upon the behaviour of the transmitted light. However, the most obvious such property, colour, is much more variable than is the case for the metallic minerals. Although many nonmetallic minerals do have an intrinsic colour (sulfur, rhodonite, azurite), most do not (quartz, fluorite, beryl, celestite), and their colours, if any, depend on finely dispersed impurities, intergrown phases, state

FROM THE COLLECTION OF JOSEPH AND HELEN GOETTELMAN. PHOTOGRAPHS JOHN H. GERARD & ENCYCLOPAEDIA BRITANNICA, INC.

FIG. 8.—EXAMPLES OF MINERALS IN WHICH THE COLOUR IS NOT AN INTRINSIC PROPERTY OF THE SPECIES. COLOUR IN SUCH MINERALS VARIES BECAUSE IT IS CAUSED BY IMPURITIES. VARIATION IN SOLID-SOLUTION COMPOSITION AND STRUCTURAL IMPERFECTIONS THAT CAN DIFFER FROM SPECIMEN TO SPECIMEN AND EVEN WITHIN SMALL SINGLE CRYSTALS

(Top, from left) fluorite, $CaF_2$: green from England and yellow, colourless and purple from Rosiclare, Ill. The pieces are single crystals bounded mainly by cleavage surfaces. (Bottom, from left) beryl, $Be_3Al_2Si_6O_{18}$, from Brazil. Specimens on extreme right and left are gem varieties commonly referred to as aquamarine. Piece at centre left is common green beryl. Large pink crystal at centre right is a gem known as morganite or rose beryl. All are single euhedral crystals

of aggregation, imperfections such as colour centres, fracture and cleavage, and nature of the surface (*see* fig. 8). The colours, and even lustres, of many minerals having extensive solid solution (amphibole, olivine, wolframite) commonly show considerable range and can be of value in indicating approximate composition. The optical properties of crystals are vectorial, that is, depend upon direction. The repetitive arrays of atoms set up fields which polarize the transmitted visible electromagnetic radiation (*see* LIGHT).

The fields in minerals having isometric symmetry cause isotropic behaviour of light (same in every direction). For all others the fields cause anisotropic behaviour, the optical symmetry being controlled by the atomic structure. Optical behaviour is observed and measured by the polarizing or petrographic microscope. Even colour is vectorial and except for isotropic minerals, any colour absorption present varies with direction (pleochroism). The most fundamental optical properties are refractive indices (relative velocity of light in the substance to that in air—strictly speaking, to that in a vacuum), optic symmetry and orientation. For a given direction of light vibration the refractive index varies with the wave length (and slightly with temperature). The difference in refractive index for light of different specified wave lengths (e.g., that of the hydrogen C, 6563 Å, and hydrogen F, 4861 Å, lines) is termed the dispersion and is a fundamental property of the substance. In ordinary work refractive indices are measured with respect to white light, which gives values approximating those for the sodium D line (5893 Å).

Isotropic minerals are characterized by a single refractive index (with respect to a particular wave length or to white light) and a particular dispersion. Anisotropic minerals are of two kinds: uniaxial crystals (tetragonal and hexagonal) characterized by two, and biaxial crystals (orthorhombic, monoclinic and triclinic) characterized by three principal refractive indices, accompanying dispersions, and vibration directions whose orientations are limited by the crystal symmetry.

Derivative optical properties much used in mineral determination are birefringence (difference between the maximum and minimum indices), optic angle and sign, and extinction angle. Optical properties provide information about solid-solution composition as well as about the identification of species. Mineral optics are measured in thin sections and in crushed grains immersed in oils of known refractive indices.

Although the obvious gross optical properties (*e.g.*, varieties of nonmetallic lustre, transparency, colour, streak and iridescence) are sufficiently characteristic to aid in the identification of many species and varieties, they are likely to vary in unpredictable ways due to impurities, mineral intergrowths, nature of the surface, fractures and state of aggregation. Streak, the colour of the fine powder obtained by rubbing a mineral against unglazed porcelain, is the most useful colour-based property.

**Cohesion.**—Properties such as hardness, cleavage, parting, fracture, flexibility, elasticity, tenacity, glide, percussion figures, etch figures and corrosion forms depend upon the cohesion of the constituent atoms. Of these, hardness and cleavage are of the most use in identification. The others are distinctive only for certain species.

Mineral hardness is conventionally measured as the resistance to scratching (resistance to indentation is sometimes used in the microscopic study of ores) in comparison to an arbitrary reference scale, the Mohs' scale (*q.v.*) of hardness. Mohs' scale arranges a standard series of minerals in order of increasing relative hardness as follows:

| | |
|---|---|
| 1. Talc | 6. Microcline (or orthoclase) |
| 2. Gypsum | 7. Quartz |
| 3. Calcite | 8. Topaz |
| 4. Fluorite | 9. Corundum |
| 5. Apatite | 10. Diamond |

Hardness is vectorial although this is not usually apparent from the crude method of measurement used in determinative work. Hardness anisotropism is, however, very marked for kyanite; it is 4 to 5 parallel to the *c* axis and 6 to 7 perpendicular to it.

Cleavage, the property of breakage along planar surfaces in rational crystallographic directions, is controlled by the crystal structure and bonding. When present, it is characteristic of the mineral species and, consequently, is a useful diagnostic property.

**Magnetism and Electricity.**—A great many minerals are at-

FIG. 9.—SPECIMEN (FROM FRANKLIN, N.J.) OF CALCITE, $CaCO_3$, WITH GRAINS OF BLACK FRANKLINITE, $(Zn,Mn,Fe)(Fe,Mn)_2O_4$, AND VEINS AND GRAINS OF BROWNISH GOLD WILLEMITE, $Zn_2SiO_4$

(Top) specimen in ordinary light. (Bottom) fluorescent colours due to excitation by ultraviolet light (*see* text). Red is calcite, green is willemite, black is nonfluorescent franklinite

tracted by the poles of a strong electromagnet, that is, they are paramagnetic. Each such species is characterized by a particular magnetic susceptibility (or range of susceptibility), a property useful in the electromagnetic separation of fine-grained and intimately intergrown mixtures of rock and ore minerals for chemical analysis and other study. A very few minerals (magnetite, ilmenite, pyrrhotite) are ferromagnetic (having susceptibilities several orders of magnitude greater) and are attracted by an ordinary hand magnet. Still others (zircon, calcite) are diamagnetic and are repelled by a strong electromagnet.

Although electrical properties are rarely used in determinative work certain ones are important in the investigation of the nature of minerals and in technology. Minerals having metallic lustres are good conductors or semiconductors, while those having nonmetallic lustre are nonconductors (they are dielectric). Dielectric behaviour is receiving increasing attention in the investigation of the nature of minerals. Dielectric crystals not possessing a centre of symmetry exhibit piezoelectricity, whereby electrical charges develop upon the application of pressure. The property is used in the production of pressure gauges (tourmaline) and oscillators (notably quartz).

**Heat.**—Thermal properties include melting and inversion points, thermal conductivity, diathermancy (transparency to infrared radiation), thermal expansion, specific heat (or heat capacity) and the various heats of reaction, formation, solution, crystallization (latent heat of fusion), inversion and hydration. These properties are not used directly for determinative purposes, although the combined effects of several are involved in the property of fusibility and in the method of differential thermal analysis (DTA). Fusibility (a function of melting temperature and viscosity of the melt) ranges from that of stibnite (melting to a globule in a candle flame) to that of quartz (infusible in an ordinary blowpipe flame); it is diagnostic for a few minerals. Differential thermal analysis determines, for samples being heated up at a controlled rate, the intensities of and the temperatures at which thermal effects occur. The effects accompany compositional and structural changes (dehydration, oxidation, reaction, inversion, loss of crystallinity) during heating; they may be endothermic (absorb heat) or exothermic (give up heat to their surroundings). The thermal behaviour is recorded graphically (DTA curve) and is a characteristic property of many minerals. The shape of the curve depends on the various heats of hydration, reaction, inversion and crystallization of the mineral sample and also upon the instrumentation and procedure. The method is invaluable for the identification of many fine-grained minerals such as the clays; it is finding increasingly wide application to many others, including carbonates, hydroxides and hydrous oxides, and sulfides.

**Luminescence and Radioactivity.**—Luminescence (*q.v.*), the emission of visible light in response to excitation from an external source, is useful in the search for and identification of a number of minerals. Fluorescence is the variety of luminescence resulting from excitation by ultraviolet and shorter wave-length radiation. (*See* fig. 9.) The colour of fluorescence varies with impurity composition; a semiquantitative estimation of the molybdenum content of scheelite, $Ca(W,Mo)O_4$, for example, can be made by means of the fluorescent colour. Thermoluminescence (fluorite) results from thermal excitation. Triboluminescence (fluorite, sphalerite) arises from mechanical excitation by rubbing or scratching.

The radioactivity (*see* RADIOACTIVITY) associated with uranium and thorium containing minerals is an essential aid in the search for sources (*e.g.*, uraninite, carnotite, monazite) of nuclear energy. It is detected and measured mainly by Geiger and scintillation counters. Radioactivity is indicated in thin sections of rock by discoloured spots (pleochroic haloes) around tiny grains (zircon, allanite, thorite) enclosed in minerals such as biotite, muscovite and cordierite. The crystal structures of such tiny grains are commonly destroyed (metamict state) by the long-continued high-energy bombardment.

Several methods of measuring geologic time depend upon the radioactivity of minerals. The more reliable ones are based on the abundance ratios of isotopes (*e.g.*, lead-206/uranium-238, lead-204/lead-207, strontium-87/rubidium-87, argon-40/potassium-40) connected with the radioactive decay. The ratios are measured by mass spectroscopy (*q.v.*).

## V. GEOLOGIC OCCURRENCE AND ORIGIN

Minerals are the products of the geological processes and as such provide evidence leading to knowledge about these processes and about the evolution of the earth. Interpretation of the evidence, however, is a difficult and far from straightforward matter on account of the extreme complexity of the processes and because many of them operate under environmental conditions and durations of time far removed from our ordinary experience. Consequently, not only do a great many challenging problems remain to be satisfactorily explained but many of the genetic explanations already proposed are working hypotheses or trial models rather than proven fact. They are undergoing continual improvement or are being supplanted by alternative models. Consult the articles GEOCHEMISTRY; GEOLOGY; and ORE DEPOSITS for additional information about geological processes and occurrences of minerals. A further consideration to be kept in mind is that mineral evolution is a dynamic process—geologic environments undergo continual change in geologic time and mineral assemblages tend to change in response to the changing conditions.

**Igneous Rocks.**—The great bulk of the earth's crust is composed of generally massive aggregates of rock-forming minerals termed igneous rocks. The most abundant and characteristic minerals (essential ones) are feldspars, quartz, micas, amphiboles, pyroxenes, olivine, serpentines and feldspathoids. Igneous rock classifications are based largely upon the proportions of these minerals and upon the texture of the aggregate. Small amounts of accessory minerals are also present (*e.g.*, sphene, ilmenite, magnetite, zircon, allanite, apatite, fluorite and xenotime).

The problem of the origin of igneous rocks is still far from settled. Volcanic rocks can be observed to form by the crystallization of lava, a complex solution-melt (magma) of silicate, common metallic elements, small amounts of water and traces of many other constituents that have been erupted at the surface. The chemically and mineralogically analogous coarser-grained plutonic (deep-seated) rocks, however, form in regions inaccessible to observation and under extremely complex conditions. General agreement as to their origin has not been reached. Many geologists believe that all igneous rocks are magmatic (of molten origin) and that the plutonic ones are deeper-seated equivalents of volcanic rocks. Others believe that at least some plutonic rocks have formed by the transformation of pre-existing rocks without the agency of magma, by a process akin to extreme metamorphism. It is likely that both magmatic and transformational processes are operative in the crust, depending upon the conditions prevailing. *See also* PETROLOGY.

**Metamorphic Rocks.**—Metamorphic rocks are so varied that only a slight indication of the possible mineralogical combinations can be given. The gneisses and schists typical of regionally metamorphosed terrains are composed chiefly of quartz, micas, and feldspar. Many varieties contain minerals such as garnet, staurolite, chlorite, epidote, amphibole and ferroan dolomite (ankerite) with or in place of some of the first listed ones. Typical accessories are sphene, tourmaline, ilmenite, apatite, magnetite and rutile. Slates are composed of extremely fine-grained quartz and micalike and chloritic minerals intermediate to those in shales and in schists; marbles consist of calcite and dolomite; and quartzite almost entirely of quartz. Contact metamorphic rock (tactite or skarn) is composed of various combinations of characteristic and often beautifully crystallized garnet, epidote, idocrase, wollastonite, diopside-hedenbergite, tremolite-actinolite and calcite or dolomite.

Metamorphism is the transformation (without melting) of pre-existing rocks in response to changes in the temperature, pressure and composition. The transformations range from recrystallization of the original minerals (marble and quartzite) to complete changes in mineralogy, texture and structure. Some transformations also involve considerable change in bulk chemical composition, or metasomatism (*q.v.*). The intensity of the metamorphic

conditions appears to be reflected by the production, for a given bulk composition, of characteristic mineral assemblages (metamorphic facies). *See* also METAMORPHISM.

**Sedimentary Rocks.**—Sedimentary minerals include carbonates (calcite, siderite), sulfates (gypsum, anhydrite), phosphates (apatite), halides (halite), oxides (hematite, diaspore) and sulfides (pyrite), as well as the silicates. Many of them (notably the clays) are extremely fine-grained (*e.g.*, less than 2 microns, or 0.00008 in.) and commonly are poorly crystallized. Identification and knowledge about the nature of these has been possible only through the application of techniques such as X-ray diffraction, electron microscopy and differential thermal analysis.

Sedimentary rocks are formed at or near atmospheric conditions from the materials of pre-existing rocks (igneous, metamorphic or older sediments). Minerals such as quartz, and to a lesser extent ilmenite, garnet and zircon, are resistant to weathering and transport and thus survive in clastic (fragmental) sediments. Fragments of pre-existing rocks may also survive under certain conditions. Other minerals such as illite, montmorillonite and clay-chlorite, although inherited from the parent material, may be more or less reconstructed in the sedimentary environment. Still others (*e.g.*, calcite, halite, gypsum) form completely anew in the environment. Organic agents also participate in the formation of sedimentary minerals. Much of the calcite in limestones is produced originally by organisms such as algae, corals and brachiopods; quartz in many cherts commonly originates from opal (amorphous $SiO_2$) deposited by diatoms and radiolaria.

Ancient sediments generally are consolidated. Some of the more common types are: shale (illite, clay-chlorite, quartz, montmorillonite, organic matter), sandstone (largely quartz), graywacke (quartz, feldspar, micas and micalike clays, chlorite, rock fragments) and limestone (largely calcite). Evaporites are composed mainly of gypsum or anhydrite, commonly with interbedded halite, and less so with sylvite, carnallite and other highly soluble minerals. Recent sediments generally are unconsolidated. They are being intensely investigated in order to obtain mineralogical criteria for sedimentary environments and evolution. *See* also SEDIMENTARY ROCKS.

**Mineral Deposits.**—Mineral deposits include those mineralogic bodies that do not compose a significant part of the earth's crust (*i.e.*, those other than rocks). Their minerals include representatives from every class and they occur in a great variety of ways, such as veins and veinlets, irregular replacement masses, cavity linings, beds and disseminations in rock. Most have no economic value; those that do are ore deposits. Typical ore minerals are galena, chalcocite, hematite and pyrite containing gold. Those not having an economic value (as quartz, jarosite, siderite) are gangue minerals.

Mineral deposits probably form most commonly by deposition from solution. Deposits such as calcite veins in limestones, barite in sediments, bog iron (mainly goethite) and many bodies of quartz have been deposited by ground water at ordinary temperatures. Others, including most metalliferous ore deposits, have formed at elevated temperatures. They are generally surrounded by alteration zones, which may extend into the host rock for tens or hundreds of feet. Mineralogical study of these alteration zones is increasingly important in the search for ore deposits. Mineral deposits also form by sedimentary, metamorphic and igneous processes.

## VI. EXPERIMENTAL MINERALOGY

A notable feature of modern mineralogy is the extensive and fruitful use of experimental methods to supplement field and laboratory methods in the endeavor to understand the extraordinarily complex processes of mineral genesis. Common approaches include geochemistry, mineral synthesis, phase equilibria studies, experimental simulation of geological processes and investigation of mineral properties under different conditions.

Almost all the common minerals and a great many rarer ones have been synthesized by one means or another. Synthesis of individual minerals, however, generally is of limited direct application to mineral genesis. On the other hand, it is an important source of technologically useful substances (such as industrial diamonds, corundum and cubic boron nitride for abrasives; quartz for oscillators; soda niter for polarizing prisms); and for gem materials (such as ruby, star sapphire and iron-free rutile, or titania). The principal techniques are: precipitation from solution (yielding fine-grained products), crystal growth from solution (from seed crystals), crystallization from a melt, flame fusion (the Verneuil process), solid-state reactions and phase transformations, crystallization and reaction from vapour, and hydrothermal synthesis.

Phase equilibria studies of simplified analogues of geological systems are of particular importance in furnishing fundamental knowledge about mineral formation. They are also of great technological value (*e.g.*, in smelting, manufacture of ceramic and refractory bodies, cement production). Inasmuch as mineral stabilities are influenced by the presence of different components, studies of multicomponent systems are the most informative. One of the earliest major contributions was J. H. van't Hoff's investigation (1896) of saline solutions (at ordinary temperatures and pressures) and its application to the formation of evaporites such as those at Stassfurt. The most notable of all has been the meticulous and comprehensive program at the Geophysical laboratory of Washington, D.C. Following Bowen's classic study (1913) of the plagioclase binary system and its solid solution (*see* FELDSPAR), equilibrium relations of the mineral phases of a great many systems have been determined at high temperatures (and atmospheric pressures). Such work led Bowen to his fundamental reaction principle (*see* GEOCHEMISTRY: *Geochemistry of the Lithosphere: The Reaction Series*). R. W. Goranson's study (1931) of water-containing silicate systems at high temperatures and pressures showed that melts dissolve several per cent of water and that melting temperatures of minerals under these conditions are considerably lower than in the analogous anhydrous systems. With the availability of more practicable apparatus, Bowen and O. F. Tuttle (1949) stimulated systematic hydrothermal investigation analogous to the earlier work on anhydrous systems. More recently, the "simple squeezer" apparatus of D. T. Griggs and G. C. Kennedy has enabled the determination of mineral stabilities to at least 50,000 atmospheres and close to 1,000° C. These investigations reveal that, in the presence of water (and other volatiles) under high confining pressures, mineral reactions occur rapidly even at temperatures of only a few hundred degrees, temperatures at which a great many anhydrous systems show no appreciable reaction even during several months' time. This has made possible the observation of many hitherto unknown solid-state reactions. In addition to silicate studies, intensive investigation of carbonate and sulfide systems has been made. Besides the phase equilibria studies, methods for learning about geologic temperatures include use of the pressure-volume-temperature relations of liquid inclusions in minerals, isotopic ratios (*e.g.*, $oxygen^{16}/oxygen^{18}$ in quartz and in the calcite of shells) and the thermoelectric potential of pyrite (pyrite geothermometer). (*See* also SILICON; *The Silicates.*)

The investigation of the properties of minerals and aggregates under various conditions of temperature, pressure and stress is of considerable technological as well as some geological significance. Properties of interest are: refractoriness, shear strength, electrical conductivity, thermal expansion, viscosity of melts, resistance to abrasion, impact and seismic behaviour at high temperature and pressure. *See* CRYSTALLOGRAPHY; *see* also references under "Mineralogy" in the Index.

**MINERAL PHOSPHATES.** The element phosphorus is known to be present in more than 150 minerals most of which belong to the apatite family of calcium phosphates. (For varieties and chemical composition *see* APATITE.) Phosphorus, an essential constituent for all living organisms, is one of the least abundant of the mineral nutrients. Its average content in soils and rocks of the earth's crust is 0.12%, whereas iron is 5%, calcium is 3.6%, potassium is 2.6% and magnesium is 2.1%. Thus when phosphorus is removed from the soil by crops, it must be replaced artificially by adding phosphate fertilizers to soils. Phosphorus also is used widely in manufacturing industries. Nearly all of the phosphate fertilizers and phosphorus for industrial uses are obtained from naturally occurring rocks containing high concentrations of phosphate-bearing minerals. Thus the availability of large quantities of phosphate rock is of primary importance to agricultural and industrial nations.

**Uses.**—Within the United States about 60% of all phosphate used, and in other countries a larger percentage, is for agricultural purposes, and most of this is made into fertilizers. The remaining production is used in making elemental phosphorus and phosphoric acid. These products are made into organic and inorganic chemicals to be used in preparing detergents, water softeners, leavening agents (cooking), plasticizers, insecticides and many other products. Elemental phosphorus also is used in military smoke screens and incendiary bombs, phosphorus alloys and pesticides. In addition phosphoric acid is made into fertilizers, animal-feed supplement, beverages, photographic supplies, dental and silicate cements, ceramics, and is used as a catalyst and oil-refining agent. A complete list of phosphate compounds would embrace almost every manufacturing process and nearly all chemical techniques.

**Principal Types of Phosphate Deposits.**—Primary, or original, phosphate deposits are: apatite-bearing igneous rocks, marine sedimentary rock phosphorites and phosphatic shales and limestones, and guano. These deposits may give rise by geological processes of erosion and deposition to secondarily enriched deposits known as: residual phosphorites, river-pebble phosphates and phosphatized rock.

Igneous apatite deposits are formed as a result of differentiation of the constituents of cooling magmas (molten rock material) which have been intruded into rocks of the earth's crust. These deposits are sheetlike or irregular masses associated with other types of igneous rocks and may contain as much as 35% phosphorus pentoxide, designated in the fertilizer industry as $P_2O_5$ or as phosphoric acid. Although these deposits are of less importance than marine phosphate deposits, they have been the ultimate source of the phosphatic compounds in solution in sea water from which marine phosphate deposits have been derived.

Inorganic and/or organic processes, operating upon phosphoric acid in solution in sea water, precipitated the carbonate-fluorapatite minerals as blanketlike deposits of marine phosphorite and phosphatic shales and limestones on ancient sea floors. Marine phosphorites consist of layers of phosphatic pellets and nodules ranging from less than 0.1 to more than 20 mm. in diameter. Individual layers may be more than six feet thick and contain as much as 35% $P_2O_5$. Phosphorites are associated with black, carbonaceous, and phosphatic shale, chert and minor limestone. Phosphatic layers generally are thin, but the total thickness of such deposits may be many tens of feet. These deposits consist of a small percentage of phosphate pellets mixed with other sedimentary material such as clay, silt, sand and calcium carbonate. The phosphate content may range from 0% to 30%. Marine phosphate deposits contain reserves calculated to be of the order of several billions of tons. The marine phosphorites and phosphatic rocks contain many minor metals. Of these, vanadium is recovered from western U.S. phosphorite, and uranium is recovered from some Florida phosphates.

Guano (*q.v.*) deposits form by the accumulation of seafowl or bat droppings. The largest deposits are formed on islands in low latitudes along western margins of continents where phosphate-rich sea waters permit a luxuriant growth of marine organisms upon which seafowl feed and where a semiarid climate permits preservation of their excreta. Guano deposits generally are small; the larger contain a few millions of tons at the most. Guano ranges widely in composition, and the phosphatic content generally is less than 25%. The phosphatic minerals in the deposits include hydroxylapatite, carbonate hydroxylapatite, brushite (a hydrous phosphate) or monetite (an anhydrous phosphate).

Residual phosphate deposits develop by decomposition of phosphatic limestones located within humid climatic regions. These deposits, consisting of phosphate pellets and nodules left behind when the calcium carbonate of the limestone is removed by solution, lie on the irregular weathered bedrock surface. In hilly country the residual phosphate deposits are narrow and conform to the outcrop pattern of the strata, but in valleys or flat country the deposits are blanketlike. These deposits range in thickness from one to several tens of feet. The phosphate content varies from a few to about 30%. The higher-grade deposits are utilized directly but lower-grade deposits must be beneficiated (to remove worthless material) by washing, screening or flotation, in order to yield a salable product. Phosphate reserves of residual deposits amount to many millions of tons.

River-pebble deposits consist of phosphate pellets and nodules weathered out of marine phosphatic limestone, located in humid climatic regions of low relief. The pellets and nodules are reconcentrated by stream action. Most river-pebble deposits do not contain sufficient phosphate to be mined profitably, but those in Florida are mined and beneficiated cheaply enough to produce a commercial product. Phosphate reserves in river-pebble deposits range from a few thousand to many millions of tons.

Phosphatized rocks develop in regions of tropical and subtropical climate when phosphate dissolved from phosphatic rocks or guano by percolating water is reprecipitated in openings or replaces the minerals of limestone, igneous rocks or clay that lie at a lower horizon. Phosphatized rocks are not abundant but some contain as much as 30% to 35% $P_2O_5$, and reserves are estimated in thousands to millions of tons.

**Phosphate Deposits in the United States.**—Examples of all the principal types of phosphate deposits are present in the U.S. Although phosphate concentrations are known in 28 states, current production is confined to four large fields. These fields, listed in order of their total production are: (1) the land-pebble deposits of Florida, (2) phosphatized (hard-rock) deposits of Florida, (3) the residual (brown-rock) deposits of Tennessee and (4) the marine phosphorites and phosphatic shales of the western field (principally Idaho, Montana, Utah and Wyoming). These fields contain practically all of the minable phosphate rock reserves in the U.S. recoverable under economic conditions prevailing in the second half of the 20th century.

The land-pebble phosphates of Florida are blanketlike deposits covering about 2,600 sq.mi. of west-central Florida. These are a combination of residual and fluviatile concentrations of phosphate pellets and nodules derived from phosphatic limestone of the Hawthorn formation of Miocene age. The phosphate was reconcentrated as the Bone Valley formation of Pliocene age. The phosphate deposits range from 1 to 50 ft. thick and average 12 ft. The deposits consist of nearly equal amounts of phosphate pellets and nodules, sand and clay. The phosphate zone is overlain by as much as 60 ft. of overburden which is removed by large draglines before the phosphate is mined by similar methods. Phosphorite particles are beneficiated by washing, screening and flotation methods. The recovered product is sold according to its B.P.L. (bone phosphate of lime) content which is 2.18 times the $P_2O_5$ content.

The hard-rock phosphate deposits of northwestern Florida are of Pliocene age and also were derived by weathering of the Hawthorn formation. These deposits are small but some contain as much as 35% $P_2O_5$. They are mined and beneficiated by the same methods as are used in the land-pebble fields.

The Tennessee brown-rock or residual deposits, located in the

Mt. Pleasant region of Tennessee, have been derived from Ordovician age phosphatic limestones of the Hermitage, Bigbey and Leipers formations. The deposits conform closely to the outcrop pattern of the parent limestones on the rolling, hilly topography. The thickest phosphate deposits fill solution-enlarged joints (locally called cutters) in the phosphatic limestones. These deposits also are mined by open-pit methods and beneficiated to produce a marketable product.

The marine phosphorites and phosphatic shales of the western field are in the Phosphoria formation of Permian age. Phosphate rock is mined in Idaho, Wyoming, Montana and Utah by open-pit and underground methods. Minable layers range from 3 to 20 ft. in thickness and contain from 20% to 32% $P_2O_5$. Most of the reserves in this field will have to be mined by underground methods.

The United States is self-sufficient in phosphate and has sufficient phosphate reserves to last for many centuries even under conditions of increased production.

**Phosphate Deposits in Other Countries.**—The principal resources of phosphate rock outside the United States are North Africa (the former French section of Morocco, Tunisia, Algeria and the U.A.R.-Egypt), U.S.S.R., the islands of the Pacific and Indian oceans and Brazil. In addition to these there are many others which are little developed and about which not much is known. These deposits are of the same types described above for the United States.

**MINERAL WATERS** are waters that contain mineral salts (or sometimes gases) in solution in concentrations sufficient to provide special properties and taste. The waters usually contain the salts naturally but they may be added. Mineral waters have been used in the treatment of various illnesses since the dawn of time, especially at spas such as Baden-Baden, Ger., Bath, Eng., Hot Springs National park, Ark., and Spa, Belg. (*See* also SPRINGS: *Mineral Springs*.)

ETRUSCAN BRONZE STATUETTE OF MINERVA AS GODDESS OF WAR, 5TH CENTURY B.C. IN THE BRITISH MUSEUM, LONDON

**MINER'S PHTHISIS:** *see* PNEUMOCONIOSIS.

**MINERVA,** an Italian goddess of handicrafts who presided also over the professions and the arts. She is commonly identified with the Greek Athena (*q.v.*), and some scholars believe that she is not of native cult but is Athena introduced at Rome from Etruria. Indeed she is one of the Capitoline triad in association with Jupiter and Juno (*qq.v.*), traditionally introduced by the Etruscan kings, and it would be difficult to find traces of her cult at Rome before that time. Her name, on the other hand, is Italian, not Etruscan, and is connected with the roots in *mens*, "mind," and *memini*, "remember" (the archaic spelling is Menerva).

She had several temples at Rome. Besides her cult on the Capitoline she had an important shrine on the Aventine which was a meeting place for guilds of craftsmen, particularly dramatic poets and actors who made it their headquarters during the Second Punic War. A shrine on the Caelian was dedicated to Minerva Capta, probably in consequence of the destruction of Falerii in 241 B.C.

Her worship as a goddess of war encroached upon that of Mars (*q.v.*) and she is sometimes confused with Mars's cult partner Nerio (*see* BELLONA). The festival known as the Quinquatrus, falling on the fifth day after the Ides of March (*i.e.*, March 19), was originally a festival of Mars but was taken over entirely by Minerva, apparently from the coincidence that this was the founding day of her temple on the Aventine.

The festival eventually was extended over five days to include March 23, the Tubilustrium or purification of the trumpets. The fact that the tuba was used in military as well as religious ceremonies made this festival not inappropriate to a war deity, although it was probably not originally connected with Minerva. After the first day, which was devoted to a lustration of the arms announcing a new military season, the remaining four were given over largely to gladiatorial shows. The whole season was a school holiday. There was a festival called the lesser Quinquatrus celebrated on June 13, the feast day of the flute players, of whom Minerva was the patron deity.

The erection of a temple to her by Pompey out of the spoils of his eastern conquests shows that she was the bestower of victory like Athena Nike. Under Domitian, who claimed her special protection, the worship of Minerva attained its greatest vogue in Rome. His forum (dedicated as the Forum of Nerva) was dominated by a temple of Minerva, and he built a second shrine to her in the Roman Forum.

*See* Platner-Ashby, *Topographical Dictionary*, *s.v.* "Minerva," "Jupiter Optimus Maximus" and "Forum Nervae." (R. B. Lr.)

**MING,** a major dynasty that governed China, 1368 to 1644, providing an interval of native rule between eras of Mongol and Manchu dominance. The dynastic name means "bright." The dynastic capital was Nanking through 1420 and Peking thereafter.

The Ming emperors reigned over a unified China that included Manchuria and at times extended into Vietnam on the south and to Hami in Chinese Turkistan on the west. Their armies campaigned through Mongolia almost to Lake Baikal, through Manchuria to the Amur river in Korea, in Vietnam and in Burma; and their fleets roamed Indonesian waters and the Indian ocean almost to Zanzibar. The rulers of Korea, Mongolia, Chinese Turkistan, Burma, Siam and Vietnam regularly acknowledged Ming overlordship, and at times tribute was received from as far away as Japan, Java and Sumatra, Ceylon and south India, the east African coast, the Persian gulf region and Samarkand. Modern Chinese honour the Ming rulers especially for having restored China's international power and prestige, which had been in decline since the 8th century. They probably exercised more far-reaching influence in east Asia than any other native rulers of China, and their attitude toward the representatives of modern Portugal, Spain, Russia, Britain and the Netherlands, who appeared in China before the end of their dynasty, was a condescending one.

The Ming state included several notable new institutions: the grand secretariat (*Nei-ko*), provincial governors (*Hsun-fu*) and viceroys (*Tsung-tu*), and the *pao-chia* system of local organization and surveillance. The government was unusually stable but was gradually undermined by epidemic factionalism among civil officials, corrupting interference by palace eunuchs and a succession of weak and inattentive emperors.

The dynasty encompassed the reigns of 16 emperors:

1. Chu Yuan-chang (1328–98), reigned 1368–98; reign title Hung-wu; temple name T'ai-tsu.
2. Chu Yun-wen (1377–?), grandson of T'ai-tsu, reigned 1398–1402; reign title Chien-wen; temple name Hui-ti.
3. Chu Ti (1360–1424), son of T'ai-tsu, reigned 1402–24; reign title Yung-lo; temple name Ch'eng-tsu.
4. Chu Kao-chih (1378–1425), son of Ch'eng-tsu, reigned 1424–25; reign title Hung-hsi; temple name Jen-tsung.
5. Chu Chan-chi (1398–1435), son of Jen-tsung, reigned 1425–35; reign title Hsuan-te; temple name Hsuan-tsung.
6. Chu Ch'i-chen (1427–64), son of Hsuan-tsung, reigned 1435–

49, reign title Cheng-t'ung; restored 1457–64, reign title T'ien-shun; temple name Ying-tsung.

7. Chu Ch'i-yu (1428–57), brother of Ying-tsung, reigned 1449–57; reign title Ching-t'ai; temple name Ching-ti.

8. Chu Chien-shen (1447–87), son of Ying-tsung, reigned 1464–87; reign title Ch'eng-hua; temple name Hsien-tsung.

9. Chu Yu-t'ang (1470–1505), son of Hsien-tsung, reigned 1487–1505; reign title Hung-chih; temple name Hsiao-tsung.

10. Chu Hou-chao (1491–1521), son of Hsiao-tsung, reigned 1505–21; reign title Cheng-te; temple name Wu-tsung.

11. Chu Hou-tsung (1507–66), cousin of Wu-tsung, reigned 1521–66; reign title Chia-ching; temple name Shih-tsung.

12. Chu Tsai-kou (1537–72), son of Shih-tsung, reigned 1566–72; reign title Lung-ch'ing; temple name Mu-tsung.

13. Chu I-chun (1563–1620), son of Mu-tsung, reigned 1572–1620; reign title Wan-li; temple name Shen-tsung.

14. Chu Ch'ang-lo (1582–1620), son of Shen-tsung, reigned only one month in 1620; reign title T'ai-ch'ang; temple name Kuang-tsung.

15. Chu Yu-chiao (1605–27), son of Kuang-tsung, reigned 1620–27; reign title T'ien-ch'i; temple name Hsi-tsung.

16. Chu Yu-chien (1611–44), brother of Hsi-tsung, reigned 1627–44; reign title Ch'ung-chen; canonized by Manchus as Chuang-lieh-ti, by various Ming loyalists as Ssu-tsung, Huai-tsung and I-tsung.

The founder of the dynasty, T'ai-tsu, was one of the strongest and most colourful personalities of Chinese history. His 30-year reign established the governmental structure, policies and tone that characterized the whole dynasty.

T'ai-tsu left his throne in 1398 to a grandson, Hui-ti. In trying to assert central control over the government, Hui-ti provoked a rebellion on the part of his uncle the prince of Yen and was overwhelmed in 1402. The prince of Yen, posthumously titled Ch'eng-tsu, took the throne for himself and proved even more ambitious and aggressive than T'ai-tsu. He subjugated Annam (north Vietnam), personally campaigned against the reorganizing Mongols in the north and sent naval expeditions overseas, chiefly under the eunuch Cheng Ho, to demand tribute from rulers as far away as Africa.

For a century after Ch'eng-tsu the empire enjoyed peace, stability and prosperity. State administration began to suffer from corrupt domination by eunuchs—Wang Chen in the 1440s, Wang Chih in the 1470s and 1480s and Liu Chin from 1505 to 1510. But Jen-tsung, Hsuan-tsung and Hsiao-tsung were model Confucian rulers—unaggressive, benevolent, trustful of their civil ministers. The only serious disruption of the peace occurred in 1449 when Wang Chen led Ying-tsung into a disastrous military campaign against the Oirats (western Mongols). The Oirat leader Yesen ambushed the imperial army, captured the emperor and besieged Peking. The defense minister Yu Ch'ien forced him to withdraw unappeased and for eight years dominated the government with emergency powers. When the interim emperor, Ching-ti, fell ill in 1457, Ying-tsung was restored, having lived in retirement after being released by the Mongols in 1450. Yu Ch'ien was then executed as a traitor.

Wu-tsung and Shih-tsung were probably the least capable Ming emperors. Wu-tsung was an adventure-loving carouser, Shih-tsung a lavish patron of Taoist alchemists. For one period of 20 years, during the regime of the unpopular grand secretary Yen Sung, Shih-tsung withdrew almost entirely from governmental cares. Both emperors cruelly humiliated and punished hundreds of officials for their temerity in remonstrating.

China's long peace ended in Shih-tsung's reign. The Oirats, under the vigorous leadership of Anda (Altan), were a constant threat on the north from 1542 on; in 1550 Anda raided the suburbs of Peking itself. Concurrently, Japan-based pirates plundered China's southeastern coast. Japanese piracy, a problem in the early Ming years, had been suspended in Ch'eng-tsu's time, when the Ashikaga shogunate offered nominal submission to China in exchange for trading privileges. But now the Japanese grew dissatisfied with the trading arrangements, and during the 1550s pirate fleets looted the Ningpo-Shanghai region almost annually, sometimes sending raiding parties as far inland as Soochow.

The Ming government was still able to respond vigorously when challenged. Chinese fleets crushed Japanese pirates in 1559 and 1561, and the coastal raiding ceased. Anda was repeatedly defeated in the 1550s and made peace in 1571. For the next decade, during the last years of Mu-tsung and the early years of Shen-tsung, the Ming state was probably at its peak of stability. The government was dominated by Chang Chu-cheng, the outstanding grand secretary of Ming history; and two generals, Ch'i Chi-kuang and Li Ch'eng-liang, maintained effective military defenses.

In 1592, when Japanese troops under Hideyoshi invaded Korea, Ming China was still strong and responsive enough to campaign vigorously in support of its vassal. But the Korean war dragged on indecisively until 1598, when Hideyoshi died and the Japanese withdrew. It made heavy demands on Ming resources and apparently precipitated a military decline in China.

The reign of Shen-tsung was a turning point of Ming history in other regards as well. Partisan wrangling among civil officials had flared up in the 1450s in reaction to Yu Ch'ien's dominance and again in the 1520s during a prolonged "rites controversy" provoked by Shih-tsung. After Chang Chu-cheng's death in 1582 it became the normal condition of court life. Through the remainder of Shen-tsung's long reign a series of increasingly vicious partisan controversies absorbed the energies of the officialdom, while the harassed emperor abandoned more and more of his responsibilities to eunuchs. The decline of bureaucratic discipline and morale continued under Kuang-tsung, whose sudden death after a reign of only one month in 1620 provoked new controversies. Hsi-tsung was too young and indecisive to provide leadership. In 1624 he finally gave broad powers to Wei Chung-hsien, the most powerful eunuch of Chinese history. Wei brutally purged hundreds of officials, chiefly those associated with a reformist clique called the Tung-lin party, and staffed the government with sycophants.

A new threat had meantime appeared on the northern frontier. The Manchus, quiet occupants of far eastern Manchuria from the beginning of the dynasty, in 1583 were aroused by an ambitious young leader, Nurhachi, and during Shen-tsung's latter years steadily encroached on central Manchuria. In 1616 Nurhachi proclaimed a new dynasty, and overwhelming victories over Ming forces in 1619 and 1622 gave him control of the whole northeastern segment of the Ming empire, down to the Great Wall at Shan-hai-kuan.

Chuang-lieh-ti tried to revitalize the deteriorating Ming government. He banished Wei Chung-hsien but could not quell the partisan strife that was paralyzing the bureaucracy. The Manchus, bypassing Shan-hai-kuan, repeatedly raided within the Great Wall, even threatening Peking in 1629 and 1638. Taxes and conscriptions became more and more oppressive on the Chinese population, and banditry and rebellions spread in the interior. The Ming government became completely demoralized. Finally a domestic rebel, Li Tzu-ch'eng, captured the capital in April 1644. Chuang-lieh-ti committed suicide. The Ming commander at Shan-hai-kuan accepted Manchu help in an effort to punish Li Tzu-ch'eng and restore the dynasty, only to have the Manchus seize the throne for themselves.

Ming loyalists ineffectively resisted the Manchu Ch'ing dynasty from various refuges in the south for a generation. Their so-called Southern Ming dynasty principally included the prince of Fu (Chu Yu-sung, reign title Hung-kuang, d. 1646), the prince of Tang (Chu Yu-chien, reign title Lung-wu, d. 1646), the prince of Lu (Chu I-hai, no reign title, d. 1662) and the prince of Kuei (Chu Yu-lang, reign title Yung-li, d. 1662). The loyalist sea raider Cheng Ch'eng-kung (Koxinga) and his heirs held out on Formosa until 1683.

Direct contact between China and modern Europe was established in Wu-tsung's reign, when in 1517 a Portuguese squadron under Fernão Peres d'Andrade landed at Canton. Despite Chinese hostilities and some persecutions, the Portuguese got a permanent trading base at Macao by 1557. Other Europeans soon joined in the China trade. Christian mission work began on the mainland in 1582 under Matteo Ricci and by the end of the Ming dynasty had won influence and converts even at the Peking court.

Chinese culture under Ming rule was distinguished more by productive competence than by creative brilliance. The period is specially known for architectural construction (Peking, the Great Wall), blue and white porcelain manufactures, prodigious scholarly production, the melodious *k'un-ch'u* form of opera, vernacular fiction (novels and short stories) and the idealistic philosophy of Wang Yang-ming (*q.v.*).

Ricci, *China in the Sixteenth Century*, trans. by L. J. Gallagher (1953). (C. O. HR.)

**MINGHETTI, MARCO** (1818–1886), Italian statesman, twice prime minister of Italy, was born in Bologna, then one of the Legations of the Papal states, on Nov. 8, 1818. A member of the constituent council summoned to Rome in 1847, he was minister of public works in the cabinet formed in March 1848; but after Pope Pius IX's allocution dissociating the papacy from the revolutionary movement in Italy, he resigned on May 1 and joined the Sardinian-Piedmontese army (*see* ITALIAN INDEPENDENCE, WARS OF). Returning to Rome in Nov. 1848, he refused to form a cabinet after the assassination of Pellegrino Rossi, to whom Pius had just entrusted the government. He then spent eight years in study and travel. In April 1859 Cavour appointed him secretary-general of the Piedmontese foreign office; and when the Legations of the Romagna rejected papal rule Minghetti was elected president of their assembly before their annexation to Sardinia-Piedmont.

Appointed minister of the interior under Cavour in Dec. 1860, a few weeks before the transformation of the kingdom of Sardinia into the kingdom of Italy (Feb. 1861), Minghetti retained the same office in the new kingdom till Sept. 1861. Having been finance minister under Luigi Farini from Dec. 1862, he became prime minister on March 24, 1863. With the help of Emilio Visconti-Venosta he concluded the convention of Sept. 15, 1864, whereby, in return for the withdrawal of French troops from Rome, it was agreed that the Italian capital should be moved from Turin to Florence. Since this implied abandonment of designs on Rome, Minghetti was driven from office eight days later.

Minghetti took little further part in public life till 1869, when he was minister of agriculture under Luigi Federico Menabrea. Both in and out of office, however, he exerted his influence against an alliance with France and in favour of an immediate advance on Rome. In 1870 the ministry of Giovanni Lanza and Quintino Sella sent him to London and to Vienna to organize a "league of neutrals" for the duration of the Franco-German War. Thanks to France's defeat, Rome at last fell to the Italians.

On the overthrow of the Lanza-Sella cabinet (July 10, 1873), Minghetti again became prime minister and minister of finance. Representing the right in Italian politics, he inaugurated a *rapprochement* with Austria as well as with Germany and succeeded in producing budgets without deficits for the first time since 1860, but took arbitrary measures against political opponents at home. Forced to resign on March 18, 1876, he opposed Agostino Depretis and the successive governments of the left till the development of *trasformismo* (*see* ITALY: *History*) reconciled him to them in the 1880s. Minghetti died in Rome on Dec. 10, 1886. His published works include his memoirs, *I Miei ricordi*, 3 vol. (1888–90).

**MINHO,** the province of northwestern Portugal, is known also as Aquem-os-Montes, in contradistinction to Trás-os-Montes, in the northeast. It was formed in 1936 from the northern part of the old Entre Douro e Minho province and comprises the administrative districts of Viana do Castelo and Braga. Pop. (1960) 899,773; area 1,368 sq.mi. The coastal plain forms a narrow belt about 70 mi. long and 2–10 mi. wide, narrowing north of the Lima valley, where the mountains of Santa Luzia (1,790 ft.) rise steeply from the coast. Most of the region consists of undulating granitic plateaus at an altitude of 300–750 ft., traversed by deep river valleys. From the Spanish frontier southward these rivers are: the Minho, Lima, Cávado and Ave, all flowing west-southwest. In the interior, the mountain ranges between the Minho and the Lima (Serra de Suajo 4,642 ft.) are continued by the Serra do Gerez (4,944 ft.) and the Serra das Alturas (4,150 ft.).

The climate is the most favourable for intensive agriculture in Portugal. Mean annual rainfall rises from 50 in. on the coast to more than 70 in. in the mountains. Winters are mild, although snowfall can be heavy in the eastern mountains. Water resources are good, notably on the Cávado (Vila Nova dam has an installed capacity of 156,000 kva.) and on the Lima (Lindoso dam).

The high population densities ranging from 500 to 700 per square mile explain the intensive cropping. Maize (corn) and haricot beans are important. A rapid succession of winter and summer crops is possible with intercultural planting; even the field borders are used for fruit trees and vines. The use of irrigation, the flights of terraces scaling the slopes and the marked dissemination of rural dwellings are all traits of this wooded landscape. Stock rearing is important on the higher lands and the timber industry is significant. Many of the ethnographic features are traceable to the Roman occupation and the ruins of the Celtic castros or hill forts are numerous.

Fishing is of local importance at Esposende, Viana do Castelo (pop. 14,371), Âncora-Gontinhaes and Póvoa de Varzim (pop. 17,314), ports all situated on the north side of the river mouths to avoid the sandbanks built up by longshore drift. Braga (*q.v.*), regional capital and seat of an archbishop, and Guimarães (pop. 23,233) are textile centres. (J. M. Ho.)

**MINIATURE LANDSCAPE.** The original form of Japanese miniature landscape was *hako-niwa* ("box yard"), a small landscape in a wooden box. It has not retained the popularity it still had at the dawn of the 20th century, which was equal to that now enjoyed by *bon-kei*.

*Bon-kei* ("tray landscape"), also known as *ban kei*, an evolution of *hako-niwa*, took on new life around 1900 when Izumi Chisen introduced *keto-tsuchi*, a sort of peat which was easy to model, as a substitute for earth. As *bon-kei* gained popularity many devices were tried, such as coloured earths, sand (representing water) and even newspaper soaked in water, which permitted landscapes to be made and remade quickly according to fancy.

*Sai-kei* (*sai*, "to plant trees or grass"; *kei*, "scenery") is the name of a movement started by *bon-sai* artists (who work with dwarfed trees); to give permanency to *bon-kei* they introduced natural instead of artificial stones and planted trees by the method called *toriki*. *Bon-kei* deteriorates with time, while *sai-kei*, made with living roots, improves with time. It seems appropriate to call such miniature landscapes *suibanmochi-no ishitsuki* ("*bon-sai* with roots having rocks").

*Bon-seki* ("tray stone") is the Japanese art of creating miniature landscapes on black lacquered trays with stones and sand, but without vegetation. Its origin is traced to the reign of Empress Suiko (593–628), when stones of rare shapes were presented to the court from China. Stones were appreciated for their solid reality and their unchanging character; it was believed they had the power to soften the hardened hearts of men. Later, sand was used with stones to suggest water and mountains. In a further development, stones were used to represent the sentiments of poems, or to reproduce famous natural or literary scenes. Brushes are used effectively, but plumes of different birds are indispensable in shaping the *bon-seki*. Stones of different shades are used according to different seasons. Already in vogue at the time of Ashikaga Yoshimasa (1436–90), *bon-seki*, like other forms of Japanese art, passed through different styles; a prominent school is Hosokawa-ryu, which was revived by the rare talent of its chief master, Katsuno Hakuyen.

Another way of enjoying stones, popular for centuries among the

Grove of 15 spruce trees all joined by a single root. Designed and executed by the Kato brothers

Another Kato design, a forest scene with 70 sprucs from a single root of a 15-year old tree. Almost 20 years of work were required to produce this sai-kei

ENGLISH, FRENCH AND AUSTRIAN MINIATURES

Japanese, is known as *sui-seki* ("water stone"). A natural stone of admirable shape is placed in a porcelain or bronze tray with sand and water. Months and years of patient watering and care may, according to the kind of stone used, bring forth a coating of moss, enlivening the stone with verdure like a mountain or like an island with forest and meadow. (J. HAR.)

**MINIATURE PAINTING.** This article is concerned with the history of the small, portable and finely wrought portraits known as miniatures. The name is derived from the minium, or red lead, which was used by the medieval illuminators for rubrication. In the 16th and 17th centuries the usual name for portrait miniatures was limnings.

**Origins.**—The heyday of the portrait miniature extended from the beginning of the 16th century down to the middle of the 19th century. The art owed its origin to the interest felt by the men and women of the Renaissance in personality and in its outward revelation by faithful and searching portraiture. This interest had already been seen in a small, intimate compass in the revival of the classical medal by Antonio Pisanello and his contemporaries of the 15th century. At the same time, the first portrait miniaturists continued with the technique of the illuminators of manuscripts (*see* ILLUMINATED MANUSCRIPTS), painting with detailed precision upon vellum with water colour and body colour. The miniature may therefore be said to have arisen from a fusion of the separate traditions of the illuminated manuscript and the medal.

The emancipation of the portrait miniature from the pages of the book, as a separate portrait enclosed in either a locket or a covered "portrait box," is most plausibly traced to the illuminators of Ghent and Bruges, of whom the most prominent were the Master of Mary of Burgundy, Simon Bening and Gerard Horenbout. However, the earliest datable portrait miniatures are not Flemish but French, and consist of a group of seven portraits representing the warrior companions of Francis I known as *Les Preux de Marignan* and found in the pages of an illuminated manuscript of about 1519. One or two of these were repeated separately as portrait miniatures properly so called; all are probably by Jean Clouet (*q.v.*), whose recognized work consists mainly of portrait drawings of men and women connected with the French court. His son, François Clouet (*q.v.*), succeeded him as painter to the French kings.

French miniature painting in the 16th century is not plentiful; it is closely connected with court circles, and what survives is the work of Jean and François Clouet and their close followers. The attribution of the miniatures generally follows that of the drawings on which they are based, and art historians often disagree about these. It is probable, however, that the miniatures of Catherine de Médicis and Charles IX at Vienna, the Catherine de Médicis in the Victoria and Albert museum, London, and the portraits of Mary Stuart and Charles IX, as a boy, in the English royal collection are by François Clouet. They agree in a certain hard brilliance, the slightly mechanical quality of which may be due to the fact that they are derived not from life but from drawings.

**England, 16th and 17th Centuries.**—Soon after Francis I had installed Jean Clouet as his painter, Henry VIII, in a spirit of emulation, encouraged Gerard Horenbout to come to England with his daughter Susanna and with Lukas Horenbout, who was probably her brother. Lukas Horenbout (d. 1544) painted the first portrait miniatures recorded in England. The portrait of Henry VIII at 35 in the Fitzwilliam museum, Cambridge, is probably by him, and some half dozen other works can plausibly be ascribed to the same hand. These first English miniatures combine the naturalism of the Flemish illuminators with a certain gravity of interpretation which was to pervade the national art till the end of the 17th century. Hans Holbein the Younger (*q.v.*), who was instructed in miniature painting by Lukas Horenbout, soon outstripped his master. He put into this small-scale work all the intensity of vision and fineness of touch apparent in his easel paintings and drawings, so that at the very beginning of the new art form masterpieces were created which have never been surpassed. His portrait of Mrs. Pemberton in the Victoria and Albert museum is the finest miniature ever painted. Barely a dozen authentic miniatures by Holbein are known, but they include one of Anne of Cleves, also in the Victoria and Albert museum, which is of great historical interest. This, with the panel in the Louvre, Paris, was the product of an official mission to Düren so that Henry VIII might decide on the basis of the portrait whether to marry the lady.

Nicholas Hilliard (*q.v.*), the first native-born master of miniature painting in England, modeled his technique upon that of Holbein and was the first artist to devote almost the whole of his working life to the miniature. Unlike his French contemporaries, Hilliard, who has left a fascinating account of his methods and ideals in his *The Art of Limning*, worked from life, and his portraits in consequence have a greater vivacity and freshness. He adopted the oval form which had recently become fashionable on the continent of Europe in preference to the circular form and which remained the most popular shape until the beginning of the 19th century. Hilliard's miniatures give the Elizabethan age in a microcosm and are imbued with the imagination and exuberance which pervaded all facets of life in those times. He was limner to Queen Elizabeth I for over 30 years and painted her portrait many times; he also painted Mary Stuart and many of the chief courtiers and adventurers, such as the earls of Cumberland and Leicester, Sir Francis Drake, Sir Walter Raleigh and Sir Christopher Hatton. The most famous of his pieces, "A Young Man Leaning Against a Tree Among Roses," is justly celebrated as a romantic interpretation of those romantic times. Hilliard emphasized line rather than gradations of tone in his drawing and modeling, and a bias toward this linear approach has persisted throughout English miniature painting.

Isaac Oliver (*q.v.*) was the chief pupil of Hilliard, and during the reign of James I he rose to enjoy more popularity than his master. His parents were fugitives from religious persecution in Rouen, and though he was probably only a baby when he was brought to England, Isaac Oliver always retained French sympathies. He traveled in the Low Countries and Italy; his style is more cosmopolitan than Hilliard's and characterized by more dramatic lighting. Isaac Oliver became a member of the household of Henry Frederick, prince of Wales; he was ably succeeded in his practice by his son Peter, who finished some of his father's works and made a series of small limned copies of oil paintings in Charles I's collection. John Hoskins (*q.v.*) continued in his early work the reticent manner of Hilliard, which was more attuned to the national temper. The effect of Van Dyck's sojourn in England from 1632 is clearly marked in all forms of English portraiture, and especially in the miniatures which Hoskins painted after this date. Samuel Cooper (*q.v.*), who was Hoskins' nephew and pupil, followed directly in this tradition. He is first discerned as an artist with an independent style shortly before 1640, and from then onward his miniatures show a penetration of character and a force of handling which account for his preeminent reputation throughout Europe. Horace Walpole justly said of him that "if a glass could expand Cooper's pictures to the size of Vandyck's, they would appear to have been painted for that proportion. If his portrait of Cromwell could be so enlarged, I don't know but Vandyck would appear less great by the comparison." Cooper's portrayal of the serious and self-reliant characters of the Commonwealth culminates in the sketch portrait of Oliver Cromwell (duke of Buccleuch's collection) to which Walpole refers. After the Restoration he showed himself equally capable of mirroring the pleasure-loving court of Charles II. His full-scale sketches of the famous beauties, Barbara, duchess of Cleveland, and Frances Stuart, duchess of Richmond, which are among his supreme achievements in this field, are in the royal collection at Windsor castle.

During the second half of the 17th century the other leading miniaturists were Thomas Flatman (*q.v.*), a pupil of Samuel Cooper, Nicholas Dixon (worked 1667–1708), a follower of Hoskins, and Lawrence Crosse (d. 1724), who embodies certain continental traits in his style of stippling, and whose work stands at the end of the first great period of English miniature painting. Its strength had lain in the breadth of patronage available as well as in the talent of the artists. There were already in the 17th century collectors of miniatures for their artistic or antiquarian interest, and part of Charles I's cabinet is still in the royal collection at Windsor castle.

**Continental Miniatures, 17th and 18th Centuries.**—During the 17th century there was neither so plentiful an output of miniatures on the continent of Europe nor so continuous a tradition as in England. Patronage was confined more narrowly to the immediate circle of the court. In France the most striking feature was the introduction of the portrait miniature on enamel and its early perfection in the hands of Jean Petitot (*q.v.*). Petitot was born and died in Switzerland and worked for several years in England, but his fame rests on the many portraits of Louis XIV and his entourage which he produced in Paris with the help of his brother-in-law Jacques Bordier. In Denmark Jacob van der Doordt (d. 1629) painted some miniatures for Christian IV; Paul Prieur (d. 1682 or 1683) worked as an enamelist from 1663; and Louis Goullon (d. 1680) painted miniatures in the next decade. Alexander Cooper (*q.v.*), the scarcely less gifted elder brother of Samuel Cooper, worked in Holland and went subsequently to Stockholm, where he worked for Queen Christina. Pierre Signac was miniature painter to the Swedish court from 1646 till his death in 1684, and was succeeded by Elias Brenner (1647–1717).

Throughout the 17th century some miniatures were painted in oils on copper, particularly in the Netherlands and Italy. Though often of excellent quality, these oil miniatures do not rival in interest works carried out in the usual mediums of water colour and body colour; and since such works are rarely signed little is known about the artists who produced them.

About 1700 the whole future course of miniature painting was influenced by the introduction of ivory as the painting ground in place of the vellum or prepared card which had been universal before the development of enamels. The artist responsible for the new departure was Rosalba Carriera (*q.v.*), who is well known also as a pastelist in Venice; it was probably suggested to her by the ivory snuffboxes for which she made decorative paintings. The advantage of ivory is that it provides a luminous glowing surface for transparent colours and correspondingly heightens their effect. However, it was some time before the full possibilities of the new method were appreciated. Many of the earlier painters upon ivory, such as the English artist Bernard Lens (1682–1740), used opaque colour and so deprived themselves of one of ivory's chief advantages.

In the early 18th century the enamel miniature enjoyed the greatest popularity among English patrons. The Swedish-born Charles Boit (1662–1727) produced work in this medium in London for William III and Queen Anne, and the German-born Christian Friedrich Zincke (1684?–1767) painted most of the celebrities of the Augustan era in enamels of a remarkably even quality. Benjamin Arlaud, who worked in the first two decades of the 18th century, was one of the last miniaturists to paint on vellum in England; in France his brother Jacques Antoine Arlaud (1668–1746) pursued a similarly successful career. In that country Jean Baptiste Massé (1687–1767) was one of the first to paint miniatures on ivory and a leader of the French revival of the art.

The second half of the 18th century witnessed a great expansion of miniature painting and the complete absorption in the various national schools of the technique of painting on ivory. The English still favoured a linear approach to drawing and modeling, thus preserving a continuity with the methods used as far back as Holbein and Hilliard and giving full scope for the transparency of the water-colour pigment and the translucence of the ivory. The continental miniaturists, on the other hand, preferred broad washes of opaque water colour with delicate gradations of tone, a method more akin to rococo oil painting. The chief master of the latter style is Peter Adolf Hall (1739–93), who was born in Sweden, settled in Paris in 1766 and was unquestionably the leading miniaturist there until the Revolution. His style is remarkable for its texture and subtlety of colouring, as well as for the geniality it displays; it is seen at its most characteristic in "The Painter's Family" in the Wallace collection, London, and in his portrait of Augustin Pajou in the National museum, Stockholm. A fellow Swede, Niclas Lafrensen (1737–1807), is best known for his miniatures of *galant* scenes of a type made popular by Jacques Charlier (*c.* 1720–90). Jean Baptiste Weyler (1747–91), Jean Laurent Mosnier (1743 or 1744–1808), Marie Gabrielle Capet (1761–1818), Louis Marie Sicard (1746–1825), Antoine Vestier (1740–1824) and François Dumont (*q.v.*) are among the many gifted miniaturists who laid the foundations of their success in France before the collapse of the monarchy. The leading Danish miniaturist was Cornelius Hoyer (1741–1804), who worked also in France, Germany, Russia and Sweden. Augustin Ritt (1765–99) studied in Antwerp and Paris before achieving renown as court miniaturist in his birthplace, St. Petersburg. Heinrich Friedrich Füger (1751–1818), miniaturist to the imperial house in Vienna, is exceptional in that he reveals an English influence in his style, which is of extraordinary accomplishment; he has been called "the Austrian Cosway."

**England and America, 18th Century.**—In the mid-18th century English miniature painting began to recover from a rather dull period. Nathaniel Hone (1718–84), Luke Sullivan (1705–71) and Gervase Spencer (d. 1763) painted works of small compass—often intended for wearing in bracelets—and of a simple charm. The first of the remarkable miniaturists who were fashionable from about 1770 was Jeremiah Meyer (1735–89), a foundation member of the Royal Academy, London. He modeled the features of his sitters with a succession of fine-hatched hairlines scarcely distinguishable at the ordinary viewing distance, and rendered their colourful costume with rococo abandon. His skill was equaled by Richard Cosway (*q.v.*), who drew with a soft, curving gray line. Cosway was the miniaturist of the fashionable world and echoes the beauty and elegance of the entourage of the prince regent. The closely wrought enamellike finish of John Smart (*q.v.*) has many admirers among modern collectors; this same period also saw the masculine portraiture of Ozias Humphry (*q.v.*) and the prolific output of George Engleheart (*q.v.*) and Richard Crosse (1742–1810). The taste for the miniature spread through wide sections of society, and scores of able miniaturists were available to meet this greatly increased demand. Among the better known were Samuel Cotes (1734–1818), Andrew Plimer (*q.v.*), Samuel Shelley (*c.* 1750–1808), William Wood (1769–1809) and Edward Miles (1752–1828). Ireland supported a school of miniaturists at this time, leading members of which were Charles Robertson (1760–1821), George Place (d. *c.* 1809) and John Comerford (*c.* 1770–1832). All these and many others have their individual styles and sense of the sitter's character; the remarkable uniformity of merit in the work even of secondary artists is a testimony to the wide proliferation of good taste in the period.

American miniature painting began in the second half of the 18th century and was strongly under English influence. John Singleton Copley (*q.v.*) is said to have copied English miniatures in the 1760s; Charles Willson Peale and Rembrandt Peale (*see* PEALE) were trained in London. The miniatures of Edward Greene Malbone (*q.v.*) are outstanding for their refined handling; his work ranks with that of Benjamin Trott (*c.* 1770–1843) and Charles Fraser (1782–1860) as the most notable produced by American miniaturists. Among other able miniaturists who worked in America are John Ramage (*c.* 1748–1802), Walter Robertson (*c.* 1750–1802), Robert Field (*c.* 1769–1819), Joseph Wood (*c.* 1778–1830), Sarah Goodridge (1778–1853), Henry Inman (*q.v.*) and Thomas Seir Cummings (1804–94).

**The 19th Century.**—The sharper lighting and more incisive rendering of features introduced by J. L. David into easel portraiture is reflected after the French Revolution in the miniatures of Jean Baptiste Jacques Augustin (1759–1832), a complete master of naturalism in this genre. A similar approach is seen in the works of the Italian miniaturist Ferdinand Quaglia (1780–1853), who settled in Paris, and in that of his countryman Domenico Bossi (1765–1853), who worked in most European centres. Jean Baptiste Isabey (*q.v.*) followed the same principles of naturalism in his earlier works, but his later portraits, the mirror of the first empire, are light, atmospheric and fluid in treatment. Paris remained a prolific centre for miniatures of the highest quality; of the many followers of Augustin and Isabey, Jean Urbain Guérin (1760–1836), Daniel Saint (1775–1847), Jean Baptiste Singry (1782–1824), André Leon Larue, called Mansion (1785–after 1834), and Mme. L. A. Z. de Mirbel (1796–1849) were much in vogue. In Austria, however, Moritz Michael Daffinger (1790–

1849) pursued a style wholly English in its affiliations.

A pronounced break in style is seen in English miniature painting at the start of the 19th century, caused by the resolve of Andrew Robertson (1777–1845) to give his miniatures the force of oil paintings. The taste for larger miniatures of rectangular shape asserted itself from then on. Though there were more miniaturists practising than ever before, fewer stand out. John Cox Dillman Engleheart (1784–1862), John Linnell (1792–1882) and Frederick Cruickshank (1800–68) are among the more individual, while Alfred Edward Chalon (1781–1860) and the Frenchman Simon Jacques Rochard (1788–1872) painted with a liveliness attuned to the court of George IV. A final achievement was added to the history of the art in England by the immense talents of Sir William Charles Ross (1794–1860), who infused his portraits of the notabilities of Queen Victoria's early years with his own serenity of temperament. The invention of photography was the greatest single factor in bringing the annals of miniature painting to a close: the art lingered both on the continent of Europe and in England and the United States into the second half of the 19th century and even into the 20th, but had effectually lost all continuity with the traditions of its former excellence.

**MINING, METAL.** Mining, broadly, is the industrial process of removing a mineral-bearing substance from the place of its natural occurrence in the earth's crust. When the term is used with specific reference to producing a metallic material, it is called metalliferous mining or, more simply, metal mining.

**History.**—Through the discovery and identification of tools and weapons and similar artifacts found in various archaeological sites over the world, it became evident that mining has been practised since before the beginning of written history. (*See* METALLURGY.)

Perhaps the first great scholarly and practicable treatise of mining was *De Re Metallica*, compiled by Georgius Agricola (Georg Bauer) and published in 1556. This classic journal, the writing of which took over 25 years, was translated from the Latin in 1912 by Herbert C. Hoover and his wife. The descriptions in *De Re Metallica* are remarkable for their clarity and detail; the text is also profusely illustrated and serves as an excellent source of knowledge of early mining practices. Many of the procedures described are similar to those of the 20th century. In addition to their translation and treatment of Agricola's text, the Hoovers assembled notes about even earlier written works on mining. For example, as early as the 4th century B.C., Aristotle and some of his students, such as Theophrastus, had written of mining matters; Pliny likewise contributed noteworthy writings. Other authors, including Avicenna (an Arabian physician), Albertus Magnus and Roger Bacon, compiled treatises on mining. For the most part, however, few records of importance were developed prior to 1500. Preceding *De Re Metallica* there were three works of major consequence issued in the 16th century about mining technology: *Nutzlich Bergbuchlin*, probably by Calbus of Freiberg, according to the Hoovers; the *Probierbuchlein*, a collection of essays by several authors; and an Italian treatise, the *De La Pirotechnia* by Vannoccio Biringuccio.

After Agricola, the printing of dissertations on mining waned until the first part of the 19th century, the *Mining Journal* starting in London in 1835. Technical articles then began to be published in many journals and several formal treatises were issued. Mining associations and institutions came into being in Europe in the mid-19th century and the American Institute of Mining and Metallurgical Engineers (A.I.M.E.) was founded in 1871. (In 1956 it was renamed the American Institute of Mining, Metallurgical and Petroleum Engineers).

Some mines, such as the Almadén mercury mines of Spain, the tin mines of Cornwall, Eng., and the zinc deposits of Silesia (Poland), have been worked for many centuries in the old world, but not until colonization of the western hemisphere started about 1500 did mining of consequence begin in North America. It is true that the Inca and the Aztec peoples of South America and Mexico had accumulated wealth of gold and silver but industrialized mining does not appear to have been an outstanding feature of these agrarian cultures. Although the North American Indians used some metallic substances for weapons, paints and utensils, they crudely fabricated them from minerals which they exploited only by ill-directed surface scavenging. Neither the Indians nor the Eskimos had even small mines, and they give evidence of having had little, if any, use for gold, silver and other precious metals.

The first recorded copper mining in the western hemisphere was in Cuba in 1524 and it was followed early in the 17th century by activity in Massachusetts and elsewhere along the eastern seaboard of North America. A little later, copper mining was started in Vermont and, as early as 1718, De la Motte Cadillac, a French mineral expert, and Philip Renault located and began to work the famous Mine la Motte lead deposits of southeast Missouri. It was not until the discovery of the tremendous iron and copper deposits in Minnesota and Michigan and the finding of zinc deposits in Missouri, Kansas and Oklahoma, together with those of gold and silver in California, Nevada and elsewhere, that the development of modern metal mining in North America began.

The growing populace of the United States, contemporaneous development of transcontinental railroads and, of course, the discovery of great mineral deposits contributed to a pronounced expansion of mining in the mid-19th century. Mining enterprises were spurred especially by the discovery of gold at Sutter's mill in California and later by the famous developments of Grass valley and the Feather river; by those of the Comstock lode and Tonopah in Nevada; Cripple Creek, Leadville and Silverton, Colorado; Tombstone, Jerome, Bisbee and Morenci, Arizona; Virginia City, Helena and Butte, Montana; Bingham, Park City, Ophir and Eureka in Utah; Orofino, Bay Horse and the Coeur d'Alene of Idaho; the Homestake of the Black hills of South Dakota; the gold rush to the Yukon in Alaska; and many other fabulously productive mining camps.

The search for mines was particularly intense after the Civil War and much of the speed of the development of the western U.S. is attributable to it. The great wealth that accrued also served as an incentive to people of other lands, and great mines were discovered elsewhere in the world. Just as the Cornishmen of the tin-copper mines of England, for example, brought their skills to assist in the building of the great mines of the U.S., American craftsmanship and ingenuity joined in the building of flourishing mining enterprises throughout the world. From Canada, Mexico, Venezuela, Brazil, Peru, Chile, Bolivia, South Africa, Rhodesia, Australia, Burma, India and other countries, there has been a steadily growing production of an expanding range of metals. By the mid-20th century, the trend was to the increasing production of such comparatively uncommon metals as cobalt, titanium, nickel and niobium (columbium), and a great mining rush to search out and develop deposits of uranium and related radioactive minerals swept much of the world.

**The Broad Scope of Metal Mining.**—The tendency in mining has been toward the increased use and improvement of mining machinery so that modern mines are characterized by tremendous capacities. This has contributed to: (1) better working conditions; (2) the exploitation of lower-grade metal-bearing substances; and (3) the building of mines of great dimension and further promise.

The mining of any metalliferous deposit is basically an enterprise conducted for economic gain. The work may be done as a surface operation or it may be done by an underground method. The mode of occurrence of the sought-for metallic substance governs to a large degree the type of mining that is practised. Each mineral deposit has its unique characteristics and may require a special method of mining for maximum efficiency. Some mineral deposits are very rich in metal content while others are

lean (low grade). Some are large, irregularly shaped masses of hard rock; others have more or less flat-lying, tabular forms such as those of many rock beds or strata. Some ore bodies are tabular in shape but are inclined or tilted. These are called veins or lodes. Deposits in which the metal is associated with loose or semiconsolidated sand and gravel masses are known as placer gravels or, simply, as placers. The added problem of depth also affects the mining method. If the rock containing the metallic substance is at a shallow site and is massive and widespread, it may be economically excavated by a pit or quarrylike opening on the surface. If the metal-bearing mass is tabular, as a bed or vein, and goes to a great distance beneath the surface, then it will entail the adaptation of some method of underground mining.

The mining industry is not a stagnant one. New uses are constantly found for metals. More efficient operating practices, lower costs per ton and better working conditions for employees always are sought. There has been a prevailing trend to supplant handwork by machinery, thus lightening the worker's physical burden. Because of the achievements after 1900, and especially after about 1925, in the development of large mining machines, metalliferous underground mining by the mid-20th century was pursued at remarkable depths and through very wide reaches of the earth's crust. At Butte, Mont., the underground openings reach to depths of about a mile beneath the surface and a labyrinth of over 3,500 mi. of passageways has been made under an area of the city extending about 2 mi. in an east-west direction and approximately 1 mi. north and south.

Many underground mines go to more than 5,000 ft. in depth. Some noteworthy operations are conducted on the famous gold-bearing Witwatersrand of South Africa where some mine workings have reached depths exceeding 11,000 ft. Another example of the magnitude of some underground mines is at the St. Joseph Lead company in southeast Missouri. There, excavations are so extensive that they are served by two completely equipped underground machine shops that are 5.51 and 3.67 ac. in dimension. These shops are about 6 mi. apart and are connected by mine passageways so that very flexible service is available. All types of the mining equipment used in the mines are repaired in these underground shops and some new devices of major size actually are built in them. Many other illustrations of the scope of underground mining ventures might be given.

In several near-surface occurrences of iron- and copper-bearing substances, tremendous surface excavations have been made. These enterprises are outstandingly successful, particularly at the iron mines of Minnesota and at many copper deposits in the Cordilleran mountain systems of North and South America. As one illustration, the great opencut mine at Bingham, Utah, of the Utah Copper division of the Kennecott Copper corporation can be cited. It is reported that over 180,000 tons of barren rock and 90,000 tons of ore (rock which is rich enough in metal content to be profitably mined) are excavated each 24-hour period. The opencut which has been developed is about 2 mi. across from rim to rim and deep enough to accommodate two upright Empire State buildings, one on top of the other. It resembles a great stadium where all of the people of New York city could be seated. Approximately 4 tons of explosives are used to break each 80,000 tons of the rock material. The rock is loaded into 100-ton railroad cars by electric shovels that scoop up 12 to 15 tons at each "bite."

Because modern mining operations involve so many types of machines and because they are frequently carried on in a subsurface environment where the responsibilities of the individual worker often are of abnormal scope, safety becomes of prime importance.

## THE MINING CYCLE

Most mining ventures entail an operating cycle which, in its usual sequence, is comprised basically of: (1) rock breaking (drilling and blasting); (2) mucking (loading); and (3) transporting (hauling and hoisting). Because of the wide variation of earth materials encountered in mining and because some are surface operations and others underground, the mining cycle is very flexible in its application. Some soft, earthy materials will not require drilling and blasting but, if the work is underground, they will require the installation of roof and wall supports. Much underground mining is carried on in stronger rocks, and the placing of roof props or roof bolts often will not be necessary. Roof bolts are devices to stabilize ground by fixing heavy nuts to the free ends of steel rods which have been hammered into drill holes that have penetrated sound rock deep enough to reach undisturbed material in depth. A semblance of a form of truss support thus is provided.

In addition to the basic work cycle of mining, other activities usually must be performed. These generally include the disposing of spoil rock (unprofitable, barren rock sometimes called waste), shaft sinking, distribution of power supply, ventilating, lighting, draining, surveying, making of geologic investigations and the installing and maintaining of mine plants.

**Rock Breaking.**—As most mining operations are pursued in rock materials that must be forcibly broken from the solid medium, they entail the use of explosives confined in holes placed in the rock mass. Rock breaking consists basically of drilling of blast holes, emplacing of explosives in the holes, and blasting or detonating. Before the perfection of explosives for mining, rock was broken from the solid with picks, hammers and wedges and, even earlier, by a method which used heat. A fire was built against the rock and when it became sufficiently heated, water was dashed onto it. Because of the sudden contraction, spalling and fracturing would ensue.

General drilling methods are: fire setting as described above; drilling by hand tools; and drilling by machine tools, usually of a percussion type and operated by compressed air. Drilling by hand tools is done by driving a sharpened steel rod like a chisel or pointed wedge into the solid rock which is to be broken. The rod is caused to penetrate by being struck with a heavy, hand-held hammer. The hammer may be used either in one hand and is called single jacking, or it may be swung by both hands and is then called double jacking. In machine drilling, the unit is made up of three basic components, the machine, the rod and the bit. Most drilling machines employed for blast hole drilling are of the hammer-drill type. They are classified as hand-held hammers (jackhammers, sinkers, etc.), drifters (light or heavy) and stopers, and are of many sizes, varying in weight and rotative power (*see* DRILLING MACHINERY).

The drill holes generally are drilled in patterns or systems, the number and depth of holes being largely governed by the character and size of the rock mass to be broken and by the mining method followed. The explosives employed in metal mining of hard rocks may be of special design and composition, but, for many operations, gelatin dynamites fabricated into sticks or cartridges are used. Cartridges are amenable to good emplacement in drill holes and have relatively high density and resistance to breakdown under moist conditions. In addition, they produce a minimum of toxic fumes when detonated. Other explosives include black powder, liquid oxygen, carbon dioxide and ammonium nitrate-fuel oil (AN-FO). Compressed air is used in some operations. (*See* also BLASTING.)

**Mucking.**—Mucking (loading) and transporting, though of distinct character, are difficult to divorce in a discussion because of their close sequential relationship and interdependency. The method of mucking is reflected in the choice and design of the haulage system. In fact, if maximum speed and efficiency are to be realized, the capacity of the haulage system must be correlated to the rate of loading.

Loading in many underground operations is from chutes where the ore has been dropped into binlike excavations called raises (*see* later discussion of underground mining [stoping] methods). In other cases, the muck is loaded by shoveling or some similar means. Prior to the introduction of mechanical loaders for underground use, mucking often was the bottleneck of efficient progress in mining operations. Hand loading is slow, tedious and laborious whereas mechanical loading appreciably reduces both the time of loading and the number of men required. (*See* SHAFT SINKING.) The flexibility of mechanical loading in large scale surface min-

ing operations demonstrates how mechanization can reduce the unit cost of a mining venture.

Loading procedures can be classified as follows: (1) Loading from chutes or bins. (2) Hand loading (shoveling), almost obsolete, especially in larger mining operations. (3) Scraper loading (sometimes called slusher loading), either surface or underground mining, may be driven by compressed air or by electricity. (4) Overshot loaders in which the digging element crowds, lifts and discharges directly into a car or truck. The action is similar to the way a hand shoveler would throw a shovelful over his shoulder, the cycle being controlled by the operator and the machine moving by means of flanged wheels on rails or on caterpillar treads. (5) Conveyor-type shovel loaders, machines which dig on the forward motion and deliver the load on the backward motion to an integrated conveyor belt that discharges into the hauling device. (6) Continuous-type loaders, which have gathering arms or rakes that move the muck onto a shaker pan or conveyor belt that in turn moves it into a car or truck. (7) Stationary shovels or dippers, machines which crowd and load from a stationary position, are mounted on railroad wheels or continuous tread and are powered by steam, electricity or diesel engines. They are commonly used in surface mining and often are of very large capacity.

Before leaving the discussion of mucking, a special mining procedure known as dredging should be described. It is a method of surface mining formerly of appreciable economic consequence and, though somewhat restricted in its industrial application, is the means whereby major quantities of gold, tin, platinum and other heavy mineral materials often are obtained. Where the sought-for metals occur in loose or semiconsolidated sand and gravel deposits and where sufficient water is available, dredging frequently is economically feasible. A dredge may be either a chain-bucket or dragline type. The former is a boat-supported machine with an endless chain of scoop buckets which dig down and forward through a pond of water and load the metal-bearing gravel onto concentrating (separating) tables on the dredge deck. Such machines were commonly used on tin mining operations in Malaya. After the metal values have been recovered, the gravel is dumped out the rear of the dredge by means of a conveyor belt, called a stacker. Some of the larger dredges can reach gravels at depths of over 100 ft. and the buckets can be constructed to scoop 15 cu.ft. or more during each pass. (*See* also GOLD.) The common dragline dredge is a conventional dragline loading machine mounted on crawler tracks and is operated to pick up loads of gravel in a scraper bucket by an intermittent scooping process. Each scraper-load is dumped into a bin or hopper for subsequent treatment on concentrating tables. The dragline unit is used on land and thus it does not require a large supply of water as does the typical bucket dredge, described above.

**Transporting.**—Hauling of rock is not a critical problem if the loading is done by hand shoveling, since almost any type of conveyance will move the muck as rapidly as it is supplied; *e.g.*, wheelbarrows, sleds, carts, mine cars (sometimes pulled by animals), small locomotives (usually electric or compressed-air powered) or cable hoists. However, in larger underground mining operations and at most surface mines the haulage is primarily by electric locomotives pulling trains of cars, or by pneumatic-tired trucks. The trucks usually are diesel or gasoline powered. In some large operations, they can cost $60,000 and transport as much as 40 tons to the unit load.

In the operation of most underground mines, it is necessary to move ore, men and supplies through a shaft from the surface. This is accomplished by a process known as hoisting, which employs elevatorlike devices called cages and skips that move on signal or at the will of the hoistman. A well-designed hoisting plant must not only be capable of efficiently moving ore from the mine, but it also must accommodate the handling of all machinery, drills, drill carriages, rails and ties, ventilation equipment, timbers, explosives and all other items of supply. Hoisting arrangements must be safe for moving personnel, strong, of adequate capacity, smooth working and fast. (*See* ELEVATOR, *Mine Hoists.*)

**Ventilating.**—Successful mining requires a working environment that is as equitable as possible. As underground mining steadily grows deeper and of wider lateral extent, it requires more extensive and complex ventilation practices. Deeper mining and the increasing use of mechanized equipment steadily induce complicating conditions. The purpose of ventilation in subsurface mining is to provide an atmospheric environment that is safe and comfortable. To do this, it is necessary to remove or dilute undesirable gases, dusts and smoke, to introduce fresh air into the system and to condition the atmosphere for proper temperature and humidity.

One of the first problems in designing a ventilation system is to determine how much air is required to maintain a safe, healthful atmosphere in the mine. In general, 100 to 200 cu.ft. of fresh air is needed each minute for each man working underground. Peculiar local situations such as the extent of the mine, the type and amount of explosives used, the frequency of blasting, geologic phenomena, humidity and temperature affect the amount of ventilation required. Air movement occurs by a differential pressure sufficiently great to set a given mass of air in motion and to overcome friction and shock losses caused by protuberances and abrupt bends of the line of travel. Devices capable of producing air movements are: airscrews, such as propellers; centrifugal fans; rotary, positive blowers; injectors, such as Venturi blowers; compressed air blowers; ventilating furnaces, such as free, hot air systems; water sprays; deflectors and sails.

To suitably condition the atmosphere at great depths below the surface, it is commonly necessary to establish cooling systems as well as direct ventilating devices. The cooling units may be mechanical refrigerating machines or they may be designed to work as heat exchangers of the cooling-tower or spray-tower types.

## CLASSIFICATION OF METAL MINING METHODS

As has been discussed, the choice of a mining method to exploit any metal-bearing deposit depends on several related factors, of which the chief ones are: size and shape of ore-bearing mass; degree of richness of the ore; depth of occurrence; geographic location; and labour supply. A classification of the general methods of metal mining, as modified after the arrangement used by the American Institute of Mining, Metallurgical and Petroleum Engineers, follows:

- Opencut Mining (with or without stripping)
  - Benching
  - Glory-hole Mining
  - Placer Mining
    - Sluicing and hydraulicking
    - Dredging
- Underground Mining
  - Breast Stoping (tabular, flat-lying deposits or beds)
    - Continuous horizon
    - Drift mining
    - Casual pillars
    - Rooms and pillars
  - Underhand Stoping (veins and large masses)
    - Glory-holes with pillars
    - Open stoping
      - Stulls
      - Square sets
  - Overhand Stoping (steeply inclined veins or masses)
    - Open stopes
      - Pillars
      - Stulls
      - Square sets
    - Filled stopes
      - Horizontal cut and fill (flat back)
      - Inclined cut and fill (rill)
      - Square sets
      - Resuing or stripping
    - Shrinkage stopes
    - Sublevel stopes
  - Top Slicing (wide veins or masses)
    - Continuous horizon
    - Panel slicing
    - Block slicing
    - Inclined slicing
  - Caving (large masses)
    - Sublevel caving
    - Block caving
      - Undercut from main level
      - Undercut from sublevel
      - Block caving into chutes
      - Block caving with branch raises

**Opencut Mining.**—Opencut, open-pit or opencast, mining practices comprise the working of metalliferous deposits which either outcrop at the surface of the ground or are covered by a shallow overburden or capping. There is an economic limit to the maximum thickness of overburden that can be removed and, when such a limit is exceeded, some method of underground mining must be adopted. The depth of capping may vary from a few feet up to 300 ft.

*Benching.*—Power-driven shovels working on benches load the ore into railroad cars or diesel-powered trucks (*see* fig. 1). The muck is loosened by blasting, and care is taken that the pieces are small enough to be handled readily by the shovels. The height of bank is determined by the thickness of the deposit, the size of the shovels, the physical character of the ore and climatic conditions. The higher the bank, the more material the shovel can handle from one position, but the greater is the danger of a slide burying the shovel and of falling rock injuring the men. The material may stand at a high angle when dry, but slides may occur in wet weather. Thick deposits are worked in several benches; the slope of the banks which extend from bench to bench varies at different mines, but for preliminary investigations may be taken as 45° from the horizontal. This gives a general slope (including both benches and banks) of from 35° to 40° for the entire side of the cut.

The shape of the ore body has an important bearing on the feasibility of opencut mining. Because of the slope which the sides of the cut must take, a narrow ore deposit cannot be mined as economically by this method as can a large flat-lying one. If the deposit is irregular or veinlike in outline, it may be difficult to prevent diluting the ore with waste and even under favourable conditions it is seldom possible to mine the entire body without resorting to underground mining for the lower part of it.

The electrically operated shovel fitted with caterpillar tread has largely superseded the steam shovel, especially in large scale work. The electric shovel eliminates the problems of water and fuel supply, a fact which makes it particularly advantageous in cold weather. Power-shovel work, because of the high cost of equipment, must be on a large scale, and consequently can be economically applied only to big ore deposits.

*Glory-hole Mining.*—In this case a vertical connection, called a raise, is driven to the surface from an underground haulage way. The top of this raise is broken out to form a funnel-shaped opening, which is widened and deepened by blasting around the inside.

FIG. 1.—OPENCUT OR OPEN-PIT MINING. POWER SHOVEL IS LOADING COPPER ORE INTO A TRUCK

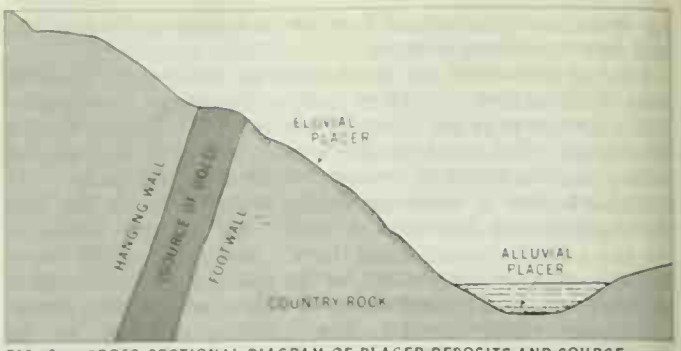

FIG. 2.—CROSS-SECTIONAL DIAGRAM OF PLACER DEPOSITS AND SOURCE

The broken ore slides down the funnel into the raise which serves as a chute, the ore being drawn off through gates into cars on the haulage level. This is a cheap method of mining, but it is dangerous especially if pieces of the wall tend to break off and the excavation is large.

A series of holes may be mined and widened until they intersect. The intervening ridges then are worked out.

*Placer Mining.*—This is a surface mining method applied to deposits of minerals accumulated into workable quantities of economic importance through the natural geologic processes of weathering, erosion and deposition. An alluvial placer occurrence is one formed by the mechanical action of moving water, whether of streams or lakes or along a seacoast. Eluvial is a term applied to placers formed mainly by weathering and thus it is found close to the parent rock (*see* fig. 2). Erosion of the parent rock has set free the heavy, metallic components and these have worked down the slope because of the combined action of gravity and washing by rains. Once a flowing stream is reached, the metal may be carried a long distance before it is deposited. A placer deposit may be formed by concentrations of gold or tin or by a number of other minerals, but mining for gold is generally the most common. A few workable placers have been formed also by the action of wind, which carried away the lighter minerals leaving a residual, heavier mineral deposit which is of economic importance.

The size of placer gold varies from nuggets of 2,000 oz. troy or more to very fine flakes. Small pockets of auriferous or gold-bearing gravel may be worked by hand by using a pan or a rocker to separate the gold from the gravel mass. A rocker is a small wooden trough or box mounted on two transverse rockers so the device can be given a shaking or rocking motion which tends to cause the heavy metals to sink out or go to the bottom of the mass.

By diligent work an experienced panner can handle about 1 cu.yd. of gravel in ten hours. Two men with a rocker can work from 3 to 5 cu.yd. of gravel in approximately ten hours under average conditions.

Sluicing and hydraulicking broadly are mining methods in which a slightly sloping wooden trough (box sluice) or a ditch cut in hard gravel or rock (ground sluice) is used as a channel along which gold-bearing gravel is carried by a stream of water. Riffles, in the form of cobblestones, wooden blocks, wooden poles or steel rails, are placed transversely along the bottom of the sluice to cause the water to eddy into small retarding basins so that the current is reduced and the gold may settle and thus be trapped. Sluices vary from 1 to 6 ft. in width and from 1 to 4 ft. in depth, their cross section being proportional to the volume of material passing through them. Their length should be sufficient to allow the gravel to disintegrate and the gold to settle. This usually takes place in the first 100 to 300 ft. The slope or grade of sluices is commonly specified as the number of inches that are dropped in a length of 12 ft.

Sluicing is the term applied to working placers where the gravel is carried to the head of the sluice by shoveling, in wheelbarrows, in small cars, by scrapers or by dragline excavators. Large placer deposits are worked by hydraulicking, gravel being loosened from place and washed into the sluice by powerful jets of water from nozzles called hydraulic giants or monitors. To be effective, the

head of water on the giant should not be less than 200 ft., which is equivalent to a pressure of 86.5 lb. per square inch. Water for the hydraulic giant is measured in terms of the miner's inch, or a flow of 1.5 cu.ft. per minute. As a rough guide, under average conditions a miner's inch will move from 3 to 6 cu.yd. of gravel per 24 hours.

Hydraulicking is employed in underground mining operations in Russia, China and Poland to burst off coal from the solid face. Gilsonite, a solid hydrocarbon, is mined by this method in Utah.

**Underground Mining.**—There are numerous types of underground mining or stoping (*see* classification outline above). Their general characteristics are presented below. Stoping is used as a general term to indicate the process whereby ore-bearing materials are produced commercially during an underground mining operation. The underground excavation in which the miners perform their work is called a stope.

*Breast Stoping.*—Breast stoping is a method of mining that may be applied to thin ore deposits that either are flat-lying or inclined (dipping) at a small angle to the horizontal. The thickness of deposits worked by this method usually is not over 12 ft., although in modified form this system may be applied to beds up to 70 ft. In thin deposits the entire thickness of ore is mined at one time, thus advancing the work in a vertical face or breast. In thicker deposits the ore is mined in a series of crude or rough benches. Continuous horizon implies a long working face which is attacked simultaneously at a number of points.

Drift mining, as it is used with reference to the exploitation of placer deposits, is a variety of breast stoping. The paystreak or zone of major concentration of sought-for values is reached through a horizontal, tunnellike opening called a drift or sometimes under special cases an adit (*q.v.*), or through a shallow, vertical shaft. Small cars commonly are used for transporting the gravel which is removed in some system of regular cuts or slices across the paystreak.

Timber posts and headboards usually serve to support the roof but, if the gravel is so loose as to "run," tight timbering or a method of forepoling (which is the lengthwise driving ahead of sharpened supporting timbers before the ground is excavated) must be used.

Gravel that is frozen, such as that which is quite often encountered in Alaska and other places of the northern latitudes, must be thawed before it can be mined. Steam, hot water or cold water have been used successfully for thawing, being forced into the frozen gravel through pointed pipes that are applied somewhat as hypodermic needles.

Breast stoping in the Missouri lead and zinc region is done by leaving casual pillars of ore deposit to support the roof. These pillars, left at irregular intervals as the name signifies, range from 10 to 40 ft. in diameter. From 10% to 15% of the ore generally is left in the pillars, depending upon the hard or soft nature of the floor, the strength of the roof and total weight supported. The recovery of ore from the pillars is low, it being usually more economical to leave some of the ore than to use artificial means of roof support.

Small power shovels or scrapers commonly are used in the stopes for gathering and loading the broken ore.

The room and pillar method of stoping is that of cutting the ore deposit into regular lines of square or rectangular pillars, which later are removed as much as possible. It is not uncommon to leave, temporarily at least, as much as 50% of the ore in the pillars.

*Underhand Stoping.*—As the name implies this is a method of working a vertical or steeply inclined ore body from the top down. Holes for blasting are drilled downward and the rock which is broken must be shoveled and hoisted as in digging a pit, or in more extensive operations it may be moved downward to a previously formed excavation lying below. In the mining process, it is customary to concentrate the handling of ore and waste and the distribution of supplies on certain horizons called levels, which are commonly spaced 100 ft. apart vertically, though this distance may be lessened or increased in some mines. On any level the passageways driven lengthwise of the vein are called drifts and those driven across the vein from wall to wall are called crosscuts. If the vein is inclined, the upper or overhanging ground is the hanging wall, and the lower, underfoot zone is the footwall (*see* fig. 2). Two levels may be interconnected by vertical or inclined openings, called raises if driven upward from a level, and known as winzes if excavated downward from a level. Thus, a connecting opening may be a raise or a winze depending upon which level it has been driven from. Raises and winzes are ordinarily timbered to afford at least two closed compartments, one to be used as a chute for ore or waste and the other fitted with a ladder to serve as a manway. The term back is applied to both the roof, arch or top surface of an underground mine working and to the entire body of ore lying between a level and the next one above.

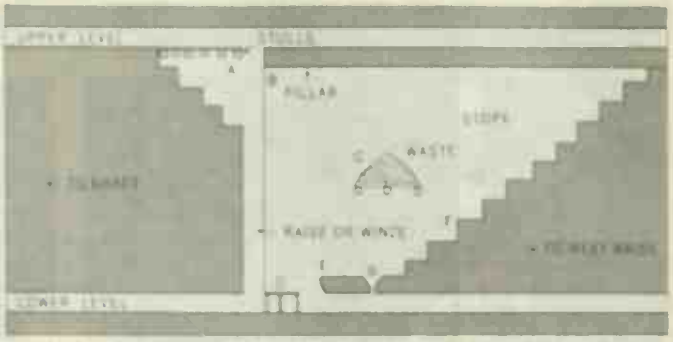

FIG. 3.—VERTICAL LONGITUDINAL SECTION OF UNDERHAND STOPE

An underhand stope (*see* fig. 3) is started by working outward from the top of a winze in a series of horizontal slices, which operation leaves the underlying unmined ore in a rough, steplike form. To protect a lower level during the stoping process and to provide a means of loading cars, the lower level is either timbered, as shown at D, or a pillar of ore, E, is left, through which chutes, G, are cut at intervals of 25 to 50 ft. The face of the ore forms a rough slope or series of steps as indicated at F. The angle of repose of broken ore in the stope is from 35° to 45°, the steeper angle being for hard ores. If possible, the slope should be maintained of such steepness that the ore which is mined will slide downward.

If the ore is rich, timbers called stulls or props are covered with planks, called lagging, to form the bottom of the upper drift, as at A, but if the ore is lean (low grade), it is usually more economical to leave a pillar of ore as at B. Should the level be the lowest level in the mine, the ore must be hoisted to the top of the winze, but as the cost is comparatively high, this procedure is used only for recovering small bodies of ore below a level. When underhand stoping is applied to large ore bodies it generally takes the form of underground glory holes, sometimes called mill holes, one series of holes being separated from another group by an intervening pillar of ore. In these cases, as in the working of a narrow vein, the men are in danger of rock falling from the back or walls of the stope, hence the desirability of having a firm back and strong walls.

*Overhand Stoping.*—In this system of mining where open stopes are used, they are advanced upward, the ore being removed in horizontal, vertical or inclined slices. The stopes are started from the bottom of a raise, either from the top of a protecting pillar of ore, as at P, fig. 4 (B), or directly off the level, as at S, in which case the level is protected by stulls or square or drift sets (framed-timber units) which are covered with lagging. As the stoping proceeds upward the miners must have some support on which to work. For veins having an inclination or dip of 40° or less, the men can work directly by standing on the footwall, but in steeper ore bodies, the stulls or other timbers are covered with lagging to afford temporary working platforms.

The practice of filled stopes is used if the ore is likely to fall very soon after it is undercut and if the walls are weak. This is done because a stronger support than can be given by timbering alone is required and thus the filling of the stope with rock material of uneconomic value is resorted to. This nonvaluable rock is secured

FIG. 4.—LONGITUDINAL SECTION VIEWS OF OVERHAND STOPES

by sorting the ore, by driving small drifts or inclined raises into the barren walls of the deposit or getting the rock from outside the mine. The horizontal-cut-and-fill or flat-back system of overhand mining is shown in fig. 4(C). At H the cut is being made horizontally to the right, the miners drilling holes from the top of the pile of broken ore at O. Chutes, C, are for drawing off the ore to the level below. These timbered chutes are built to keep the top just above the waste filling, W, which is brought in on the upper level and dropped down the waste chute in the raise to be distributed by cars or scrapers through the stope. As the mining progresses away from the main raise, additional waste raises, B, are driven at intervals to save hauling distance. Before a slice of ore is shot down, the waste filling is leveled and covered with planks. The planks are removed when waste is to be dumped. After the slice H has been carried beyond the first waste raise, another slice may be started from the main raise. In this way several sets of miners may be working simultaneously in a stope. The ore chutes may be built of large pieces of waste arranged in circular form and some support to the back, that is, the body of ore overhead, may be afforded by cribs built on the waste or on the ore as at A, fig. 4(C), but no heavy weight can be supported in this way.

The method of mining called inclined-cut-and-fill stoping, known also as rill stoping, is a type of overhand stoping in which inclined slices are taken, as is shown at R, fig. 4(A). The method works well where the ore is hard and the walls are firm and regular. The slices or cuts are made either from the top down or the bottom up, the miners standing on the broken ore. After a slice has been shot down and the ore has drawn off at the level below, waste is brought down the raise from the level above. The waste runs in under the influence of gravity and takes its own angle of repose. A layer of planks then is laid on the waste, another slice of ore is shot down and drawn off, and the planks are removed for the next layer of waste filling. Both ore and waste require a minimum of handling. At T, fig. 4(A), stulls and posts are used as support. Here, the broken ore is shown lying on the plank-covered waste, W. As the stope increases in height, the lower point, or toe, moves away from the raise. The danger of falls of rocks from the back limits the length of the stopes, which in some cases may be only 50 to 60 ft. An ore chute is started from the level at the toe of the slope and is carried up, keeping pace with the waste filling. Sometimes no planks are used in the stope inasmuch as water is used to wet and thus to compact the surface of the waste before the ore is shot down. After the ore is drawn off, the fine material remaining is carefully scraped off the waste before additional filling is run in.

A flexible method of stoping is one wherein filled square sets are used for mining of especially heavy (insecure) ground. The term square sets refers to a particular type or system of timber supports in which each of the several component units is known as a set. That is, a complete set is composed of 12 pieces of timber, as shown in fig. 5, four each of posts P, caps C and girts G. As additional sets are added each timber becomes common to four adjacent sets. Round timbers also may be used in sets, but they require a slightly different framing or end design. Sets are held in place by short blocks placed at the corners and wedged tightly against the walls of the stope. By extending sets vertically and horizontally this skeleton framework of timber may be shaped to fit a stope of very irregular outline. By varying the number of sets opened laterally on the bottom or so-called sill floor of a stope, and by limiting the vertical number of sets left unfilled, this system can be made to suit the nature (degree of instability) of the ground being mined. If no great pressure is brought on the timbers, a sill floor 12 to 15 sets wide, or even more, may be opened. However, in the mining of ground that has a tendency to slough, the sill floor may be only two or three sets in width. This area of horizontal or lateral cut is carried up to the level above, and then another similar cut is started next to the filled sets, and the operations are repeated. Thus a large block of heavy ground may be safely mined in a series of small vertical slices. Chutes and manways are made by lining square sets tightly on the inside with vertically placed planks or lagging.

Resuing or stripping is applied to the mining of narrow veins or of veins in which rich ore lies in a streak of less width than the vein as a whole. The object of resuing is to mine the ore clean and free from waste, and thus save diluting the ore with waste and sending a larger tonnage of lower grade ore to the mill or smelter. This is done generally by first mining the lean or worthless portion of the vein; the high grade streak then is drilled and blasted to yield a separate, comparatively rich material.

Shrinkage stoping is a type of overhand stoping in which only enough ore is drawn progressively from the stope to afford working space so that the miners can stand on broken ore while drilling holes in the back. Broken ore occupies about 60% more volume than ore in place; consequently, about one-third of the ore must be drawn off, as it is broken, through chutes closely spaced, from 25 to 50 ft., along the bottom of the stope. Two-thirds of the ore is left in the stope. This method is best suited to veins or tabular masses of hard, uniform character, in which the walls are firm and regular and which are dipping (tilted) at not less than 50° from the horizontal. A disadvantage of this method lies in the long time the ore is left in

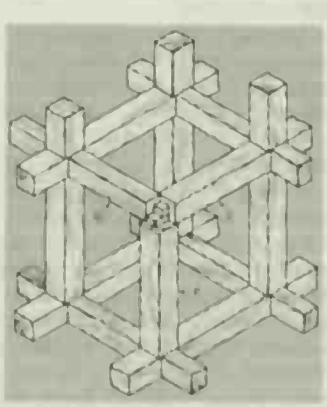

FIG. 5.—TIMBER SQUARE SET

stopes, two or three years in some cases, before it can be removed for milling or smelting.

Fig. 6 is a longitudinal diagram showing shrinkage stoping as applied to a large ore body. The lower level is protected by a pillar through which short raises, C, for chutes are put up at 25-ft. intervals. Raises are driven through the pillars at the end of the stope. Short cuts, driven through the pillars at small vertical intervals, connect with the working space in the stope, as shown at M. To prevent large pieces of ore from clogging the chutes, grizzlies (bar screens), G, are placed at the top of the chutes C. A pillar of ore, as indicated at P, may be left to protect the upper level. Later, the pillars are mined by another method.

The principles of sublevel stoping are illustrated in fig. 7. Main levels usually are from 100 to 150 ft. apart, and are connected by raises as needed. At vertical intervals of 20 to 25 ft., sublevels 7 to 8 ft. high are driven from the raise to the end of the stope. Each sublevel is commonly a single drift down the centre of the stope. By driving crosscuts at the end, sublevel No. 1 is for a short distance widened to the limits of the stope. Inclined holes are drilled around the chute raises C which are put up from the haulage level at intervals of 25 ft. or even less. These holes are blasted to give a funnel-shaped top to the chutes. The sublevels are taken back in benches by progressive stoping from each sublevel to the one above. For example, after stoping has begun in sublevel No. 1, sublevel No. 2 is taken back by first crosscutting to the full width of the stope, and then drilling down-holes in the floor to remove part of the lower pillar and "uppers" in the back to take out half of the upper pillar. Thus miners in No. 2 sublevel retreat toward the raise, drilling down-holes in slice B and up-holes

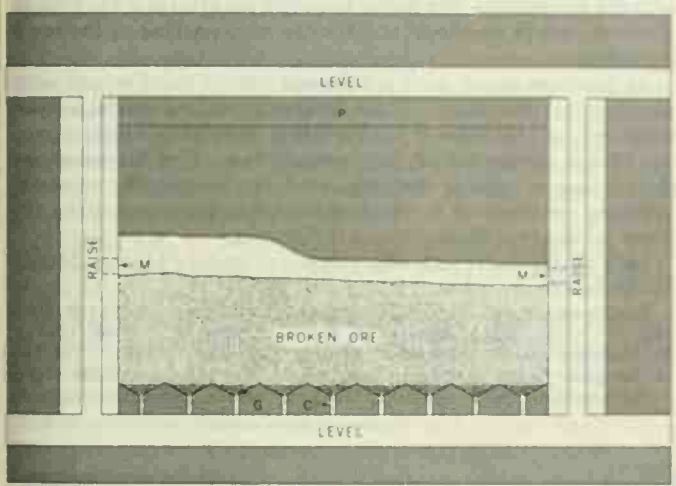

FIG. 6.—LONGITUDINAL SECTION, SHRINKAGE STOPING

in slice D. The same sequence is followed for sublevel No. 3, the broken ore falling toward and into the funnel-shaped chutes. In wide stopes, 40 to 100 ft. in width, two parallel haulage drifts may be driven. These are connected at intervals by crosscuts as at A. This method entails a high cost for development, but requires little timber and gives a large output from each stope because of the several working places.

*Top Slicing.*—Top slicing by the continuous horizon method is done in horizontal slices, 10 to 12 ft. thick, working downward from the top of the deposit. The first slice is taken just beneath the capping, which is supported by timbering. As the slice of ore is taken out, lagging is laid on the floor to cover tightly the ore below. The posts supporting the capping are then shot out and the capping caves onto the timber floor or mat. This mat is temporarily supported by the timbering that is installed as the second slice is taken. After the ore in the second slice has been removed, a timber floor again is laid and the posts are shot out. Thus, the timber mat, which serves to prevent the capping from mixing with the ore, receives additions as each slide is progressively stoped. From the haulage level a raise, containing a chute and manway, is put up to the top of the ore and a main drift is driven to the boundaries of the block. Cross drifts are turned off at right angles

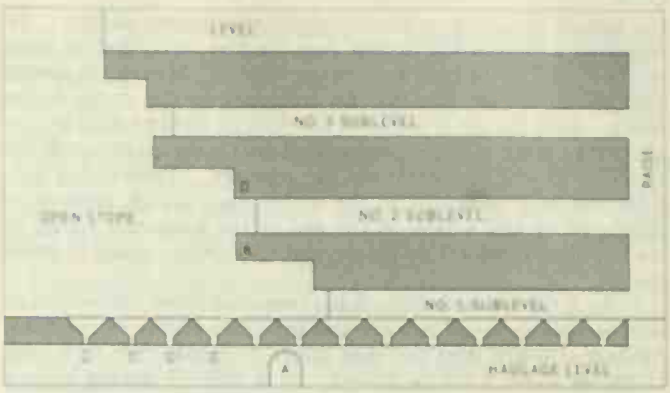

FIG. 7.—LONGITUDINAL SECTION, SUBLEVEL STOPING

to the main drift and are driven to the limits of the block. The ore is broken by breast stoping, and is shoveled into cars to be hauled to the chute. After a cross drift has been completed, the floor is covered with a layer of timber and the posts are shot out, using small charges of dynamite. The overlying capping or timber mat settles down onto the new floor. In variations of this mining practice a form of square-set timbering is used, and successive cuts may be two sets wide and two or three sets high.

By using a stoping method of either panel, block or inclined slicing, a large ore body is not worked in one continuous horizon, but rather in a series of blocks or panels. Inclined top slicing was devised to save shoveling the ore. The cuts (frequently called slices) are inclined upward from the chute at an angle of 33° with the horizontal, so the ore will roll or slide down to the chute. This method does not permit sorting of the ore in the stope and is more difficult to work than horizontal slicing. Top slicing is applicable to weak ore with poor walls. It is most suitable for deposits of large horizontal extent which have a capping that caves readily. It is a safe method and gives as much as 95% extraction of ore.

*Caving.*—Sublevel caving is suitable for the large-scale mining of ore that is moderately hard, and that has fairly regular limits and a capping which caves readily. Fig. 8 illustrates the principles of the practice although details vary at different mines. From the haulage level, raises (R) are put up at about 50 ft. intervals, and sublevels are driven from the raises at vertical intervals of from 15 to 18 ft., leaving a horizontal pillar of ore about 9 ft. thick between the sublevels. The development work on each sublevel consists of longitudinal drifts, marked No. 1 sublevel, No. 2 sublevel, etc., and cross drifts marked D. These are spaced about 50 ft. apart. Mining is started on the top sublevel, No. 4 in fig. 8, by driving a cross drift parallel to D across the block of ore at the end of the sublevel. The drift is timbered with three-piece sets of two slightly inclined posts and a cap and is lagged (slabbed over) overhead. A second drift is driven alongside the first one.

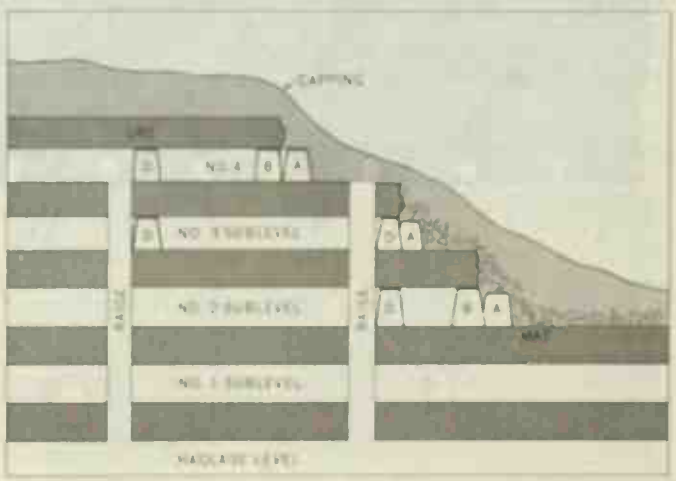

FIG. 8.—LONGITUDINAL SECTION, SUBLEVEL CAVING

the feet of the posts in the two drifts overlapping slightly. By removing a little of the lagging over the first drift, shallow holes can be drilled in the back and the ore blasted. Men in the second drift shovel the ore into cars for tramming to the chutes in the raises. After the ore is removed, the floor of the first drift is covered with a layer of timber, and a third drift is driven alongside the second drift and the operations are repeated. The capping subsides and, as it is caught on the timber mat, enough pressure is developed by this weight on the end of the horizontal pillars of ore to reduce considerably the amount of blasting needed to break the ore.

In fig. 8 the ore over drifts A has been shot down. Shovelers in drift B have removed this ore and have laid planks on the floor. As soon as a new drift has been driven alongside drift B, mining of the ore above B will be started. As in sublevel stoping, mining is done in a series of steps. From one-half to two-thirds of the ore is broken by the caving that ensues.

In the block caving method, a block of ore is undercut, and then subsides through the height of the undercut. This relatively minor movement of the ore is sufficient to break it into small pieces. Ore bodies should be large, and the ore must be firm enough to stand well during the work of undercutting and yet be brittle enough to break up well during the process of settling. The capping should cave readily. The broken ore is drawn off at the bottom of the block until capping appears. If undercut from the main level, the block is cut by intersecting drifts and cross drifts into a series of pillars, which are as small as safety permits. The pillars are drilled and blasted, and time is allowed for the ore to settle. The broken ore is mined by driving a series of closely timbered drifts into the shattered material. The ore runs in at the ends of the drifts and is shoveled into cars. When waste appears a few sets in the drift are blasted down and drawing is resumed at a new point, thus following a retreating system.

If a block is undercut from sublevel, the general features are similar to those just described. From the main haulage level, drifts are turned off at right angles at, say, 50 ft. intervals, and are driven to the limits of the block. A sublevel is driven above the main level, and the block is undercut by intersecting drifts and cross drifts on the sublevel. Chutes are put up to the sublevel from the haulage level. The pillars are blasted and the ore is worked into the chutes.

Block caving by using branch raises is a method followed at several large copper mines. It is illustrated in fig. 9a and 9b. From the haulage level, main inclined chutes (also called transfer raises), I, are driven to the grizzly level, where drifts, G, are used to connect a line of chutes. The tops of the chutes are covered with a grizzly made of rails to catch the large pieces of ore which would tend to choke the chutes. From the grizzly level, inclined chutes, K, are carried up and terminate in a square set, C, from which two or four inclined "finger" raises, F, are driven to the undercutting level at the bottom of the block. The tops of the finger raises are spaced 12.5 ft. apart each way, thus offering an ample number of points for drawing off the caved ore.

The ore is undercut by running a series of drifts, D, 25 ft. apart to the limits of the block. At one end of the block the ends of the drifts are widened. Holes then are drilled in the intervening ribs or pillars and in the back. Blasting these holes generally starts the caving. Shrinkage stopes, called boundary stopes, are made across the ends or sides of the block before the ore is undercut to separate it from the adjoining ground and thus to facilitate the caving. This method is suitable for ore that is soft or of medium hardness in which there is little or no waste. The capping should follow down freely and the ore should break into fragments small enough to run well into the chutes.

A thick body of ore may be worked in more than one lift. For a given amount of development work, the higher the lift taken the less is the cost per ton for the development work, as the cost is spread over all the ore in a block. However, other factors such as the horizontal extent of the ore and the economic life of the working also must be considered. Because the method is applied to low-grade copper ores bearing generally between 1% and 2% copper, special care must be taken to keep the diluting of the ore by waste to a minimum. The line of contact between the broken ore and the cappings (*see* fig. 9b) is usually between 40° and 70° with the horizontal. The flatter the angle the greater is the amount of broken ore in the stope, and trouble from packing of the ore is increased.

As has been noted, each ore deposit has its peculiar and often complex characteristics. These frequently induce special adaptations and combinations of the foregoing methods, or even a practice that is unique for efficient exploitation. For discussion and illustrations of mining methods used for nonmetallic minerals, including conventional mechanized mining, continuous mining and auger mining, *see* COAL AND COAL MINING.

**MINING ENGINEERING** is an amalgam of many branches of engineering. Long before the majority of the world's major engineering schools had been founded, mining schools had been established throughout Europe. Typical of such schools was Bergakademie Clausthal at Clausthal-Zellerfeld in the Harz mountains, founded in 1775.

In the late 19th and early 20th centuries the phenomenal increase in the demand for metals and minerals and the opening up of new areas providing opportunities for the discovery and exploitation of rich mineral deposits created a need for large numbers of competent engineers and many mining schools were established.

In these early days the isolated location of most mines forced the mining engineer to assume many duties. He was responsible for prospecting; construction of buildings, roads and structures; provision of compressed air, water and electricity; analysis of ores; and possibly even supervision of crushing, grinding and concentration of the ore, all in addition to the main task of actually getting the ore excavated. The profession of mining engineering was generally assumed to include some knowledge of these many overlapping fields.

With the tendency toward specialization typical of all fields, mining engineering has become confined to the problems of breaking ore and excavating it from underground mines and surface pits. *See* BLASTING; DRILLING MACHINERY; COAL AND COAL MINING; MINE PROSPECTING AND DEVELOPMENT; MINING, METAL; QUARRYING; SHAFT SINKING.

The discovery of ore deposits relies heavily on the theories and techniques noted under GEOLOGY and GEOPHYSICAL PROSPECTING. Analysis of ores makes use of many procedures described under ASSAYING; CHEMISTRY: *Analytical Chemistry* and SPECTROCHEMICAL ANALYSIS. The milling of ores has become a separate field described under ORE DRESSING. *See* also METALLURGY: *History* and *Ores and Ore Treatment*. (A. W. S.)

**MINISTER,** an official title both civil and ecclesiastical. *See* AMBASSADOR; CABINET; DIPLOMACY; MINISTRY, GOVERNMENT; MINISTRY, CHRISTIAN.

**MINISTERIALES** (from Latin *minister*, "servant"), a class of officials whose rise from servile status to nobility was a peculiar feature of German history in the middle ages. The *ministeriales* were originally unfree personal servants holding the higher positions (butler, chamberlain, steward, etc.) at the courts of ecclesiastical and secular princes. At first maintained in their lord's households, they were later granted fiefs, the tenure of which was by special virtue of their office. This raised their social position, which was further improved when they were entrusted with political, military and administrative tasks and powers. The extension of public administration from the 11th century onward caused this class of "civil servants" to grow steadily. There developed on the one hand a certain uniformity in the legal status of the *ministeriales* and on the other an increasing differentiation among them according to the posts that they held and according to the rank of their lords. Above all, the so-called *Reichsministerialen*, in the service of the German kings, played an important political role under the Salian and Hohenstaufen rulers: in Germany they strengthened the kings against the princes, and in Italy they were the leading military commanders and administrative officials (the *ministerialis* Markward of Annweiler, for instance, became regent of the kingdom of Sicily after the death of the emperor Henry VI).

From the 12th century, moreover, while impoverished free men often joined the ranks of the *ministeriales*, the *ministeriales* themselves married ladies of noble birth. They began also to hold ordinary fiefs beside those held by virtue of their office; and, as the latter too became hereditary in course of time, the distinctions based on form of tenure disappeared, so that the feudal law of the *ministeriales* became assimilated to the general feudal law of Germany. From the 14th century onward the *ministeriales* no longer showed any traces of their unfree origins, being accepted as of equal birth by the old nobility. Recognized as members of the estate of knights, they formed the core of the lesser nobility; and some families of *ministeriales* even rose to the rank of immediate princes of the empire, with territorial sovereignty (for instance the house of Reuss).

The *Reichsministerialen* lost their major importance with the end of the Hohenstaufen dynasty; in many cases they and their fiefs fell under the dominion of the princes of the empire. Under these princes, however, they came likewise to occupy the highest posts in army and in the administration.

**MINISTERS OF THE SICK** (CAMILLIANS; ORDO CLERICORUM REGULARIUM MINISTRANTIUM INFIRMIS; M.I.), a Roman Catholic order of clerks regular founded by St. Camillo (*q.v.*) de Lellis in 1582 (confirmed 1586) for hospital work. They numbered about 1,300 in the 1960s, fewer than half of whom were priests. *See* ORDERS AND CONGREGATIONS, RELIGIOUS.

**MINISTRY, CHRISTIAN,** those Christians believed to be called by God and set apart by ecclesiastical authority to minister in the church. This article deals first with the origins of the traditional ministry of bishop, priest and deacon, and second with the ministry in Protestant churches. For further information *see* HOLY ORDERS; ORDINATION; EPISCOPACY; CLERGY; BISHOP; PRIESTHOOD; DEACON; DEACONESS; ELDER; and the articles on the separate churches.

## THE TRADITIONAL MINISTRY

According to the belief of the majority of professed Christians, a belief that was largely unquestioned until the Reformation, the Christian ministry is threefold and consists of bishops, priests and deacons.

**Bishops.**—Evidence shows the existence of bishops in several centres of Christianity in the early 2nd century and in all centres by *c.* 200. The origins of this order are, however, obscure and any theory is unlikely to convince more than a minority of scholars. The facts that may be gleaned from the New Testament are difficult to interpret. Jesus appointed 12 men as his representatives (Mark iii. 14); their number, corresponding to that of the patriarchs, suggests that they were intended to be prince-rulers of the new Israel (*see* APOSTLE). The number was preserved, after the defection of Judas, by the appointment of Matthias (Acts i. 26). At some stage the title "apostles" applied to these men was extended to others, such as Paul (I Cor. ix. 1), Barnabas (Acts xiv. 14), Adronicus and Junias (Rom. xvi. 7). The apostles also ordained seven men to assist them (Acts vi. 1–6); these may possibly have been the first elders or presbyters who formed a kind of council with the apostles in Jerusalem (xv. 2), and elders were appointed in local churches (xiv. 23). These elders were on occasion called *episcopoi*; *i.e.*, overseers (guardians) or bishops (xx. 28). From the Pauline Epistles there emerges the picture of Paul himself as an apostle with plenary authority; under him there were subordinate missionaries such as Timothy (I Thess. i. 1), while in the local churches there were overseers (or bishops) and deacons (Phil. i. 1). In the Pastoral Epistles, which many scholars regard as late and non-Pauline, the threefold hierarchy of bishops, presbyters (or elders) and deacons seems to be established (I Tim. iii. 1–13, v. 1, 17–19; Tit. i.).

Difficulty in relating and interpreting these facts arises from the uncertainty as to whether or not it is function rather than order that is in mind, whether all presbyters were *episcopoi* or only some of them, and what the link between them and the apostles was considered to be. Various theories have accordingly been propounded. It has been argued (1) that authority passed from the apostles to the presbyters and that the institution of bishops was a usurpation of that authority; (2) that bishops came into existence as a distinct order by the uniting in particular localities of apostolic men such as Timothy and Titus; (3) that bishops were created by the elevation of one presbyter in each locality to the

position of president, possibly by apostolic ordering.

The emergence of the threefold order is attributed by many to apostolic initiative, and it is closely associated with the idea of apostolic succession; *i.e.*, the belief that the bishops are the successors of the apostles. Such a view would seem to be expressed in the last quarter of the 1st century by Clement of Rome in his Epistle to the church in Corinth. Of the various factors contributing to this outcome, three may be listed as especially important. First, there was the organization of the Jewish synagogues. This consisted of a collegiate body known as a Sanhedrin (*q.v.*; Gr. *gerousia*), composed of elders or presbyters under a president. The Palestinian Sanhedrins seem not to have had regular presidents, but the head Sanhedrin at Jerusalem had one *ex officio* in the high priest. This arrangement is closely parallel to that which obtained in the Christian church. Second, there was the constitution of the church in Jerusalem. After the martyrdom of James, the son of Zebedee (Acts xii, 2), the 12 were dispersed and James, the brother of Jesus, became president of a council which included presbyters (Acts xv, 6 and 13). Here there is a double parallel with the Jewish Sanhedrin under the high priest and with the bishop and his presbyteral council which is found later in all centres of Christianity. Third, the liturgical gatherings of the local community required a celebrant at the Eucharist, and it is reasonable to suppose that the one performing this task should be regarded as in some sense pre-eminent. A combination of these various influences provides a possible explanation of the emergence of the bishop as the chief liturgical minister of the early church.

A summary of the bishop's functions is to be found in the consecration prayer preserved in Hippolytus' *Apostolic Tradition* (*c.* 217):

> Grant unto this thy servant whom thou hast chosen for the episcopate to feed thy holy flock, and to exercise the High-priesthood before thee, without blame to serve thee day and night, unceasingly to propitiate thy countenance and to offer the gifts of thy holy Church; endued with the high priestly spirit to have power to forgive sins according to thy command, confer orders according to thy precept, and to loose every bond according to the authority thou didst give unto the apostles, and to be well-pleasing unto thee in meekness and cleanness of heart.

In the course of time, circumstances compelled him to delegate many of these functions, but he still remains ideally the chief shepherd, the guardian of orthodoxy and the centre of unity.

**Presbyters or Priests.**—As mentioned above, the account of the appointing of the seven (Acts vi, 1–6) may refer to the institution of the first presbyters. The reason for holding such a view is the apparent dependence of the passage in Acts upon that which records the appointing of the 70 elders by Moses (Num. xi). In both there is a "murmuring," the selection of a specific number of men and a reference to the Spirit vouchsafed to them. If this interpretation is not accepted, then there is no account in the New Testament of their first institution; on the other hand, if it is accepted, this does not preclude recognition of the influence of such existing bodies as the Jewish Sanhedrins.

Although the presbyterate eventually formed the backbone of the church, insofar as its members became the parish priests of the medieval and modern periods, in the first centuries it is not easy to differentiate it from the episcopate, because, with the exception of ordination and, in the west, confirmation, a presbyter could perform all the functions of a bishop. Nevertheless he did so as the bishop's deputy. "Let that Eucharist be considered valid," states Ignatius in his Epistle to Smyrna (*c.* 114), "which is under the bishop or him to whom he commits it." The presbyter therefore taught, baptized and celebrated only insofar as he had the bishop's express permission to do so.

The presbyter was subject to the bishop, who could call him to account, whereas he and his fellow presbyters could not censure their superior. At the same time, the presbyters did assist in the government of the church, forming a kind of senate or council under episcopal presidency. It was indeed seldom that a bishop acted without seeking their advice, and so in the ordination prayer of the *Apostolic Tradition* the petition is made that the presbyter might be filled "with the spirit of grace and counsel . . . and govern thy people with a pure heart."

**Deacons.**—According to the traditional view, the seven of Acts vi were the first deacons, and indeed in later years it was a widespread custom to limit their number to seven in any one city. The title however is not used in that passage which, as argued above, may rather refer to the first presbyters, in which case conjecture is the only method of approaching the origin of the diaconate. The Christian ministry is generally regarded as the organ of the continuing ministry of Christ in his church. According to Mark x, 45, "the Son of man came not to be ministered unto, but to minister" (literally "to be a deacon"). So Paul, as an apostle of Christ, says, "I magnify my ministry" (literally "my deaconing"; Rom. xi, 13). The wholeness of Christ's ministry, undifferentiated in Christ himself, was gradually divided between the three orders. Hence Paul addresses the Christians at Philippi "with the bishops [or overseers] and deacons" (Phil. i, 1). Whereas this statement may refer to functions rather than to distinct orders, by the time of the Pastoral Epistles the diaconate, embodying the principle of Christ's service, is a separate office and a list is given of the virtues required in any candidate (I Tim. iii, 8–13). The deacon thus appears as the bishop's right-hand man and a 4th-century document refers to him as the ears, eyes, heart and mouth of the bishop.

The deacon was the main channel of communication between the bishop and the laity. All offerings were made through his hands and he acted, under the bishop, as the steward of church property and almoner of charitable undertakings. It was his task to give a list of the sick to his superior. He examined the letters commendatory carried by visiting Christians and was frequently entrusted with embassies to foreign parts. He acted as a disciplinary officer under episcopal jurisdiction; he had to reprimand offenders and to deal with the less complex cases that came up for adjudication. His disciplinary duties overlapped with his liturgical, for at the Eucharist he was responsible for the maintenance of order. He stood by the door to prevent the entrance of unbelievers. At the actual celebration, the deacon read the gospel, summoned to prayer, dismissed the catechumens and penitents, presented the offerings of the people, gave the signal for the kiss of peace, administered the chalice and carried the reserved sacrament to the absent.

**Development.**—The threefold ministry was not initially a graded hierarchy; that is, a series of offices through which an individual might advance. A deacon might remain a deacon all his life. This was because the various orders were regarded as functions rather than as offices; for the harmonious progression of the church's life all were necessary. This understanding arose in part from the conception of the church as an organism that required for its life and witness both the continuing ministry of Christ and a structure visible to all. The threefold ministry has continued up to the present day in many churches, although both its authority and its necessity were called in question at the Reformation.

(J. G. Da.)

## THE MINISTRY IN PROTESTANTISM

Throughout the middle ages the threefold ministry of the church in the west was taken for granted, although the great development of the papacy during this period introduced an important new factor which sometimes created tension between various parts of the church. The situation was, however, radically changed with the emergence of the Protestant Reformation of the 16th century. The question of the nature of the ministry was not at first in the forefront of the attention of the Reformers, but once the authority of the papacy was challenged it was inevitable that the authority of the ministry which was bound up with the papacy should also be challenged and its nature redefined. The problem became inescapable when the question of the ordination of ministers who would not accept the papal obedience arose.

**Lutheranism.**—What moved Luther to challenge the authority of the papacy was not, in the first place, a lack of conviction about the validity of papal claims but his rebellion against the understanding of the nature of the gospel implied in Roman Catholic teaching and practice about indulgences, which was prompted by his experience of penitence, forgiveness and justifica-

tion by faith. It was this, in its turn, which led him to rethink the doctrine of the church and to state his characteristic teaching about the priesthood of all believers, with its implied denial of the hierarchical ministry described above.

The intention of Luther was to reassert the ministry of the whole church as a community with a mission to the world. Luther believed that the sphere of faith's works was worldly society and its order and this meant that the church moved out of the cloister into ordinary life. It also meant a new style of life for the ministry. Ministers were encouraged to marry and they were not thought of as a separate order in the church. All that mattered was that they should be duly called (*rite vocatus*). So little attention was paid to episcopal succession that some Lutheran churches did not trouble to retain it when they could have, while others did retain it but attached little significance to the fact (*see* EPISCOPACY).

In practice, however, two considerations prevented the ministry in Lutheran churches from developing fully according to the ideas of Luther. One was the great emphasis laid upon the authority of the secular power, "the goodly prince," and the other was the stress upon the preaching of the Word and the defining of theological truth. These led to an attitude of respect for the state and to a magnification of the office of the minister which hindered the expression of the common life of the church as the communion of saints.

**Calvinism.**—In the Calvinist Reformation the place of the ministry was more explicit. Indeed, some have argued that the Calvinist idea of the ministry has many affinities with that of the middle ages. Unlike Luther, Calvin claimed to be re-establishing the New Testament pattern of ministry, and he and his colleagues tried to assert a degree of ministerial control over discipline and common life, which the Lutherans, with their dependence on the secular authorities, would not have attempted. The authority of the preaching office was magnified at least as much as in Lutheranism. On the other hand, Calvinism taught the parity of ministers and recognized offices of teaching, ruling and diaconate as well as that of preaching. The facts also that congregations had part in the choice of officers and that many elders were not professional ministers helped to modify the clericalism of the Calvinist system and to place the Calvinist churches among the precursors of modern political democracy.

**Independents.**—These latter tendencies were more marked among the Independent, or (as they came to be called) the Congregational, churches and the Baptist churches which emerged in England, and later in New England, in the 17th century. They shared broadly the Calvinist theological viewpoint of the Reformed or Presbyterian churches but differed from them over church government. They emphasized the authority of the particular congregation rather than the presbytery and gave decisive power to the whole membership of the church rather than to the session of ministers and elders. Their conception of the role of the minister in the church was, however, substantially similar to that among the Reformed churches which were more directly under Calvinist inspiration. They emphasized the importance of spiritual gifts in the ministry but, in contrast to Anabaptists and the early Quakers, insisted that learning was no less important than gifts. While they have had little sense of historical continuity, Congregational churches often have achieved an intimacy of personal relation between minister and people for which there are few parallels in Christian history. Throughout the centuries, the role of the minister in the church has grown progressively similar in all churches in the Reformed tradition, just as the offices of eldership in Presbyterian churches and diaconate in Congregational and Baptist churches have grown more like each other.

**Anglicanism.**—The situation in the main church of the English Reformation, the Church of England, is more complicated. The English Reformation was very much a national movement, and, like Lutheranism, it laid great stress on the initiative and authority of the monarch. Anglicans believed that each national church had the right to reform itself in the light of scripture and Christian antiquity. They considered themselves fortunate that, in their situation, they were enabled to do this and to retain the episcopal succession in the traditional ministry. They recognized, however, that Reformed churches on the continent were often in situations where the retention of episcopal succession was impossible. They regretted this, but did not make it a reason for refusing to have intercommunion with them. The position of dissenters within the sphere of their own jurisdiction was different. It was only with the rise of the Oxford movement in the 19th century that many Anglicans began to lay great emphasis on episcopacy as the essential form of apostolic ministry. This emphasis has, perhaps, been increased by the growth of the Anglican communion throughout the world in the 20th century where the link between the bishops, meeting every decade in the Lambeth conferences, is of great importance.

**Methodism.**—The Protestant revivalist movements in the 18th century were led in several countries by individuals of great charismatic power, of whom the chief was John Wesley, and were notably successful in creating large new Christian communities. These communities needed ministry of the Word and sacraments and pastoral care which old-established churches were often unwilling or unable to provide. It was this need, especially as it presented itself in America, together with the convictions that the episcopate and presbyterate were the same office and that the Methodist movement had been vindicated by its fruits, that led Wesley, who was a priest in the Church of England, to take the step of ordaining his own ministers, a practice continued by the large Methodist communities throughout the world. The superintendent ministers of the Methodist Church in the United States are called bishops, but episcopal succession is not retained. In Britain especially, large numbers of trained laymen called lay preachers conduct nonsacramental services in Methodist churches every Sunday and, traditionally, Methodist churches encourage a great deal of spiritual initiative among laymen. In the highly centralized Methodist organization, however, the powers of the ministry remain strong and the centralization, together with the practice by which few ministers stay in any one district for more than a comparatively short time, gives the Methodist ministry something of the character of a religious order.

**Pentecostal and Similar Groups.**—In the 19th and early 20th centuries many new Protestant groups which laid little stress upon a separated ministry emerged in different parts of the world. Some Pentecostal groups in particular attach great importance to charismatic gifts and the ability to evoke experiences of conversion among their leaders, but none to ordination or to office as such. The tendency is, however, as these churches become more well established, for a separated and salaried ministry that receives some formal education to emerge in their midst. The Salvation Army is an important world-wide Protestant organization which does not have offices of ministry in the traditional sense but has large numbers of highly trained officers, who perform many of the functions of the ministry but who are organized on the analogy of a military body.

**Quakers.**—The small but influential Society of Friends does not, except in parts of the United States and in a few mission fields, have an ordained ministry. The duty of ministry of the Word is shared by all members and occasionally individual members are recorded as having a special gift for vocal ministry. Elders are chosen to supervise and guide the corporate spiritual life but do not hold any intermediary position between ordinary members of the society and God.

**20th-Century Developments.**—In the 20th century, most Protestant churches have sought to redefine some of the functions of the ministry, partly in order to meet the needs of the churches in a rapidly changing world and partly in order to draw nearer to each other and to Catholic churches under the inspiration of the ecumenical movement. In a few churches, women have been admitted to full ministerial status, although they still have to struggle for their ministries to win "parity of esteem" with men. In more churches, women have so far been admitted only to the eldership or the diaconate. Many specialized forms of ministry have been developed. The close connection between the ministry and the world of education has long been recognized and there has been vast extension of administrative offices in connection with

the churches and of chaplaincies within the general institutions of society. These are often on an interdenominational basis. The number of ministers who, while ordained in one particular church, are yet the servants of organizations supported by many is steadily increasing. Efforts are being made also to cultivate gifts of ministry among laymen who are not and are not expected to become professional ministers but who are active in the ordinary life of society.

In the Church of South India, a union of former Anglican, Presbyterian, Methodist and Congregational churches, an apparently successful effort has been made to unite ministries deriving from episcopal and nonepiscopal churches in one community. Active discussions with a view to union or intercommunion are proceeding between other episcopalian and nonepiscopalian churches. The principles which most modern Protestants would want to maintain in such discussions are that the one essential ministry in the church is that of Christ, God's Word to man, made known in the Spirit, and that whatever authority the various ministries might have within the churches derives from faithfulness to him rather than from any external source. **MINISTRY, GOVERNMENT.** This term denotes a department of government or group of departments under the control of a minister or the whole body of persons holding political office in the country.

## GREAT BRITAIN

In the United Kingdom the ministry, in the collective sense, consists of the following: (1) ministers in the cabinet; (2) ministers of cabinet rank who are not in the cabinet; (3) ministers of state, parliamentary undersecretaries of state, parliamentary secretaries, financial secretaries and others of equivalent rank; (4) lords commissioners of the treasury (other than the first lord or prime minister and the chancellor of the exchequer) and other government whips; and (5) certain officers of the royal household. They are appointed by the sovereign on the advice of the prime minister; they are, with rare exceptions, either peers or members of the house of commons, and they are considered to hold their offices at the prime minister's disposal; *i.e.*, if the prime minister wishes to change any of them he advises the sovereign accordingly. Also, they go out of office forthwith if the prime minister resigns because of a defeat in the house of commons or at a general election. For this reason the whole ministry, and not merely the cabinet, is said to be "collectively responsible to parliament." However, the ministry as such has no corporate existence, because the decisions are taken by the members of the cabinet, who are formally described as "her majesty's confidential servants" and who are sworn of the privy council.

Many of the modern conventions concerning the ministry were established during the reign of Queen Victoria. From 1783 the sovereign had progressively withdrawn from political controversy, and William IV was almost a constitutional monarch in the modern sense. After 1841 it was clear that the essential duty of the sovereign was to find a prime minister whose party (or, if a coalition was necessary, whose group of parties) could command the confidence of the house of commons. This implied that the whole ministry would be drawn from one party or a coalition of parties. The ministry so appointed was collectively responsible to the house of commons and resigned in a body if defeated there or at a general election. After 1841 the size of the ministry greatly increased. After 1945 the number reached 90. The decrease in the powers of the house of lords resulted in a tendency toward a concentration of ministers in the house of commons, though the Ministers of the Crown act, 1937, made it necessary that some senior ministers and some junior ministers be peers. Apart from the household officers there are usually at least five or six ministers and two or three junior ministers in the house of lords. Consequently, about 70 or 75 members on the government side of the house of commons normally hold paid office under the crown.

A new ministry is assumed to come into existence when a new prime minister kisses hands (of the sovereign at the time of appointment in traditional acknowledgment of the king's favour) or when the existing prime minister, having submitted his resignation, is asked to form a new government.

For the history of the development of the ministry in England and for further details, *see* ENGLISH HISTORY; HOUSEHOLD, ROYAL; PRIVY COUNCIL; CABINET; PRIME MINISTER. *See* also LORD HIGH CHANCELLOR; SECRETARY OF STATE; ADMIRALTY; FOREIGN SERVICE; WAR OFFICE, BRITISH. (W. I. J.)

### BRITISH PRIME MINISTERS

| 1852 | Earl of Derby |
| 1852 | Earl of Aberdeen |
| 1855 | Viscount Palmerston |
| 1858 | Earl of Derby |
| 1859 | Viscount Palmerston |
| 1865 | Earl Russell |
| 1866 | Earl of Derby |
| 1868 | Benjamin Disraeli |
| 1868 | W. E. Gladstone |
| 1874 | Benjamin Disraeli (earl of Beaconsfield, 1876) |
| 1880 | W. E. Gladstone |
| 1885 | Marquess of Salisbury |
| 1886 | W. E. Gladstone |
| 1886 | Marquess of Salisbury |
| 1892 | W. E. Gladstone |
| 1894 | Earl of Rosebery |
| 1895 | Marquess of Salisbury |
| 1902 | A. J. Balfour (earl of Balfour, 1922) |
| 1905 | Sir Henry Campbell-Bannerman |
| 1908 | H. H. Asquith (earl of Oxford and Asquith, 1925) |
| 1916 | David Lloyd George (Earl Lloyd George of Dwyfor, 1945) |
| 1922 | Andrew Bonar Law |
| 1923 | Stanley Baldwin |
| 1924 | J. Ramsay MacDonald |
| 1924 | Stanley Baldwin |
| 1929 | J. Ramsay MacDonald |
| 1935 | Stanley Baldwin (Earl Baldwin of Bewdley, 1937) |
| 1937 | Neville Chamberlain |
| 1940 | Winston Churchill |
| 1945 | C. R. Attlee (Earl Attlee, 1955) |
| 1951 | Winston Churchill (K.G., 1953) |
| 1955 | Sir Anthony Eden (earl of Avon, 1961) |
| 1957 | Harold Macmillan |
| 1963 | Sir Alexander Douglas-Home (formerly earl of Home) |
| 1964 | Harold Wilson |

### LORD CHANCELLORS FROM 1707

For the history of this office, *see* LORD HIGH CHANCELLOR. The following table lists lord chancellors after the Act of Union, 1707, which established one great seal for the United Kingdom. Between 1707 and 1757 vacancies in the chancellorship were twice filled initially by the appointment of a lord keeper (*see* LORD KEEPER OF THE GREAT SEAL). These appointments are indicated in the table by an asterisk. From 1766 all appointments were directly to the lord chancellorship.

| 1964 | Lord Gardiner |

### Chancellors of the Exchequer

The office of chancellor of the exchequer (*q.v.*) dates in name from the 13th century, but in its modern sense from 1714 when the office of lord high treasurer (*q.v.*) was put permanently into commission. The relationship in the 18th and early 19th centuries between the senior commissioner (the first lord of the treasury) and the chancellor of the exchequer is not clear. It seems evident, however, that the chancellorship did not attain its present importance (which arises from the fact that the first lord is normally also prime minister and consequently unable to attend to the day-to-day running of the treasury) until some time after the first quarter of the 19th century.

| 1962 | Reginald Maudling |
| 1964 | James Callaghan |

### Principal Secretaries of State (1685–1782)

The division of the secretariat of state into northern and southern departments dates from 1662, but did not begin officially until 1689. In 1782 the secretariat was reorganized, the southern department becoming the home office, the northern the foreign office. Other departments were added later. Those who were sole secretary for any period are indicated by an asterisk in the list.

| | *Northern* | *Southern* |
|---|---|---|
| 1689 | Earl of Nottingham | Earl of Shrewsbury (duke of Shrewsbury, 1694) |
| 1690 | *Earl of Nottingham | |
| 1690 | Viscount Sydney (earl of Romney, 1694) | Earl of Nottingham |
| 1692 | *Earl of Nottingham | |
| 1693 | Sir John Trenchard | Earl of Nottingham |
| 1693 | *Sir John Trenchard | |
| 1694 | Duke of Shrewsbury | Sir John Trenchard |
| 1695 | Sir William Trumbull | Duke of Shrewsbury |
| 1697 | James Vernon | |
| 1698 | *James Vernon | |
| 1699 | James Vernon | Earl of Jersey |
| 1700 | *James Vernon | |
| 1700 | Sir Charles Hedges | James Vernon |
| 1702 | James Vernon | Earl of Manchester (duke of Manchester, 1719) |
| 1702 | Sir Charles Hedges | Earl of Nottingham (earl of Winchilsea, 1729) |
| 1704 | Robert Harley (earl of Oxford, 1711) | Sir Charles Hedges |
| 1706 | | Earl of Sunderland |
| 1708 | Henry Boyle (Lord Carleton, 1714) | |
| 1710 | Henry St. John (Viscount Bolingbroke, 1712) | Lord Dartmouth (earl of Dartmouth, 1711) |
| 1713 | William Bromley | Viscount Bolingbroke |
| 1714 | Viscount Townshend | James Stanhope |
| 1716 | James Stanhope (Viscount Stanhope, 1717; Earl Stanhope, 1718) | Paul Methuen |
| 1717 | Earl of Sunderland | Joseph Addison |
| 1718 | Viscount Stanhope | James Craggs |
| 1721 | Viscount Townshend | Lord Carteret |
| 1724 | | Duke of Newcastle |
| 1730 | Lord Harrington (earl of Harrington, 1742) | |
| 1742 | Lord Carteret (Earl Granville, 1744) | |
| 1744 | Earl of Harrington | |
| 1746 | *Earl Granville | |
| 1746 | Earl of Harrington | Duke of Newcastle |
| 1748 | Earl of Chesterfield | |
| 1748 | Duke of Newcastle | Duke of Bedford |
| 1751 | | Earl of Holdernesse |
| 1754 | Earl of Holdernesse | Sir Thomas Robinson (Lord Grantham, 1761) |
| 1755 | | Henry Fox (Lord Holland, 1763) |
| 1756 | | William Pitt |
| 1757 | *Earl of Holdernesse | |
| 1757 | Earl of Holdernesse | William Pitt (earl of Chatham, 1766) |
| 1761 | Earl of Bute | Earl of Egremont |
| 1762 | George Grenville | |
| 1762 | Earl of Halifax | |
| 1763 | Earl of Sandwich | Earl of Halifax |

## OTHER COUNTRIES

Throughout the world ministries are the institutional devices that link together the political and administrative fields of government. In some countries they are essentially policy-making institutions; in others their technical work predominates. But in only a few cases are they exclusively political or wholly administrative institutions. Their number and their competence differ from one country to another, but they all have one feature in common: an appointed minister, responsible to the political power, assumes responsibility for the work of one more or less self-contained part of the apparatus of government. The various types fall under three headings—unitary, federal and Communist.

**Unitary States.**—The ministries of modern unitary states in the European tradition are distinguished from their 18th-century predecessors in that they no longer draw their powers from some great hereditary office of state, nor do they (with very rare exceptions) have simple territorial jurisdiction and competence. They have instead developed out of the five great departments of state that are to be found in every civilized community: foreign affairs, justice, finance, defense and war, and internal affairs.

Ministries of internal affairs possess the residual powers of government and in all unitary states it is normal constitutional practice to regard powers not explicitly assigned to or assumed by another central authority as falling under the jurisdiction of the ministry of the interior or internal affairs.

During the 19th century this ministry covered a very extensive field of government; e.g., transport, highways, education, trade, agriculture, church affairs, law and order and the police powers. The modern growth of public services resulted in some of these fields assuming such importance that they were first split off from the ministry of the interior to become special departments, and later separate ministries. By the 1960s virtually all modern unitary states had separate ministries of education, agriculture, transport, trade, etc.

A third category of ministries is to be found in some countries; these are the social ministries that have emerged as the result of pressures for government-organized welfare schemes. Among these are ministries of national insurance, pensions, social security, health and so on.

The status of ministries was influenced by the political movements of the 19th century. Whereas under the absolute monarchs and emperors the heads of ministries were directly responsible to the head of the state, the 19th century saw the emergence of the concept of the politically nominal head of state. He appointed ministers, but only in so far as they possessed the confidence of elected legislatures. The constitution of the Orléans government in France (1830–48) under Louis Philippe served as a model for many countries, and when the monarch was replaced by an elected president the tradition of the political responsibility

of ministers to the elected representatives was continued. Thus, the constitution of the French third republic laid down that "ministers are collectively responsible before the Chambers for the general policy of the Government, and individually responsible for their personal acts." This remained true under the fourth and fifth republics.

Nevertheless, the 20th century saw many exceptions to this rule. Fascist states reversed this doctrine, ministers becoming agents of one man, and in many newly independent states of the post-1945 era a cult of leadership replaced the more traditional western concepts of democratic government, even when the parliamentary institutions remained theoretically the same as those of western unitary states.

The organization of ministries in most modern unitary states in the European tradition differs markedly from Britain in two respects. First, the administrative pyramid does not have at its apex a single, full-time, permanent head comparable to the British permanent secretary. Instead, following the French and European tradition, the ministry is organized on a basis of bureaus and divisions, with a director as the head of each division. The directors are each responsible for a single self-contained branch of the administration with direct responsibility to the minister, the political head. This is a continuation of the old tradition of the collegial direction of administrative boards. Second, in the absence of a permanent secretary, the work of policy formation and advice is shared between the directors and the minister's private office, his cabinet. His cabinet has far more extensive powers than the British minister's private office and is also considerably larger. Members of the minister's cabinet are appointed by the minister and hold office during his tenure; they are mainly chosen from younger civil servants, a few political aspirants and technical advisers. This cabinet forms the minister's private brain trust, as well as acting as his political and parliamentary secretariat.

Sweden is an exception to these general rules governing the organization of ministries in modern unitary states. The ministry is very small, and is essentially comparable to the minister's private office or cabinet mentioned above. The great bulk of administration is hived off to special boards, each with its own director and each possessing statutory powers and duties prescribed in a royal letter of instruction. The ministry, as such, is therefore relieved of all detailed administrative work and acts as the policy- and decision-making institution for one of the main branches of government. The Swedish system is the oldest unchanged administrative structure in the world.

**Federal States.**—The most striking feature of the organization of federal states is the relatively restricted field of government covered by the central ministries. This is a direct consequence of the nature of the federal state in which a written constitution prescribes with varying degrees of detail the powers to be vested in the federal government and the powers to be exercised by the constituent states. In Switzerland there are only seven ministries: the political department (foreign affairs), the department of the interior, the department of justice and police, the military department, the department of finance and customs, the department of public economy and the department of postal service and railways.

Similarly, in the United States there are only ten central departments. But in this case administrative expediency has led to the growth of a large number of agencies, boards and commissions responsible for the detailed administration of various technical branches of government, created *ad hoc* by the federal legislature or by the president. Their responsibility to the executive varies a good deal, but it is not without significance that they have become widely known as the "headless fourth branch of government."

In some federal states the distinction between federal and state matters is blurred by the concept of concurrent powers; thus in the German Federal Republic the ministry of foreign affairs exists only at the federal level, there are some ministries, *e.g.*, for education, which only exist at the *Land* (state) level, and there are some ministries, such as those of justice and the interior, which exist at both levels.

Two other points of federal organization need to be noted. First, except for those federations of the Commonwealth of Nations which have adopted British parliamentary practice (*e.g.*, Canada, Australia, India), the ministers are normally in a position of relative weakness vis-à-vis the head of the executive. In the United States it is the president who appoints the heads of the departments and they retain office at his discretion. They cannot be members of the legislature and are not independent political figures in their own right. Similarly in the German Federal Republic "The Federal ministers are appointed and dismissed by the Federal President on the recommendation of the Federal Chancellor . . . The Federal Chancellor determines, and is responsible for, general policy. Within the limits of this general policy, each federal minister conducts the business of his department independently and on his own authority."

Secondly, although the head of the executive branch in many federations dominates and overshadows his cabinet colleagues, the federal legislature plays a more important role in approving who may be appointed to cabinet office than is the normal practice in unitary states with parliamentary systems of government. The president of the United States, for instance, can appoint to cabinet office only "with the advice and consent of the senate," and his proposed nominations are subjected to searching scrutiny by the appropriate senate bodies. In Switzerland each of the seven ministers (the federal councillors) is elected at a joint session of the two houses of the legislature for four years, the life of the legislature itself. Switzerland also offers a unique example of a rotating presidency. One federal councillor is elected president for one year by the assembly and another is elected vice-president. Neither may be reelected to the same position. The collegial responsibility of the federal councillors is further emphasized by the constitutional provision that "decisions shall be in the name of and authority of the Federal Council as a whole."

In all federations there is an informal convention that ministers or cabinet officers should to some extent be chosen to represent the major political and territorial interests of the various constituent states.

**Communist Countries.**—The nature of Communist doctrine concerning the organization and structure of the state involves three differences from those countries considered so far. In the first instance, although many Communist countries are officially styled federations, the constituent elements have little or none of the constitutional autonomy possessed by federal units in other countries. This means that there is a good deal more subordination of the republican (state) ministries to the federal ministries than elsewhere. In the U.S.S.R., for instance, there are three types of ministry: the all-union ministry, which exists only at the federal level; the union-republican which exists at both the federal and the republican level; and the republican ministries which exist only at the level of the republics. Furthermore, there are ministries also at the level of the autonomous republics, but these are essentially subordinate agencies of the republican or union-republican ministries at the level of the union republic.

In the second place, since the state effectively controls all economic activities, ministries in Communist countries are to be found with titles and fields of operation unknown elsewhere. For instance, in the U.S.S.R. at either the all-union or the republican level, in addition to the ordinary type of ministry such as the ministry of defense, justice or foreign affairs, there are to be found technical ministries for the automobile industry, machine building, heavy machine building, paper and wood products industry, building of enterprises for the metallurgical and chemical industries, instrument-making and automation devices, etc.

Finally, the ministers themselves are not strictly comparable to those to be found in other countries. They are very frequently technicians and seem for the most part to be career specialists. They have no independent political standing and in many cases they do not even appear to rank very high in the Communist party organization. Their tenure of office is uncertain, due to the freedom with which, in the U.S.S.R., ministries themselves are created, amalgamated or abolished. The result of this ministerial technocracy is that the council of ministers in the U.S.S.R. is of less

significance as a policy-making organ than it is in other countries. Its senior members tend not to hold ministerial portfolios at all, but simply serve as first vice-chairmen; and it is believed that the full council of ministers only rarely discusses issues of policy, which are instead determined by a restricted group of nondepartmental ministers in conjunction with the senior party members.

*See* also GOVERNMENT DEPARTMENTS and articles on individual countries. (B. CH.)

**MINK,** a small fur-bearing animal belonging, along with the ferret, stoat and ermine, to the genus *Mustela*, of the weasel family (Mustelidae; *see* CARNIVORE). Mink differ from typical weasels in slight ways associated with their semiaquatic mode of life. The best known species are *M. vison* of North America and *M. lutreola* of Eurasia.

The North American mink measures about 20 to 28 in. in length, 6 to 8 in. of this being tail. Like all weasels, the body is long and slender; the legs short; the neck long and flexible; the head broad; and the ears short and rounded. The deep, rich brown pelage consists of a dense, soft underfur overlaid with dark, glossy, almost stiff, guard hairs; one of the most highly prized of all furs, it has long been a luxury fur of commerce.

Mink are accomplished swimmers and able fishers. They forage for food commonly at night. Besides fish, their diet includes frogs, muskrats, crustaceans, eggs, birds, mice, rats and poultry. Few mammals are as voracious and bloodthirsty. Mink are evil-smelling creatures, the stench being produced by anal glands. But unlike its cousin the skunk, the mink cannot spray its vile-smelling substance; it deposits it in droplets. Mink live along streams, rivers, ponds, lakes and the sea coast. They are equally at home on dry land and, although they prefer forested areas, are less inclined to climb trees than most weasels. The hunting territory of a family of mink will include several square miles. Usually the den is the bank burrow of another animal—a hollow log, a crevice among rocks or commonly a muskrat house whose builders were devoured by the mink. The den is a temporary home, and a few days later the family moves to other quarters. The family unit disperses in late summer, each member establishing a new territory. The larger males may travel extensively at this time. Breeding takes place from midwinter to spring, one male mating with several females, and eventually remaining with one. The four to eight young are born after a gestation of 39 to 76 days, spring pregnancies being shortest. The young are born blind and covered with fine hair. They are breast fed at first, but even before their eyes open—at five weeks—they are eating meat.

In the U.S.—mostly in southern states—mink are raised commercially on mink farms or ranches. The female is of a savage disposition, and in captivity she often kills her young when she becomes excited. Controlled crossbreeding has led to the production of many mutant colours of fur. However, except for the rarer mutant colours, the fur of wild mink is more valued than that of "ranch mink." Few animals—large birds, foxes—prey on mink; trappers and disease account for most deaths. Mink formerly occurred over the United States excluding the southwest, and throughout Alaska and Canada excluding the barrens of the north. They are now rare in the southern parts of this range.

NORTH AMERICAN MINK (MUSTELA VISON)

The European mink resembles the North American species but is smaller, measuring 15 to 18 in. in length. Formerly it occurred over northern and central Europe but, as in North America, has become rare in the southern parts of this range.

A very large species, *M. macrodon*, once occurred along a limited area of the coast of New Brunswick and Maine. It became extinct about 1860, and only a few bones and faded skins remain. *See* also FUR: *Fur Farming*. (K. R. KN.)

**MINKOWSKI, OSKAR** (1858–1931), German clinician and physiopathologist who discovered that lack of endocrine pancreatic secretion produces diabetes, was born in Kovno, Russia, on Jan. 13, 1858, but became a naturalized Prussian in 1872. He studied at the *Gymnasium* in Kovno (1867) and at Königsberg (1875), then studied medicine in Königsberg and Freiburg, graduating from Königsberg in 1885. Minkowski was assistant to Bernhard Naunyn at Strasbourg and later professor of medicine at Breslau, presiding also over the German Insulin committee.

Minkowski discovered that acids are eliminated in the urine combined with ammonia, and found that β-hydroxybutyric acid is the cause of diabetic acidosis and the decrease in sodium bicarbonate in blood plasma. In 1886 he removed the liver from birds and demonstrated that this organ is the site of formation of uric acid (from ammonia and lactic acid or amino acids) and of bile pigments. In 1889 he discovered that extirpation of the pancreas causes diabetes. He had removed the pancreas from a dog so that Joseph von Mering (*q.v.*) could observe whether certain fats could be absorbed without the action of pancreatic juice. He noticed that the animal passed large quantities of urine, which on being analyzed was found to contain glucose. This discovery was published by Mering and Minkowski in 1889.

Later Minkowski made a profound study of pancreatic diabetes, which he correctly interpreted as resulting from suppression of the then-unknown pancreatic hormone. He also published work on acromegaly, familial hemolytic jaundice, the esophageal pulse, gout, etc.

Minkowski died on July 18, 1931, in Wiesbaden. (B. A. H.)

**MINNEAPOLIS,** the largest city in Minnesota, U.S., seat of Hennepin county and port of entry, is situated on the 45th parallel by the Falls of St. Anthony at the head of navigation on the Mississippi river, about 350 mi. N.W. of Chicago. Contiguous on the south and east to St. Paul (*q.v.*), which is often referred to as its twin city, its land area (56.5 sq.mi.) lies on both sides of the river but has developed mainly on the west over an undulating glacial plain contained in the angle of the Minnesota and Mississippi rivers. Within the city limits are 22 lakes and lagoons, and in the suburban area to the west lies Lake Minnetonka, 12 mi. long with 110 mi. of irregular shore line. Its outlet, Minnehaha creek, flows eastward along a residential boulevard and then drops 50 ft. over an escarpment at Minnehaha falls, immortalized by Henry Wadsworth Longfellow in his *Song of Hiawatha*. St. Anthony falls, now flowing smoothly over an apron or cut-off wall, lies in the heart of the milling district whose massive and irregular skyline seems a symbol of the proverbial plenty of the midwest. The handsome stone arch railroad bridge, built in 1881, and three general traffic bridges add interesting perspectives to the scene. Of the many bridges over the river, creeks and lakes, some have great architectural beauty.

**History and Industrial Development.**—The first recorded white visitor was the French Franciscan missionary, Father Louis Hennepin (*q.v.*), who named the falls in 1680. An adventurous traveler, Jonathan Carver (*q.v.*), came to the area in 1766. The falls provided power for a mill which in 1823 ground coarse flour for the soldiers at Ft. Snelling, built above the confluence of the Minnesota and Mississippi rivers, and in 1849 the same cataracts turned the first commercial sawmill. The village of St. Anthony on the east side of the falls was incorporated in 1855. Meanwhile, settlers, mainly from the eastern states, poured in and occupied U.S. military-reservation land mostly on the west side of the

river. In 1855 the government gave these illegal squatters patent rights and a new village was incorporated in 1856. It derived its name from *minne* (a Sioux word meaning "water") and the Greek *polis* (meaning "city"), with a euphonic *a* added in between. St. Anthony was chartered as a city in 1860 and Minneapolis in 1867; in 1870 the population of Minneapolis was 13,066 and St. Anthony, 5,013. The two cities were amalgamated under the name of the larger in 1872.

During these years sawmills buzzed on both sides of the river and by 1859 about 31,000,000 ft. of lumber were shipped from St. Anthony in addition to the timber which was marketed locally. The lumber business reached its height in 1899 when logs from the seemingly inexhaustible forests of the north jammed the river. As wheat-growing in the northwest increased, flour-milling superseded lumbering as the leading industry (the last lumber mill closed in 1919), and a new milling process involving the "middlings purifier," which improved the quality of flour made from spring wheat, made Minneapolis known by 1885 as "the flour city of the United States." Railroads radiating from the city were completed in the late 19th century, multiplying connections with Chicago and the south and with the east through Sault Ste. Marie. These lines brought favourable transportation rates, but after World War I lower freight rates via the Great Lakes shifted much of the export flour trade to Buffalo, N.Y., though Minneapolis remained the headquarters for five large milling companies. Along with the flour, but somewhat separately, developed the grain trade, stimulated in 1881 by the organization of the chamber of commerce, and between 1879 and 1885 Minneapolis advanced from ninth to first place among the primary wheat markets of the country, a position it had not lost in the second half of the 20th century. The Minneapolis Grain exchange is probably the world's largest cash grain market. Two other leading industries of Minneapolis were established in the 1850s: the manufacture of agricultural and railroad machinery and the manufacture of linseed oil from flax of the surrounding country.

The history of Minneapolis was marked by two spectacular events. In 1869 the falls, yielding to a geological fault and overuse by man, threatened collapse, jeopardizing the whole economy of the city. With federal aid, the vital water power was restored by an apron which is still intact. In 1878 an explosion of a major mill destroyed half the milling district and killed scores of workmen. This resulted in intensive research on dust control in mills.

The leading industries of the twin city industrial complex are food products, printing and publishing, machinery, paper and metal products, apparel and transportation equipment, which, with the addition of precision instruments, are also the leading industries of Minneapolis, where an industrial park was developed along the Minnesota river. The city is also the retail shopping centre of the area.

**Population and Urban Growth.**—After 1880, which began the decade of largest population growth, the dominant foreign-born group was Swedish, followed by Norwegians and Germans. Representative nationalities from southern and eastern Europe increased proportionately between 1900 and 1920 though remaining small in number. In 1940 less than 15% of the population was foreign born and in 1950 the percentage was 9.4.

The population of Minneapolis grew steadily from 46,887 in 1880 to 521,718 in 1950. By 1960, however, movement to the suburbs had caused a drop in population of the central city to 482,872. (For comparative population figures *see* table in MINNESOTA, *Population*.)

The city became the centre of a standard metropolitan area of 525 sq.mi. and a population of more than 800,000 in 1930, and in 1950 of a land area of 1,721 sq.mi. with a population of more than 1,000,000.

An area of five counties (Anoka, Dakota, Hennepin, Ramsey and Washington), with a population of 1,482,030, was designated in 1960 as the Minneapolis-St. Paul standard metropolitan statistical area. Among the small older towns of the area are Stillwater on the St. Croix, where lumber manufacture began in 1844, and Anoka, north of Minneapolis, also an early lumber town. The eight townships and villages of the Minnetonka lake district, an area famous during the 1880s and 1890s for fashionable summer resorts, have become year-round communities. South St. Paul is a typical industrial satellite with meat-packing the dominant industry. Middle-class suburban communities have grown rapidly, and St. Louis Park, Richfield (*qq.v.*), Edina and Bloomington, lying contiguous to Minneapolis, showed marked increases in population between 1930 and 1960.

**City Planning.**—Civic improvement and development, begun abortively in 1917, was renewed, and by mid-20th century the face of the downtown area was remarkably changed by the erection of impressive new buildings, both public and private, and by the razing of the blighted area in the heart of the city. Some architectural landmarks are the Ninth Federal Reserve District bank (established 1915), designed in 1924 by Cass Gilbert, with 12 stories since added; the Foshay tower, built by a utilities baron in 1929 in the form of a shaft 447 ft. tall; and the First National bank building, built in 1955.

In 1917 river improvements begun in 1894 were completed to bring navigation into the heart of the city, and in 1948 the federal government began the upper harbour project with the purpose of bringing barge traffic above the falls. Ten trunk-railroad lines serve Minneapolis, and Wold-Chamberlain international airport is about 10½ mi. S. of the city loop.

**Culture and Recreation.**—The Minneapolis campus of the University of Minnesota (established 1851), on the river, in the southeast part of the city, is the centre for many of the cultural activities of the community. The Minneapolis Symphony orchestra, founded in 1903, performs there in Northrop Memorial auditorium, where concerts, ballets and lectures are also held. The university radio station gives cultural broadcasts, and an educational television station was launched in 1957 with the support of community institutions. The Municipal auditorium, built in 1927, seats 10,000 and the Metropolitan Sports stadium in Bloomington, built in 1956, has a capacity of 35,000. The Minneapolis Institute of Arts has been housed since 1912 in a neoclassical building owned and operated by the Society of Fine Arts, incorporated in 1883; the Walker Art centre, built in 1927, specializes in contemporary art. The activities of the American Swedish institute, housed in a late-19th-century mansion, are devoted to the cultural relations of the two countries.

Numerous trade and professional schools include Dunwoody institute, a leading vocational school founded by private endowment in 1914. Augsburg College and Theological seminary (Lutheran, 1869) is a four-year liberal arts college. The public library, its modern building opened in 1961, was enriched in 1885 through an amalgamation contract with the Minneapolis Athenaeum, a private subscription library incorporated in 1859. The Hennepin county library extends the work of the city institution into the surrounding area. A science museum and planetarium are connected with the library. A historic site is the round tower at old Ft. Snelling, south of the city.

Though the largest number of church congregations is Lutheran, all denominations as well as several independent evangelistic sects are represented. The Basilica of St. Mary (Roman Catholic), completed in 1915, was built in Renaissance style. The city is famous for churches representing various styles of 20th-century architecture.

Early in its history influential citizens of Minneapolis realized the beauty and recreational possibilities of the lakes. A park board was created by the state legislature in 1889, and a system of tree-shaded boulevards and parks, including historic Minnehaha park, has been maintained, extending with the growth of the suburbs into the county. The gateway to a great sports and resort area to the north, Minneapolis is conscious of the out-of-doors, and day camps, skating rinks, ski jumps and swimming facilities are numerous.

An annual summer event is Aquatennial week, featuring aquatic sports and a parade of floats. (MA. C. R.)

**MINNESINGER,** the generic name by which the German lyric poets of the 12th and 13th centuries are known. Strictly speaking, and in the usage of Middle High German poets them-

selves, the term *Minnesang* denotes only songs of love (*Minne*) written in the service of the ideal of *amour courtois*, or courtly love (*q.v.*), but it has come to be applied to the whole body of lyric poetry of the period, *Spruchdichtung* (political, moral and religious poetry) as well as *Minnelyrik*.

The songs of *amour courtois*, like the concept itself and the court culture from which it sprang, came to Germany either direct from Provence or through northern France. The minnesinger, like their Romance counterparts, usually composed both words and music and performed their songs in open court, so that their art stood in an immediate relationship to their public. Some were of very humble birth; at the other end of the social scale were men such as the emperor Henry VI, son of Frederick I Barbarossa. The majority, however, were *ministeriales*, *i.e.*, members of the lower nobility, who depended for their livelihood on court patronage, and from the vicissitudes of such an existence come many of the motifs in their poetry. In form, the lyrics follow in the main the tripartite structure taken over from the Provençal *canzo:* two identical sections (known individually as *Stollen* and collectively as the *Aufgesang*) followed by a third section (*Abgesang* —the terms derive from the meistersinger, *q.v.*), the formal ratio between *Aufgesang* and *Abgesang* being variable. On a larger scale is the *Leich* or lyric lay, an aggregation of short strophic elements (versicles) often arranged in an antiphonal pattern derived from the liturgical sequence. These *Leiche* are often several hundred lines in length and many incorporate religious motifs (such as veneration of the Virgin Mary), which are also to be found in the shorter lyrics.

The poems of the earliest minnesinger known by name, the Kürenberger (*c.* 1160—probably a member of the family whose castle stood on the Danube west of Linz), together with a few early anonymous strophes, suggest that, before the force of the new, troubadour-stimulated art was felt, there existed a native tradition of poetry sustained by entirely different attitudes and conventions: instead of the pained worship of a romantic ideal of womanhood, the realistic verses of the Kürenberger show a proud, imperious knight with a woman pining for his love. In Dietmar von Aist (d. *c.* 1170), also an Austrian nobleman, Romance influence begins to make itself felt in the reversal of the roles of the lovers, and by the end of the century, in the work of Heinrich von Veldeke, the Palatinate poet Friedrich von Hausen and the Swiss Count Rudolf von Fenis the art of the troubadours and trouvères (*qq.v.*; as these poets were called in Provence and northern France respectively) has taken control. The climax of the Romance-inspired *Minnesang* is reached in the work of the Thuringian Heinrich von Morungen and the Alsatian Reinmar der Alte (von Hagenau), both of whom flourished at the turn of the 12th and in the early 13th century. Morungen reveals in his love poetry an intensity of feeling and a degree of personal moral involvement unmatched by any of his contemporaries; Reinmar, on the other hand, who spent most of his mature life at the Viennese court, where he instructed Walther von der Vogelweide in the refinements of *Minnesang*, brings to their consummation the formal and conceptual values of the courtly love lyric as an expression of defined social ideals, and appears to the modern reader, as he did already to his own and to immediately succeeding generations, as the most representative poet of "pure" *Minnesang*.

While absorbing much of Reinmar's formal craftsmanship, Walther von der Vogelweide, the greatest lyric poet of the German middle ages, went far beyond the artificial conventions by which the *Minnesang* had been governed, and introduced an element of poetical realism, both in his love poetry and in his political, moral and religious *Sprüche*, or maxims, which in the course of the 13th century was to lead ever further away from the world of courtly ideals. By the time of Neidhart von Reuenthal, a Bavarian squire (d. *c.* 1230), the knight had turned his attention from the ladies of the castle to the wenches of the village. Descriptions of village festivities play a prominent part in his songs, most of which are for dancing; he also frequently introduces himself by name into a poetic situation to which the *pastourelle* motif and the folk song both appear to have contributed. The popularity of this so-called *höfische Dorfpoesie* ("courtly rustic poetry") is shown by the large number of spurious Neidhart-style poems ascribed to him in the manuscripts, and also by the development of the genre by later minnesinger such as Gottfried von Neifen, Tannhauser and Johannes Hadlaub.

While poets like Ulrich von Lichtenstein in his *Frauendienst* (1255) strove by means as fanciful as they were futile to keep the conceits of chivalry alive, others cultivated didactic poetry, which Walther von der Vogelweide, building on the work of earlier *Spruchdichter* such as Spervogel, had already raised to a high level. Prominent among these latter are Reinmar von Zweter, the Marner and Konrad von Würzburg, who all flourished about the middle of the 13th century and who all came to be reckoned by the meistersinger among the "12 old masters." At the turn of the 13th century stands Frauenlob, a poet who by his versatility, his power of rhetoric and his technical refinement points the way to the stylized art of the meistersinger.

There are extant four large codices of minnesinger verse, one compiled in the 13th century, the others in the 14th century; the most famous is the so-called Manesse manuscript, written in the first half of the 14th century and preserved in the university library at Heidelberg. There are also many smaller collections and fragments.

BIBLIOGRAPHY.—*Texts:* the standard collection of poems by minnesinger prior to Walther von der Vogelweide is K. Lachmann and M. Haupt, *Des Minnesangs Frühling*, 30th ed. by C. von Kraus (1950); the *Minnelieder* of later poets are collected in *Deutsche Liederdichter des 13. Jahrhunderts*, vol. i, ed. by C. von Kraus (1952); the most useful concise collection covering the whole range of minnesinger art, *Spruchdichtung* as well as love lyric, is C. Bartsch, *Deutsche Liederdichter des 12. bis 14. Jahrhunderts*, 8th ed. by W. Golther (1928); for editions and studies of individual poets *see* bibliographies in G. Ehrismann, *Geschichte der deutschen Literatur bis zum Ausgang des Mittelalters*, ii, *Schlussband* (1935), and separate articles on them.

**MINNESOTA,** called the "North Star" or the "Gopher" state, a north-central state of the United States. It is bounded north by the Canadian provinces of Manitoba and Ontario, east by Lake Superior and Wisconsin, south by Iowa and west by South and North Dakota. It is the 12th state in size in the union, with a total area of 84,068 sq.mi., of which 4,059 sq.mi. are water surface. It is 406 mi. long and 358 mi. wide. Its name, of Sioux Indian origin, was first applied to the river of that name and probably means "cloudy water." Minnesota was admitted to the union in 1858 as the 32nd state. The state flower is the pink and white lady's-slipper; the state bird is the loon. The state motto is *L'Etoile du nord* ("The Star of the North"); there is no official song, but the university song, "Hail! Minnesota," is popularly regarded as such. The state flag consists of a blue background on which, as the chief element, is placed a white circle, in the centre of which is shown the great seal of the state. The capital is St. Paul.

## PHYSICAL GEOGRAPHY

**Physical Features.**—Minnesota is almost at the centre of the North American continent, lying within approximately 43° 30′ to 49° 23′ N. and 89° 29′ to 97° 13′ W. It extends farther north than any other state of the union except Alaska. Its landscape is distinguished by variety and beauty, the diversity of its terrain being the result of an unusual geological development that was conditioned markedly by the glaciers that four times covered most of the area. The results of repeated glaciation are seen in the thousands of lakes; in the wilderness areas, rolling prairies, fertile valleys, high bluffs, rocky shores and hills that give a richly varied aspect to the scenery; and in the deep, rich soil, ground fine by the passage of ice rivers.

The highest point in the state is at the summit of the Misquah

*Bottom right*: Statues of the legendary hero Paul Bunyan and Babe, his blue ox, at Bemidji

hills in Cook county in northeastern Minnesota, where the altitude is 2,230 ft.; another high point of 1,960 ft. occurs at the crest of the Coteau des Prairies in Murray county in the southwest; and the Mesabi range in St. Louis county rises to an elevation of 2,005 ft. These points were a part of an extension of the Laurentian hills which once extended diagonally across the state from the northeast corner to the vicinity of Pipestone in the southwest corner. The lowest point in the state is the level of Lake Superior, 602 ft.

**Climate.**—Minnesota has a comparatively low mean annual temperature, but its climate is marked by great variation, the average annual range for Minneapolis and St. Paul being 119° (F.). The lowest temperature on record is −59° F. (about −51° C.) recorded at Leech lake in 1903, and the record high is 114° F. (about 45° C.) recorded at Beardsley in 1917. It is seldom that extreme temperatures prevail for more than a few days at a time, and the state has been remarkably free from destructive storms. The cold increases not only from south to north but to some extent also from east to west. The amount of rain decreases from east to west, varying from nearly 31 in. to less than 25 in. at some points, but in all sections there is enough moisture for humid farming. Days of snow cover annually average 120 in the north and 60 in the south. The elevation of the state, its fine drainage system and the dryness of the atmosphere, especially in the winter, help to make it one of the most healthful regions in the world.

**Soil.**—Over the greater part of the state the soil consists of surface drift of glacial origin—a dark brown or black sandy loam of great fertility, adapted to cereal crops. In the east-central part of the state the soil is sandy, excellent for hay and root crops.

**Drainage.**—Glacial action determined the direction and character of rivers, made numerous swamps and created Minnesota's lakes, of which there are more than 11,000. The lakes in the south, which occupy glacial moraines for the most part, are generally broad and shallow, while those in the north, formed by glacial basins scoured in solid rock, are generally deep, with rugged, rocky, pine-covered shores. Most of the larger lakes lie in the forested northern region of the state. Among them are Lake of the Woods and Rainy lake (which are shared with Canada), Red, Mille Lacs, Leech, Winnibigoshish and Vermilion.

The most interesting feature of the glacial epoch is the extinct Lake Agassiz, which the receding ice of the later glacial period left in the Red river valley of Minnesota, North Dakota and Manitoba. As the glacier retreated the lake waters drained northward, leaving Red lake as the most extensive remains of the giant body of water. The resulting flats of the Red river valley provide still another variation to Minnesota's changing landscape.

Minnesota has within its borders more inland water than any other state in the union, 1 sq.mi. of water for every 20 sq.mi. of land. Three of the state boundaries are also at least partly marked by waterways—the northern boundary by the Rainy and Pigeon rivers and the chain of border lakes, the eastern boundary by the St. Louis, St. Croix and Mississippi rivers and the western boundary by the Red river.

The sources of three of North America's great water systems are to be found in the state. From one watershed in the northeast the waters flow southward by way of the Mississippi river into the Gulf of Mexico and northward by way of the Red river to streams that empty into Hudson bay. From another watershed, waters in the northeastern tip of the state flow eastward through the Great Lakes and the St. Lawrence river into the Atlantic ocean. The largest of these three great river systems is, of course, the Mississippi, which, with its tributaries, drains 57% of Minnesota. This largest river on the North American continent begins in Lake Itasca and flows southward through the state, taking in the waters of the Willow, Crow Wing, Prairie, Platte, Elk and Rum rivers before it reaches Ft. Snelling. The largest of the Mississippi's tributaries in the state is the winding Minnesota river, which begins in Big Stone lake on the western border and flows across Minnesota to join the Mississippi near Ft. Snelling. Between Ft. Snelling and the Iowa border the Mississippi gathers in the waters of the Cannon, the Whitewater and the Root rivers, as well as those of the Chippewa and St. Croix flowing in from Wisconsin. The largest of these is the St. Croix, which begins as a small stream in northern Wisconsin and flows southward along Minnesota's eastern border, joining the Mississippi at Prescott, Wis. The Des Moines river, in the southwestern corner of the state, is also part of the Mississippi drainage system, emptying into the Mississippi in Iowa. A few other streams in Rock, Pipestone, Murray and Nobles counties in southwestern Minnesota drain into the Missouri river system and through it finally reach the Mississippi.

The next largest of the three great drainage systems whose headwaters are in Minnesota is the one flowing into Hudson bay. Thirty-four per cent of the state is drained by the waters of the Rainy river and the Red river and their tributaries. The Rainy, forming part of Minnesota's northern boundary, empties northward into Lake of the Woods. The Red river, forming a large section of the state's western boundary, begins at the junction of the Bois de Sioux and Otter Tail rivers and flows northward into Canada. In its rambling course it covers more than 545 mi., draining a rich and fertile valley of more than 100,000 sq.mi. Its main Minnesota tributaries are the Otter Tail, Buffalo, Wild Rice, Marsh and Red Lake rivers. Across the border it is joined by the Roseau river as it travels to Winnipeg where it is joined by the Assiniboine river.

Less than 9% of the state is drained by waters that reach the Atlantic ocean through the Great Lakes–St. Lawrence waterway. The Pigeon river and its headwaters, the chain of lakes stretching westward to North lake, form a part of the northern boundary of Minnesota. The waters of the St. Louis river, emptying into Lake Superior near Duluth, also find their way to the Atlantic, as do the many rugged streams along the north shore of Lake Superior. These small, rapid rivers, full of tumbling falls and cascades, bear such colourful names as Gooseberry, Beaver, Baptism, Caribou, Temperance and Devils Track. Although the various geographical components of Minnesota have all had a great effect on the development of the state, perhaps no single feature did more to shape its early history than did the rivers.

**Vegetation.**—The southern part of the state, before colonists arrived, was open, rolling prairie interspersed with groves of oak and other deciduous timber. A region known as the Big Woods, composed of broad-leaved hardwood trees, extended up the Minnesota valley to the "big bend" (centre at Mankato). The northern part, aside from the Red river valley, was once dense coniferous forest, made up largely of white, Norway and jack pine, but containing also some birch, poplar, maple and oak.

Most of the plants and animals of the north temperate zone are found in Minnesota. Along the streams of the southern part thickets of oak, elm, ash, maple, poplar, basswood, plum and cherry trees are still found in great variety, festooned with grape vines and sheltering small fruits and other shrubs, especially the hazel bush. Scattered over the prairies are strawberries, and the northern woods produce blueberries for many markets. These woods, though subject to intensive lumbering since the beginning of the 20th century, still contain more white pine than is found elsewhere in the country, besides other varieties of pine, balsam, spruce and hemlock. The state flower, the dainty pink and white lady's-slipper, is found in marshes that also shelter the fringed gentian and glow with marigolds and goldenrod in more than 30 varieties.

**Animal Life.**—The French explorers of the late 1600s found beavers working along every stream. Two centuries of Indian fur trade almost exterminated this animal, but in the 20th century, under the protection of the state, the beaver is again multiplying rapidly. Marten, otter, mink, muskrat, bobcat, skunk, raccoon, weasel, wolf, red fox and other fur-bearers have always been numerous. In the sparsely settled parts of the state coyotes and timber wolves, black bears, foxes, lynx and various rodents are prevalent. The gopher (really the striped ground squirrel), which gave Minnesota the name of "Gopher state," is fruitful except where care has been taken to prevent its becoming a nuisance. Deer, moose, bear and elk are the only large game animals; they attract thousands of hunters to Minnesota each year. Game birds —including wild duck, quail, sharp-tailed grouse, upland plover,

prairie chicken and ring-necked pheasant—are abundant; more than 1,000,000 wild ducks and 50,000 deer are killed by hunters each year.

The state's streams and lakes are well stocked with pickerel, pike, bass, crappies and sunfish, and some trout are caught by sportsmen. Minnesota has a larger area in game refuges than any state—5,500,000 ac.

**Parks, Monuments and Recreation.**—Tourism is an important business in Minnesota. The state park system includes 69 natural, scenic, historical and recreational areas of varying size, comprising a total of 100,000 ac. The national park service administers two national monuments, and the Minnesota Historical society administers five state historical sites. Two contemporary movements led to the establishment of the state park system in the late 19th century. The first of these set aside as public parks the major battlefields of the Sioux uprising of 1862. Camp Release, near Montevideo, became the first state park in 1889. The second effort, led by J. V. Brower, preserved as a public area the extensive and unusual wilderness area about Lake Itasca, the source of the Mississippi river. Itasca park, established in 1891, is the state's largest and most famous park. Other major state parks are Gooseberry Falls, Jay Cooke, St. Croix, Scenic, Sibley, Whitewater, Lake Carlos, Interstate, Frontenac, Cascade, Fort Ridgely and Mille Lacs Kathio. Pipestone National monument in the southwestern corner of the state was established in 1937. It is the place where for centuries North American Indians quarried the precious red stone from which they carved their peace pipes. Grand Portage National monument, located on Lake Superior at the northeastern tip of the state, was established in 1958 (it had been designated a national historic site in 1951). It was the great inland depot of the British North West company and the centre of the North American fur trade from about 1770 to 1804. Old Fort Snelling was designated a national historic monument in 1960. (R. W. F.)

## HISTORY

The first European visitors to the territory now embraced in the state of Minnesota found it occupied mainly by two Indian tribes, the Ojibwa (also called Chippewa; Algonkian family), who lived in the heavily wooded northern portion, and the Sioux (more properly Dakota), who made their homes in the more open country of the south and west. Between the two tribes there was almost continual warfare. The first white men known to have entered the state were Frenchmen. Pierre Esprit Radisson and Médart Chouart, sieur de Groseilliers, may have reached Minnesota territory on an expedition overland from Lake Michigan in 1655. It is more probable that they visited Minnesota on a journey southwest from Lake Superior about 1659.

Daniel Greysolon, sieur du Lhut (Dulhut or Duluth), is known to have penetrated the territory southwest of Lake Superior in 1679 as far as Mille Lacs, where he set up the standard of Louis XIV. The following year Dulhut crossed via the Bois Brule–St. Croix route to the Mississippi, where he met a party of three Frenchmen led by Michael Accault. They had been sent up the river by La Salle to make the first exploration of the upper Mississippi. Accompanying this expedition was Father Louis Hennepin, who during his wanderings before meeting Dulhut discovered and named the Falls of St. Anthony, and who later wrote the first published description of the country. Nicolas Perrot, a trader, ascended the Mississippi in 1686 to Lake Pepin, on the east shore of which he built a fort. Again in 1688 he visited the region, and in 1689 he proclaimed the sovereignty of France over it. In 1695 Pierre le Sueur, who had traded on the upper Mississippi for some years, established a post on Isle Pelée (Prairie Island) in the Mississippi between Hastings and Red Wing. In 1700 he ascended the Minnesota river to the mouth of the Blue Earth river near Mankato, whereon he built Ft. L'Huillier.

A period of lethargy followed these early explorations because of the death in 1698 of the energetic governor comte de Frontenac, who had encouraged them, and the absorption of France in the War of the Spanish Succession (1701–14). All French garrisons in the northwest were withdrawn. Not until Sept. 1727 did another French expedition reach the region. Then the sieur de la Perrière landed on the west bank of Lake Pepin and built a fort; the Jesuit fathers who accompanied him established a mission, but both institutions were short-lived. In 1731 a party under P. G. de Varennes, sieur de la Vérendrye, explored the chain of lakes along the northern border of Minnesota, and a detachment under his nephew, La Jémeraye, built Ft. St. Pierre on the north bank of Rainy lake. In the next year the main expedition pushed on to the Lake of the Woods, where, within Minnesota borders, they built Ft. St. Charles, occupied for 20 years, or longer than any French establishment in the territory.

In the treaty of Paris (1763) at the close of the Seven Years' War in Europe, the French ceded to England all their possessions east of the Mississippi except the site on which New Orleans was located; those west of that river they had cautiously ceded to Spain in a secret treaty the previous year.

During the period of the British regime, Jonathan Carver (*q.v.*) was sent out to treat with the Indians, in 1766, by Maj. Robert Rogers, commandant at Michilimackinac (Mackinac). He spent the winter of 1766–67 among the Sioux of the Minnesota valley, and in the spring he traveled to Prairie du Chien, where he joined an expedition under Capt. James Tute sent out by Rogers to find a route to the "western sea." Carver later published a lively account of his travels, which was widely read in Europe.

Another trader of the British period was Peter Pond, a Connecticut Yankee who spent two winters, from 1773 to 1775, on the Minnesota river. David Thompson, who was employed both in trading for the North West company and in determining the location of the 49th parallel, passed through northern Minnesota in the winter of 1797–98. His diaries are the earliest known scientific record of Minnesota topography.

**United States Ownership.**—After the Revolutionary War, the English relinquished their portion of the region (treaty of Paris, 1783) to the newly formed United States. There was no force to expel the English from the northwest wilderness, however, and the British flag remained flying over the trading posts of the North West company in Minnesota until after the War of 1812. This company had been formed to organize systematically the fur trade of the northwest. Its headquarters for the region during the last two decades of the 18th century were at Grand Portage, at the east end of the famous portage between Lake Superior and the Pigeon river.

In 1803 the western part of Minnesota was acquired by the United States as part of the Louisiana Purchase. In 1805–06, at the instance of Pres. Thomas Jefferson, Lieut. Zebulon M. Pike led an exploring expedition up the Mississippi as far as Leech lake and Upper Red Cedar or Cass lake. He visited the main posts of the North West company and took formal possession for the United States. He also negotiated with the Indians for a tract of land at the confluence of the Minnesota and Mississippi rivers upon which, in 1819, the post later known as Ft. Snelling was established. For many years this remained the northwesternmost military post in the United States, and it was also the centre of the fur trade in the region.

In 1816 the North West company's traders were forced out of Minnesota and their posts were taken over by the American Fur company, which was soon doing business throughout the upper valley of the Mississippi.

In 1818 the jurisdiction of Michigan territory was extended to the Mississippi river. Its governor, Lewis Cass, attempted to find the source of the Mississippi in 1820. In 1823 extensive explorations of the Minnesota and Red river valleys were conducted by Maj. Stephen H. Long, and subsequently knowledge of the Minnesota country was extended by investigations of the region by Henry R. Schoolcraft, who discovered Lake Itasca, the source of the Mississippi, in 1832; by George Catlin, whose journey of 1836 took him to the famous pipestone quarry; by Joseph N. Nicollet, whose tours of the late 1830s resulted in the first accurate map of the region; and by Maj. Samuel Woods, who explored the Red river valley in 1849. A settlement grew up about the headquarters of the American Fur company at Mendota, on the Minnesota river opposite Ft. Snelling.

In 1837 two treaties, one with the Chippewa and the other with the Sioux, were negotiated, extinguishing the Indian title to the wedge of land between the Mississippi and St. Croix rivers, a part of the Northwest Territory (*q.v.*), and opening it to settlement. Following these treaties thriving settlements grew up at St. Paul and Stillwater.

**Minnesota Territory.**—In 1849 the bill organizing the territory of Minnesota was passed by congress, and Alexander Ramsey was appointed governor. The first territorial legislature met at St. Paul on Sept. 3 of the same year. By the federal census of 1850 the territory had 6,077 inhabitants, most of whom lived east of the Mississippi or along the Red river in the extreme northwest. Treaties negotiated in 1851 with the Sioux opened to settlement the greater part of the land in the territory west of the Mississippi; and treaties with the Chippewa in 1854 and 1855 extinguished the Indian title to nearly two-thirds of the northern half of the state. Such an unparalleled rush to the new lands took place that a census in 1857 showed a population of 150,037. The lumbering business was booming and building up the towns of Stillwater and St. Anthony (Minneapolis), and St. Paul at the head of navigation on the Mississippi, became the commercial centre of the territory. Other river towns proved prosperous ports of entry from which settlers trekked to the interior, sometimes individually, sometimes by whole colonies transplanted from eastern states.

In July 1857 a convention met and drew up a state constitution, which was adopted the following October by an almost unanimous popular vote. On May 11, 1858, the state was admitted to the union with its present boundaries.

**Statehood.**—Minnesota supplied more than 22,000 men for the Federal armies during the Civil War. Even more important to the state than the war in the south was the defense of its frontier against the uprising of the Indians within its borders. The Sioux felt that they had been deceived and outdone in the treaty of 1851. In 1858 their small reservation was halved and most of the payment went to the traders. Many of the natives resented the government's attempts to make them farmers.

When in the summer of 1862 there was delay in the payment of annuities, bands of the Sioux suddenly began to massacre the settlers in the Minnesota valley. These attacks continued with increasing fury (more than 350 whites losing their lives) until forces under Gen. Henry H. Sibley decisively defeated the Indians under Little Crow, their principal leader, at Wood lake. Three days later 269 white captives were released. Many of the Sioux fled into the Dakota country, but expeditions under Sibley in 1863 and Gen. Alfred Sully in 1863 and 1864 marched against them and drove them beyond the Missouri.

The coming of peace marked the beginning of a new period of rapid growth, the federal census of 1870 showing a population of 439,706 or a gain of 155.6% in ten years. During the same decade railway construction, which had begun with a line between St. Paul and St. Anthony in 1862, reached close to 1,000 mi. The period 1870–80 was one of great discontent among the farmers, and one expression of their feeling was their opposition to certain widespread abuses of the railroads.

A number of regulatory laws, usually called the "Granger acts," passed the legislature. Cases arising out of these acts, and carried to the U.S. supreme court, which decided against the railroads, had far-reaching results in establishing principles of public regulation of common carriers. The railways themselves suffered severely in the panic of 1873, and the farmers were troubled by severe and repeated grasshopper invasions that destroyed the crops over large areas. Despite these setbacks, Minnesota's population increased 77.6% in the decade from 1870 to 1880; settlements spread over the prairies of the west and southwest and down the Red river valley. Many of the newcomers were Scandinavian and German immigrants. Wheat became the great crop of the prairies.

In the north the forests were falling under the organized attack of great lumber companies. Agricultural conditions revived, railroads again were being built, and the basis was laid for steady growth in the following decades.

In 1884 the mining of iron ore was begun on the Vermilion range and in 1890 and 1891 the much larger deposits of the Mesabi range were discovered. With the opening of the Cuyuna range in 1911, Minnesota became the source of most of the United States' iron ore. (J.X.)

Lumbering, flour milling and iron mining were major forces affecting Minnesota's economy in the 19th century and contributed to its industrial and urban development. But other factors were also involved. The combination of agricultural products and fine transportation facilities led to the growth of South St. Paul and Austin as meat-packing centres. The quarries of the St. Cloud area contributed to the growth of the "Granite city." International Falls developed around a by-product of the lumber industry, the manufacture of paper.

During the century from 1850 to 1950 Minnesota's population increased from 6,077 to 2,982,483. By the latter year, more than half of the state's people lived in the three large metropolitan areas of Minneapolis, St. Paul and Duluth.

Minnesota's political experience has been coloured by the rise of a number of strong third parties within the state, and these movements left a heritage of independence that characterizes the voting habits of the people. While the first state officials were Democrats, the Republican party took office in 1860 and remained dominant for a generation thereafter. Challenges from the Democrats and Populists increased toward the end of the century, and in 1898 John Lind, a Democrat, won the governorship. Between 1900 and 1930 Republicans were again in the ascendancy, although their control was less absolute than before. The post-Civil War tradition of the agrarian crusade led by Oliver H. Kelley, founder of the National Grange (*q.v.*), and Ignatius Donnelly was continued in the 20th century by another Minnesotan, A. C. Townley. In 1915 he organized the Nonpartisan league, and for some years it was a strong influence in the politics of the middle west. Another of the league's leaders was Charles A. Lindbergh, Sr., who helped found the Farmer–Labor party after World War I. This party elected Floyd B. Olson governor in 1930 and the party held that office until 1938 when the Republicans returned to power under the leadership of Harold E. Stassen. The Republican party held the governorship for 16 years. A merger of the Democratic and Farmer–Labor parties, effected in 1944, was successful in electing Gov. Orville L. Freeman in 1954, 1956 and 1958. In 1960 Freeman was defeated by Republican Elmer L. Andersen, who lost to Democratic-Farmer-Labor Lieut. Gov. Karl F. Rolvaag in 1962.

In presidential elections Minnesota supported every Republican candidate between 1860 and 1928, except in 1912 when Woodrow Wilson received more votes than William Howard Taft. In the elections of 1932 through 1960 Minnesota was Democratic, except in 1952 and 1956 when Dwight D. Eisenhower carried the state for the Republicans.

## GOVERNMENT

The constitution adopted on Oct. 13, 1857, was frequently amended. A proposed amendment must be approved by a majority of the votes cast at a general election. The legislature is composed of two houses, the senate (67 members) and the house of representatives (131 members), members of the former being chosen for four years and of the latter for two years. The legislature passed a reapportionment bill in 1959, the first such action since 1913. The executive department is made up of a governor, lieutenant governor, secretary of state, treasurer and attorney general, all elected for two years, and an auditor elected for four years.

In 1939 state departments and agencies, with a few exceptions, were placed under the department of administration, constituted as a staff agency of the governor, in all matters pertaining to budgeting and finances, purchasing and contracting, and the care and custody of state properties.

The governor has the power of veto, but any bill he fails to return within three days, if the legislature is still in session, becomes law without his signature. A two-thirds vote of each house is necessary to override the veto. The lieutenant governor presides over the senate and succeeds the governor in case of the latter's death.

*Populations are reported as constituted at date of each census. †Known as Detroit prior to 1940. ‡Township. §Brooklyn township, which includes the population of Brooklyn Park. ‖Mendota township, which includes the population of Mendota Heights. ¶Rose township, which includes the populations of Falcon Heights and Roseville. #Brooklyn township, which includes the populations of Brooklyn Center and Brooklyn Park. ‡Crystal Lake township, which includes the population of Crystal.
Note: Dash indicates place did not exist during census, or data not available.

Two significant constitutional amendments won approval at the polls in 1958, a "home rule" amendment, which encouraged and strengthened home rule and self-government in local communities; and the "four-year term" amendment, which put four-year terms (in contrast with the existing two-year terms) into effect in 1963 for five chief state offices (governor, lieutenant governor, secretary of state, attorney general and treasurer).

The supreme court consists of a chief justice and six associate justices, each elected for a term of six years. There are also 10 judicial districts, each with a district court presided over by from 3 to 14 elective judges. Every county has a probate court, while for the general administration of local justice there are municipal courts and justices of the peace.

## POPULATION

Minnesota is thought of as a state of Scandinavians, and in fact it probably does owe more to Scandinavians than to any other one national group. During the 1880s, when the flood of immigration was at its height, Scandinavians made up half of the foreign-born in the state. Early Swedish immigration was attributed in part to the writings of Peter Cassell, whose series of American letters published in local Swedish newspapers after his settlement in Iowa in 1846 had enormous circulation. The original Swedish immigrants were farmers, and they settled immediately on the land, their main stronghold being in east-central Minnesota. Norwegians originally tended to work in the lumbering industry, then turned to farming in the Red river valley and in the southeastern counties. Danish settlers were chiefly responsible for Minnesota's success as a dairying state. Germans were among the earliest of the national groups to come to the state, and between 1890 and 1900 they led in numbers of immigrants. Finns, Poles and Czechs make up the other largest national groups. The 1850 census enumerated 39 Negroes; in 1930 the number was 9,445, and in 1950 it was 14,022.

The population of Minnesota in 1850 was 6,077; in 1880 it was 780,773; in 1910, 2,075,708; in 1940, 2,792,300; in 1950, 2,982,483; and in 1960 it was 3,413,864, an increase of 14.5% over the population in 1950. The population per square mile in 1960 was 40.6, as compared with 49.6 for the U.S.

Of the 1960 population, 62.2% lived in incorporated places of 2,500 or more, as compared with 54.5% in 1950 and 49.8% in 1940 when these places constituted the urban area. The state's three standard metropolitan statistical areas—Duluth-Superior (shared with Wisconsin), Fargo-Moorhead (shared with North Dakota) and Minneapolis-St. Paul—had a total 1960 population of 1,864,653 (including 45,008 in Wisconsin and 66,947 in North Dakota). Of Minnesota's white population (98.8% of the total), 95.8% were native born and 4.2% foreign-born. Nonwhites compose 1.2% of the total population. Of the foreign-born, more than half were born in Sweden, Norway and Germany.

There were 101.7 females per 100 males in the native white population and 96.0 in the foreign-born; 10.4% of the population was 65 years old or over; and 77.8% of the population 14 years old and over was in the labour force. Of the total number of employed males, 14.4% was engaged in agriculture, 5.5% in construction and 19.5% in manufacturing.

## EDUCATION

General supervision of the state public-school system is the responsibility of the state department of education, and control of the department is vested in a nonsalaried board of education, consisting of seven representative citizens appointed by the governor and approved by the senate. The board's powers are exercised through the state commissioner of education, whom it elects.

As soon as the required standards are met the department metes out state aid in a certain fixed proportion. In addition, there is supplemental aid designed mainly to help the less affluent school districts. There are about 3,000 elementary schools in Minnesota and 670 accredited secondary schools, with a total enrollment of about 650,000. Nearly 30,000 teachers are employed in the public schools, and total state and local expenditures for elementary and secondary education amount to more than $300,000,000 annually. There are a number of junior colleges. Teachers are trained at the college of education at the University of Minnesota and its branches at Duluth and Morris, and at the five state colleges in Mankato (founded 1867), St. Cloud (1869), Moorhead (1887), Bemidji (1913) and Winona (1858).

The largest of the institutions of higher learning is the University of Minnesota, which enrolls about 26,000 full-time students yearly. The university was established under the Territorial act in 1851 and began instruction in 1869. It grants degrees on its three campuses at Minneapolis, St. Paul and Duluth, and is governed under its state charter by a board of regents, 12 citizens of the state elected by the legislature. The university's colleges include the college of science, literature and the arts, the general

college (for general education), the Institute of Technology (including a college of engineering, school of architecture, school of chemistry and school of mines and metallurgy), the college of agriculture, forestry and home economics, the college of education, the school of dentistry, the school of nursing, the medical school, the school of public health, the school of business administration, the law school, the college of pharmacy, the school of veterinary medicine, the university college and the graduate school. The university also conducts schools of agriculture of less than college grade, a teacher-training junior-senior high school, a six-year elementary school and a nursery school and kindergarten. It offers extension and correspondence courses in a wide variety of subjects. The Mayo foundation for graduate study and research in the medical sciences works in co-operation with the Mayo clinic at Rochester. The university library numbers about 2,000,000 volumes.

Privately supported colleges of liberal arts are Carleton (founded 1866) and St. Olaf (Evangelical Lutheran; 1874) in Northfield; Gustavus Adolphus (Augustana Evangelical Lutheran; 1862) in St. Peter; Hamline university (Methodist; 1854), Macalester (United Presbyterian; 1885), St. Thomas (Roman Catholic; 1885) and St. Catherine (Roman Catholic; 1905) in St. Paul; Augsburg (Lutheran Free; 1869) in Minneapolis; St. John's (Roman Catholic; 1857) in Collegeville; St. Benedict (Roman Catholic; 1913) in St. Joseph; St. Mary's (Roman Catholic; 1913) and Saint Teresa (Roman Catholic; 1907) in Winona; Concordia (Evangelical Lutheran; 1891) in Moorhead; and St. Scholastica (Roman Catholic; 1912) in Duluth.

## HEALTH AND WELFARE

The department of public welfare supervises the county welfare programs, which serve more than 100,000 persons. It also maintains numerous institutions, including hospitals for the treatment of the mentally ill, schools for the mentally deficient, sanatoriums for tubercular patients, a school for the blind, a school for the deaf and a hospital for inebriates. The department of corrections, created by the 1959 legislature, operates a division of adult corrections and a division of youth conservation. The former administers a program for the custody, treatment and training of offenders committed by the courts to the state prison at Stillwater, the state reformatory for men at St. Cloud and the state reformatory for women at Shakopee. The division of youth conservation maintains a program for the diagnosis, custody and rehabilitation of youths under the age of 21 who have been adjudged delinquents or criminal offenders. It administers a state training school for girls at Sauk Centre, a state training school for boys at Red Wing and three forestry camps for boys at different locations in the state. The department of employment security assists people to find employment and pays unemployment insurance.

A state board of health, created in 1872, functions through seven divisions: disease prevention and control, medical laboratories, local health administration, environmental sanitation, special services, hospital services and administration.

## ECONOMY

**Agriculture.**—Minnesota has been pre-eminently an agricultural state (though manufacturing is slowly replacing agriculture as the chief source of income). The annual income of nearly $1,500,000,000 in the early 1960s from sale of crops, livestock and livestock products placed Minnesota fifth or sixth among the states in this respect. In production of farm crops Minnesota ranks second among the states in oats, third in corn and fourth in hay; it ranks high also in soybeans, flaxseed, green peas, barley, rye, sugar beets and potatoes. Approximately 20,000,000 ac. are devoted to the cultivation of crops. Apples are the only fruit crop raised commercially to any extent.

The value of all livestock and poultry on farms approximates $675,000,000; horses number about 60,000, cattle about 4,000,000 (including approximately 1,500,000 milk cows), sheep about 1,000,000 and hogs about 3,200,000. Minnesota is one of the great dairy states, leading all the states in butter production (about 400,000,000 lb. annually) and producing also 10,000,000 lb. of milk and about 9,000,000 lb. of cheese. Farmers' co-operative creameries were largely responsible for the growth of dairy product marketing.

Total area in farms is about 33,000,000 ac., with an average farm size of nearly 200 ac.

**Mining.**—Minnesota leads the nation in the production of iron ore, although shipments declined in the second half of the 20th century. The ore comes from three districts, the Vermilion, Mesabi and Cuyuna ranges, named in the order of their discovery and development, all lying in the northern part of the state. About 90% of the ore comes from the Mesabi range, from the first shipment of ore from this range in 1892 to 1950, the Mesabi contributed about 1,500,000,000 tons of high-grade ore. An estimated 1,500,000,000 tons of merchantable ore remains deposited in the three ranges. A great deal of the mining is of the open-pit character. Steam shovels in the mines load the ore on trains that run directly to the docks at Two Harbors or Duluth, where steamers wait to carry it to the steel mills at Chicago, Gary or Erie.

After World War II the production of taconite (*q.v.*) developed rapidly in Minnesota, a commercially feasible concentration process making possible the utilization of low-grade ore. The taconite industry, involving both mining and manufacturing, gave new economic life to northeastern Minnesota, and the state's taconite reserves have been estimated at 24,000,000,000 tons.

The remainder of the state's mineral output is made up largely of quarry products. Minnesota has extensive deposits of granite, limestone, jasper, sandstone, travertine, mica, feldspar and clay. The state ranks third in the production of granite with St. Cloud as the centre of this industry.

**Lumbering.**—During the years following the Civil War, the pine forest resources of the state were intensively exploited. Minneapolis and Duluth owed their rapid growth in the 1870s and 1880s in part to the milling and shipping of lumber. In 1905 production of lumber reached its peak with the cutting of 2,000,000,000 board feet of timber. By then the area's magnificent stands of white pine were nearly depleted and the industry declined rapidly. The mid-20th century saw the state's forest industries rise again, with the production of pulpwood, Christmas trees and other wood products. Scientific forestry practices and new uses for the less valuable timber created by modern manufacturing processes resulted in a larger annual income than was ever obtained from the original forests.

There are two national forests in the state, Superior and Chippewa, with a combined area of more than 4,000,000 ac., and 34 state forests with a combined area of 5,500,000 ac.

**Manufactures.**—Throughout most of its existence, Minnesota has been predominantly an agricultural state. In the mid-20th century, however, its industrialization accelerated, and by 1950 the dollar value of manufactured products exceeded cash farm receipts for the first time in the state's history. First in order of importance is the food industry, including meat slaughtering and packing (concentrated largely in South St. Paul and Austin), grain and feed mills and manufactured dairy products. Minneapolis has long been a principal centre of the flour-milling industry for the United States, and accounts for much of the manufactured output of grain and feed in the state. Water power from the Falls of St. Anthony was the chief factor for Minneapolis taking the lead in milling. By 1870 twelve mills were operating at the falls, and the industry continued to expand until 1916. Thereafter it declined, though remaining very important. The great grain elevators are a feature of the Minneapolis skyline.

The second largest manufacturing industry is that of machinery (other than electrical) and following that in importance are printing, publishing and allied products; chemical products; pulp, paper and allied products; and fabricated metal products.

Growth in development of electric power was tremendous in the period following World War II. The two chief sources were steam power and water power, with a smaller amount derived from internal combustion. The state's first atomic power plant, constructed at Elk river by the Rural Cooperative Power association in co-operation with the Atomic Energy commission, began to

provide electricity for co-op members in 1960. Three types of suppliers of electricity—power companies, municipally owned utilities and rural electric co-operatives—operate in Minnesota. Almost all occupied dwellings in the state are serviced by electricity.

**Transportation and Communications.**—Minnesota is well provided with transportation facilities by water, air and land. Duluth stands at the head of the Great Lakes, and through its port pass most of the iron ore extracted from the Minnesota mines and a large share of the grain grown in the northwest. It is also a receiving port and distributing point for coal and other products for the area. In gross shipping tonnage Duluth ranks second only to New York city. Several railways connect with Chicago while others reach out into the wheat lands of the Dakotas, Montana and western Canada. At the head of navigation on the Mississippi stand St. Paul and Minneapolis.

River transportation was developed early in the state's history, the first steamer reaching Ft. Snelling in 1823, and it continues to be important in Minnesota's transportation system. In 1930 a nine-foot channel on the Mississippi river with attendant locks and dams was opened to traffic, and after that time barge traffic increased steadily. By the early 1960s about 7,000,000 tons of freight were shipped annually on the Mississippi and its tributaries in Minnesota, as compared with 2,500,000 tons in 1949.

Minnesota's first railroad was completed between St. Paul and St. Anthony in 1862 by the St. Paul and Pacific, the road that was reorganized under the leadership of James J. Hill in 1878 and eventually became the Great Northern. From the older centres in Minnesota, tracks reached out to the west, north and south. The Northern Pacific, the first road to connect the state with the Pacific coast, was completed under the guidance of Henry Villard in 1883. By the 1960s Class I railroads in Minnesota operated approximately 8,500 mi. of track.

Air travel is of significance in the state, numerous communities being served by airlines. An amendment to the state constitution passed in 1944 made available state funds to assist municipalities in improving airports; federal funds also are available. A unique feature of the state's aviation activity concerns the wilderness area of Superior National forest. Fear that the increasing number of flights into the area would destroy its wilderness character led the state legislature in 1949 to take steps to control air activity, and in Dec. 1949 an executive order issued by Pres. Harry S. Truman banned flights over Superior National forest wilderness area beginning Jan. 1, 1951.

The state trunk highway system includes 12,000 mi. of mostly paved roads. All highways and roads total almost 125,000 mi. Annual disbursements for the trunk highway system were increased more than 500% in the decade beginning 1950, from $43,000,000 to approximately $242,000,000. Building and maintenance of the trunk highways was financed by taxes on motor vehicles and gasoline, bond issues and federal aid. The trunk system is kept open for motor travel all winter.

There are about 30 daily and more than 300 weekly and semi-weekly newspapers in Minnesota. The Minnesota Newspaper association was founded in 1867, though its membership includes all of the state's newspapers, it is primarily the voice of the weekly press.

Commercial radio broadcasting began in Minnesota in 1922 with station WLAG (forerunner of WCCO); network broadcasting came to the state in 1925. KSTP began experimenting with television cameras in 1939 and brought telecasting to the state on April 27, 1948.

Private experimental telephone lines were run to the Twin Cities in 1877, and the following year the Northwestern Telephone company was operating in Minneapolis. Numerous independent companies sprang up, some of them using the rapidly improving Bell equipment. Eventually, the majority of the companies were consolidated into the Northwestern Bell Telephone company, a subsidiary of the American Telephone and Telegraph company. However, a few independent telephone companies still operate in the rural areas of the state.

The publications of the Norwegian-American Historical Association contain a wealth of material relating to Minnesota, particularly Theodore C. Blegen's *Norwegian Migration to America, 1825–1860* (1931), and *The American Transition* (1940).

Current statistics on production, employment, industry, etc., may be obtained from pertinent state departments; the principal figures are summarized annually in *Britannica Book of the Year*, American edition.

(R. W. F.)

**MINNESOTA, UNIVERSITY OF,** an institution of higher learning with campuses at Minneapolis, St. Paul and Duluth, Minn., was established under the Territorial act in 1851 and began instruction in 1869 (*see* MINNESOTA: *Education*).

**MINNOW,** in North America the name given to a variety of small fishes, especially cyprinids (shiners, for example), mud minnows (family Umbridae) and killifishes (Cyprinodontidae); also, in a general way, to the young of many kinds of large fishes.

*Phoxinus phoxinus*, of the carp family (Cyprinidae), is the minnow of Europe and northern Asia; it is distinguished from the dace and chub, allied cyprinids, by its small scales. A length of three or four inches is usual, but specimens seven inches long are known. In New Zealand and Tasmania fishes of the family Galaxiidae are called minnows.

Mud minnows are related to the pike, from which they differ in having uniformly small, weak teeth. They live in mud or among weeds of sluggish streams and ponds. Among the killifishes, the top minnow or mosquito fish (*Gambusia affinis*) is the best known. It occurs naturally in lowland marshes, pools and lagoons of the south Atlantic and Gulf regions of the United States. It bears live young and is exceedingly prolific. This fish is so effective as a destroyer of mosquito larvae that it has been widely introduced to control mosquitoes. Anglers use all kinds of minnowlike fishes as bait. *See* also FISH; FISHING. (L. A. WD.)

**MINOAN CIVILIZATION:** *see* AEGEAN CIVILIZATION; CRETE.

**MINOAN LINEAR SCRIPTS.** This term denotes the well-developed varieties of writing used by certain Aegean civilizations (*q.v.*) during the 2nd millennium B.C. Like other early writing systems in the near east (*see* CUNEIFORM), this Minoan-Mycenaean type of script had its beginnings in pictography, originating on the island of Crete (*see* CRETE: *Archaeology*). There is no conclusive evidence for more remote outside origin or inspiration, though the latter is an a priori assumption with those scholars who believe in the monogenesis (single origin) of all writing.

**Origins.**—The origins of this script are seen on stone seals dating from the Middle Minoan period (beginning *c.* 2000 B.C.), found on the surface in different parts of Crete, and in early archaeological strata of the palace sites, notably Cnossus and Phaistos. The latter contain seal impressions in clay and tags or tablets of the same material which served the practical purpose of identification. The pictographic origin is still clearly visible in the signs at this hieroglyphic stage (*e.g.*, a double axe, an eye, a cat's head). Yet compared with the complicated word-syllabic stage of Egyptian, Mesopotamian, "Hieroglyphic Hittite," and other early systems, with their mixtures of ideographic and phonetic values of signs, classifiers and complements, Minoan writing early developed an everyday practicality; already the hieroglyphs were so limited in number that they indicate the emergence of a rudimentary but purely syllabic method for the phonetic rendering of proper names. A system of ideograms was restricted to a standard shorthand for objects listed on the tablets, accompanied by numerals and fractions; such ideograms were apparently never confused with syllabic writing. An isolated exception to this ancient practice is found on the so-called Phaistos disk, covered with pictographic clay impressions made from movable types; but it is uncertain that this unique find is truly Cretan, and not an import from Asia Minor.

**Linear A.**—The finds are rather limited in scope and length; both writing and language remain undeciphered. About 1700 B.C. a more advanced cursive system of writing began to displace the hieroglyphs in Crete; in some archaeological strata the two systems are found side by side. The later system, called "Linear A," occurs at many Cretan sites, but the documents are not numerous; they come from Cnossus, Phaistos, Palaikastro, Mallia, Gurnia, Tylissos and elsewhere. The largest find was made at Hagia Triada (well over 150 page-shaped clay tablets and seals), dating from the Late Minoan period (*c.* 1450 B.C.). Despite the spare range of the texts, Linear A tablets appear to record one and the same language (conjectured to be Minoan or Eteo-Cretan), at least to judge from recurring combinations of the same signs in various localities. The comparatively large uniform corpus of Hagia Triada has about 75 syllabic signs, many of which evidently are partly cursive equivalents of related hieroglyphic forms. The narrow oblong tablets necessitated frequent word-division from line to line, and a raised dot was used as a separator between words. The direction of writing, which varied in the hieroglyphs, ran uniformly from left to right. The system of ideograms continued the hieroglyphic tradition, but it also admits the ideographic use of signs otherwise syllabic, probably by way of an acrophonic abbreviation using the initial syllable of corresponding words. Several phonetic signs might be joined into a complex monogram on the same principle, and phonetic ligatures were added to the ideograms proper. The ideograms were followed immediately by signs for numerals and fractions which differ from the corresponding hieroglyphic signs.

**Linear B.**—The Linear B script belonged entirely to the Late Minoan period. Sir Arthur John Evans found over 3,000 tablets or fragments in the latest (i.e., most recent) stratum at Cnossus at the date of its destruction (*c.* 1400 B.C.), but not a single trace of Linear B has been discovered elsewhere in Crete. The script was used primarily on the Greek mainland during the chronologically parallel Late Helladic era. The largest corpus came from the site of Pylos in Messenia, where between 1939 and 1958 Carl Blegen excavated well over 1,000 tablets, many of considerable length and in an excellent state of preservation. Mycenae yielded over 50 tablets during the 1950s. Linear B is found also in inscriptions on jars and pots from Tiryns, Mycenae, Eleusis, Boeotian Orchomenos and, especially, Thebes.

There is no trace of monumental writing anywhere in the Minoan-Mycenaean orbit. Linear B, like its exclusively Cretan predecessor, served mainly for perishable records and inventories of royal palaces and commercial establishments. These temporary clay tablets (some of them of palm leaf shape, with long lines of text) were preserved by being baked in the conflagrations which destroyed the storerooms. Linear B contains 87 different syllabic signs, of which more than half correspond closely in shape to those of Linear A, while one third have no recognizable equivalents. The ideograms and numerals are quite close to the Linear A pattern, but the system of weights and measures contains distinctive signs for fractional quantities, placed after the ideograms but before the numerals; although several signs are obviously related in form to signs for fractions in Linear A, the very system represents a striking departure from the earlier method of reckoning. It might be said that in Linear A the commodities are measured in whole numbers and successively smaller mathematical fractions of an unstated total unit, while the Linear B system measures in terms of smaller conventional units in their own right, which happen also to be fractions of a larger basic unit.

**Decipherment of Linear B.**—One of the great achievements of decipherment in modern times has revealed that Linear B gives the Greek language of the 14th and 13th centuries B.C. The solution advanced in 1953 by Michael Ventris (*q.v.*) was founded on the surmise that the language is early Greek, and that accordingly Cnossus must have been in the hands of Helladic mainlanders before its final destruction about 1400 B.C. In view of the earlier Minoan influence on the mainland, beginning about 1700 B.C., it is uncertain whether Linear B was adapted from the Cretan type by 15th-century Greeks at Cnossus, or was developed on the mainland after Cretan models. The latter is more probable, although the Cnossian corpus antedates all inscriptional evidence from the mainland. The signs generally represent open syllables like *ma*, *mi*, *mo*; such a system may have suited the Minoan language quite admirably, but for Greek it resulted in very awkward rules of orthography, characterized by superfluous vowels and an inability to note certain grouped or final single consonants, or to distinguish between voiceless, voiced and aspirated orders of phonemes. Thus *pa-te* may denote *pater* ("father") or *panter* ("all"); such ambiguity, like the monotonous conciseness of the ledger style and the proliferation of proper names, places limitations on the results to be derived from knowledge of Linear B. Yet the impact of the decipherment has made itself felt in many classical studies.

A distant offshoot of the early Cretan scripts is the undeciphered Cypriote Linear or Cypro-Minoan type, found on a small scale in a number of baked clay tablets from Enkomi in Cyprus and Ugarit in Syria, dated from 1500 to 1100 B.C. A late development of it crops up in the Cypriote syllabary used in Cyprus for writing Greek and Eteo-Cypriote in classical times.

**MINORCA** (Sp. MENORCA), the second in size of the Balearic Islands and a part of Baleares province, Spain, is located 27 mi. N.E. of Majorca. Area 271 sq.mi. Pop. (1960) 42,688. Most of the island is a dry monotonous tableland with an average height between 150 and 300 ft., some rugged hills rising in its north centre to Monte Toro (1,174 ft.). The northern coast is deeply indented with many capes and deep inlets, such as the bays of La Albufera, Addaya and Fornells. The fine natural harbour of Mahón (*q.v.*) is the best port of the Balearics and was much prized for its strategic value in the wars of the 18th century. The south coast is more regular and has long stretches of cliffs. The climate is less equable and rainier than that of Majorca, the island being exposed to cool northerly winds in autumn and winter.

Many of the plateau limestone soils are suitable only for light grazing, but some of the higher districts are terraced and yield rich harvests, as do the few alluvial valleys which run down to the south coast. The *huerta* of Mahón, irrigated by artesian wells, is especially productive, and its windmills are a characteristic feature of the Minorcan landscape. The principal crops are cereals, potatoes, melons, pomegranates, figs and almonds. Cattle, horses, sheep and goats are kept, and cheese is exported to the mainland. The farming system is that of peasant proprietorship, and the domestic economy is supplemented by fishing, lobsters being plentiful off the north coast. The manufacture of leather shoes employs about 10% of the population in a number of small factories throughout the island. Minorca has many beautiful beaches, and its tourist business, formerly much inferior to that of Majorca and Ibiza, is expanding. A road constructed in 1713–15 by Sir Richard Kane, the British governor, connects Mahón (pop. [1960] 16,618 [mun.]), the capital, with Ciudadela (pop. [1960] 12,228 [mun.]), which from Moorish times until the 18th-century British occupation was the capital of Minorca. Air and maritime services link the island with Barcelona and Majorca, and there are air services from London.

Noted for its strong democratic traditions, Minorca remained in loyalist possession for most of the Spanish civil war, 1936–38. For archaeology and history, *see* BALEARIC ISLANDS. (G. J. B.)

**MINORITIES** are groups held together by ties of common descent, language or religious faith and feeling themselves different in these respects from the majority of the inhabitants of a given political entity. On this consciousness of difference the minorities base certain political claims, either for equality with the majority or for special treatment based upon the recognition of these differences, or for autonomy or, in the most extreme cases, separation.

In most cases minorities feel grieved by occupying an underprivileged position. But there are cases when numerical minorities are politically and economically highly privileged like the white population in the Republic of South Africa and when the vast majority of the population feels aggrieved. Thus "majority" and "minority" become primarily political and not numerical concepts.

V. Conclusion

## I. ORIGIN AND NATURE OF MINORITY PROBLEMS

Minorities have always existed, but only after the rise of democracy, in the late 18th century, did they become a serious political problem and play a great role in international relations. Modern humanitarianism and law have tried to dull the sharpness of minority conflicts by providing protection, based upon international treaties, for minorities of race, language or religion.

The origin of some of these minorities can be found not only in past conquests but also in the peaceful unions of different groups. Thus the Muslim minority in India was the result of the conquest of a large part of India by Muslim invaders. Yet this minority, differing in religion and civilization from the Hindu majority, formed itself a majority in vast areas where the Hindus were a minority intermingling with the Muslims. The Russian empire included many minorities as a result of three centuries of widespread conquests in east and west. On the other hand, the Habsburg empire was largely built up by dynastic marriages and succession rights.

Poland contained large and important minorities as a result of a peaceful union between Poland and Lithuania, when the latter included White Russian and Ukrainian populations. Other minorities originated in migratory movements. In former times rulers frequently called colonizers from abroad to settle on wasteland or to introduce new skills and trades. These settlers received special privileges and were allowed to live in closed settlements according to their own rules. Thus important German colonies were scattered in the later middle ages and during the period of the absolute monarchs throughout central and eastern Europe.

Empress Catherine II of Russia settled them in the distant regions on the middle Volga river. In a somewhat similar way European traders settled in oriental communities and were there granted the privileges of extraterritoriality or, as called in the near east, capitulations. Migrations during the Industrial Revolution created minority problems in many parts of Europe and America. Still other minorities (e.g., many religious minorities in the near and middle east) represent the remnants of an older civilization which has resisted the otherwise victorious progress of new religious movements.

Migration also created strongly entrenched Chinese minorities throughout southeast Asia and equally strong East Indian minorities in East Africa and Guiana.

The term minority is flexible in its application with ever fluid limits and perplexing in its political and social consequences. Oppressed minorities often and easily tend to become, at the first opportunity, oppressive majorities, yet as long as they feel themselves underprivileged, they generally appeal to the principles of liberty and humanity and tend to identify their interests with those of the freedom and peace of mankind. They insist upon respect for their own traditions and cultural pattern, irrespective of whether such an insistence forms a bar to greater progress by the preservation of obsolete ways of life.

**1. Religious Minorities.**—Before the beginning of the 19th century, the age of nationalism and democracy, minorities scarcely played any decisive role in national or international politics. Only religious minorities played a distinctive role during the later middle ages and especially in early modern times, when states were often inclined to emphasize their religious homogeneity and therefore tried to eliminate all "heretics." This situation was much aggravated by the Reformation and the ensuing great religious split.

Religious minorities were often treated with great severity and sometimes even forced to emigrate. The great international conflicts of the age were often interpreted as religious wars. Catholic or Protestant princes intervened on behalf of their co-religionists in alien lands. Thus Oliver Cromwell, supported by English public opinion, intervened in 1655 with France for the Vaudois Protestants, a step of which John Morley wrote that "never was the great conception of a powerful state having duties along with interests more magnanimously realized." The treaty of Westphalia, 1648, tried to stabilize the situation, at least in Germany, then the classical land of conflicting religions. It confirmed for the princes of German territories the right of deciding by fiat the religion of their subjects (*cuius regio, illius religio*),

reserving however in such cases the right of emigration for the dissident subjects.

The intervention in favour of religious minorities expressed itself repeatedly in international treaties. In the treaty of Utrecht (1713–14) between Great Britain and France the liberation of the French Protestants in prison for religious causes was stipulated. More frequent were guarantees for the religious liberty of the inhabitants of territories ceded in peace treaties to powers where the majority of the inhabitants, and especially the prince, professed a religion different from that in the ceded territory. In the treaty of Oliva (1660) between Sweden, Poland and Brandenburg, the religious rights of the inhabitants of Livonia, ceded by Poland to Sweden, and of Pomorze, ceded by Brandenburg, were recognized. In the treaties of Nijmegen (1678) Louis XIV of France restored to Holland the town of Maastricht, taken by the French in 1673, reserving religious liberty in favour of the Catholic inhabitants. The same measures of safeguard were inserted in the treaty of Rijswijk (1697). When Prussia acquired under King Frederick II large territories with Catholic population, Silesia from Austria in 1742, and part of western Poland in the first partition of Poland in 1772, the treaties contained provisions in the interest of the new Catholic minorities of Frederick's realm. All these provisions safeguarding religious minorities applied, however, only to limited territories as a result of territorial transfer; they did not include any principle applicable to the states as a whole.

In the 18th century growing religious toleration ushered in an era of equal rights for religious minorities in the British empire and in western Europe. The secularization of the modern state with its separation of state and church brought this process of complete equality in religious matters to its conclusion in the 19th century, except in eastern Europe and in the orient. In the Russian empire the religious minorities remained until 1917 under various restrictions and disabilities as compared with the Orthodox Church. In Iran and other Muslim states Islam remained the dominant and privileged religion. In the Ottoman empire the non-Islamic religions were accorded a large degree of autonomy under their religious heads, and in the 19th century they received gradually equality before the law and citizenship rights. European powers often acted in the 18th and 19th centuries as protectors of their coreligionists in the Ottoman empire, the Russians for the Orthodox minorities, the French and others for the Catholic minorities.

**2. The Age of Nationalism.**—While the victory of religious toleration and liberalism removed gradually the question of religious minorities from the political scene, the growth of nationalism in the 19th century and its penetration to central and eastern Europe and later to Asia created new and ever more disturbing minority problems. The German philosopher and critic of civilization Johann Gottfried von Herder (1744–1803) emphasized the importance of the mother tongue for the cultural life and growth of the individual and his education. Under his influence many of the smaller nationalities in central and eastern Europe found their interest in their own languages and folklore rekindled and began to feel conscious of their position as linguistic and ethnic minorities in the Austrian, Russian and Turkish empires. They began to demand the recognition of their languages in the public administration of their countries; their intellectuals began to elaborate a literature in the native vernacular; and the spread of education in the 19th century carried this insistence upon language and nationality to ever wider circles. This cultural nationalism was strengthened by the message of self-determination carried by the French Revolution and spread over Europe through Napoleon's armies. It undermined the feudal dynastic structure of European society on behalf of the rights of the middle classes and the people. The insistence upon popular sovereignty replaced the supranational prince with a rising class of patriots and the supranational language of court and administration, French or Latin, with the vernacular. Historians and poets recreated a half-legendary past in which the peoples had supposedly played a great part. The dormant national consciousness was thus awakened, and the closer contact created by the Industrial Revolution with its improved communications and the spread of literacy, made the people more conscious of their unity as well as of their difference from groups speaking other languages or living according to different traditional patterns. The 19th century, the age of nationalism, became thus more and more the century of national minority problems. Race, religion and language began to play their roles as characteristics of the national minorities.

In central and eastern Europe, where the political and social developments lagged far behind western Europe, nationalism produced the theory that each nationality should form its own state and that each state should consist of only one nationality. Nationality, recognizable by language, was thus made to coincide, at least ideally, with the state. While the French never put forward the claim of uniting all the French-speaking citizens of Belgium and Switzerland within France nor the Dutch ever demanded the incorporation of the Flemish-speaking Belgians into the Netherlands, the Germans and the Italians directed their political energies to the union of all German- and all Italian-speaking peoples within a united Germany and Italy. Italian-speaking provinces outside the Italian peninsula were regarded as "unredeemed" (*irredenta*) and their movements toward "redemption" by union within a political Italian nation were called "irredentist," a word then applied to other national minority aspirations for separation from the state in which they lived. As far as Italy was concerned, after the unification of the Italian peninsula in the 1860s, the most important centres of irredentism were in Trent in Austrian South Tirol, and in Trieste, the great Austrian port.

While the Italian language minorities lived mostly contiguous with the main territory inhabited by Italian-speaking people, German language minorities were widely dispersed throughout central and eastern Europe, mostly in the midst of Slav populations. These minorities (and later on similar ones in the U.S. and especially in South America) formed the backbone of Pan-German aspirations, which wished to support the expansion of German power and the establishment of German world supremacy by making use of these minorities. In the 20th century Germans and others fostered the national consciousness of their "racial brethren" living "abroad" and tried to forestall the process of their integration with the people in the midst of whom they were living.

On the other hand many Slav people represented minorities in the four great empires of the east, Germany, Austria, Turkey and Russia. The 19th century saw the growth of independence movements among these Slav minorities which often threatened the territorial integrity of the political states in which they lived. Russia, by far the largest Slav nation and in the first half of the 19th century the only independent one, used the Slav aspirations within Austria and Turkey as an instrument of its own power aspirations; Pan-Slavism thus became a vehicle of Russian policy and was especially used to justify Russian interference in Turkish affairs.

The original motive of religious concern for the Greek Orthodox minorities (which in addition to Slav peoples included Greeks and Rumanians) and for the Armenian Orthodox minority was not dropped but fortified through Russia's interest in its "racial brethren," the Serbs and the Bulgarians. Thus minority problems in central and eastern Europe formed in the 19th century one of the most important issues in international relations. They were the cause of the Russo-Turkish wars and of the Balkan wars; they kept alive the tension between Russia and Austria and between Austria and Italy. The fates of the Serbian minority in Austria and of the German minority in Poland were the immediate causes of World Wars I and II.

While the minorities thus played a most important role in international relations, their role in the domestic policies of central and eastern European states was scarcely less important. The revolutions of 1848, often called "the spring of the peoples," awakened the dormant nationalities of central and southeastern Europe to cultural and political consciousness. The revolution of 1905 did the same for the many more backward nationalities

of the vast Russian empire. From 1821, the year of the beginning of the Greek war for independence, until the end of World War I the Turkish empire passed, as a result of minorities' pressure, through a period of progressive territorial disintegration. But it was above all the Habsburg empire which became in the later half of the 19th century the classical land of minority problems and the laboratory for attempts at their solution.

**3. Central Europe.**—The Compromise of 1867 divided the Habsburg empire into a western or Austrian part, and an eastern or Hungarian part. They followed different policies as regards their minorities, though the term "minorities" cannot be applied in either case in the strict sense of the word. Neither in the western nor in the eastern part was there a numerical majority, but in Hungary the Magyars, though numerically a minority, were politically in the position of a dominant majority. The Magyar language was made the only official language, except for the territory of Croatia-Slavonia which enjoyed a measure of autonomy. Government pressure was exercised to assimilate the minorities to the ruling Magyar group whose concern it was to create a purely Magyar state. The Magyars themselves lived in the centre of the country, in the fertile plains of the Danube and Tisza rivers, while around them the minorities—in the north and northwest Slovaks, in the northeast Ukrainians, in the east (Transylvania) Rumanians and in the south Croatians and Serbs—lived in compact groups. Yet even within these compact minority settlements, there were other minorities interspersed. Thus in Transylvania, among a large Rumanian majority, a Magyar minority, the so-called Szeklers, lived in the eastern part of the land, separated from the majority settlement of the Magyars, while in the south there was a German minority, the so-called Saxons. An even greater mixture of minorities was presented by the Banat in southeastern Hungary, where Magyars, Serbs, Rumanians, Germans and others intermingled, while German minorities, mostly called Swabians, were numerous in many parts of Hungary, especially in the south and the centre.

The non-Magyar minorities resented being treated as subject races to an ever growing degree, especially because some of them like the Rumanians, the Serbs, the Slovaks and the Ukrainians were living in direct contact with kindred peoples beyond the frontiers of Hungary, a fact which increased the centrifugal tendencies and prepared for the disintegration of Hungary in 1918.

Similar centrifugal tendencies threatened the existence of Austria, though in its case one cannot speak of any real oppression of the minorities. Article 19 of the constitutional law of Dec. 21, 1867, provided for the equality of the different nationalities ("all nationalities in the state have equal rights") and proclaimed that every nationality had an inviolable right to preserve and promote its national character and language. Austria recognized in its fundamental laws the equality of all usually spoken languages in education, in the administration and in public life. These provisions were by far the most liberal and progressive of the period, but they were vague, and the following half century was largely filled with a conflict for the interpretation of this fundamental act, the Magna Carta of the Austrian nationalities. Fierce national struggles centred around the rights and usages of the different languages and around changes in the economic position of the different nationalities. These struggles often impeded the functioning of the Austrian parliament. Many interesting and promising attempts to solve the minority problem were made, especially in the provinces of Moravia and Bukovina, but on the whole the problem remained unsolved in Austria until under the stress of World War I the state disintegrated and its minority problems were inherited by the so-called succession states.

Of the different provinces of Austria few were inhabited by only one nationality; most of them had their minority problems. In Bohemia, Moravia and Silesia there were Czechs and Germans, in the latter also Poles. In Styria and Carinthia Germans and Slovenes lived side by side; in the territories along the Adriatic coast Italians and Slovenes mingled in the north, Croats and Italians in the south. Southern Tirol had an Italian minority. In the Bukovina Ukrainians, Rumanians and Germans lived interspersed, while in Galicia the western part was predominantly Polish and the eastern part, except for the upper classes in the cities, largely Ukrainian. Many of these minorities were supported by kindred people speaking the same language on the other side of the frontiers. Thus the Austrian-Italian minority looked to Italy for guidance, some of the Croats and Serbs, especially after Austria's annexation of Bosnia-Hercegovina (1908) with its large Serbo-Croat population, saw in the independent Serbian kingdom in the Balkans the centre for the unification of all the southern Slavs, many of the Austrian Germans longed for inclusion in the German *Reich* created by Bismarck. This Pan-German movement was especially strong in the German-speaking parts of Bohemia, later called the Sudetenland, where Georg von Schönerer started a violently anti-Habsburg, anti-Catholic and anti-Semitic movement, a tradition in which Adolf Hitler later grew up. The Poles in Galicia had no independent nation outside the Austrian borders with which to be unified, but throughout the 19th century they hoped for the restitution of a united Poland, made up of the Russian, Prussian and Austrian parts of the former Polish state.

Of the three groups into which Poland had been divided, the Poles in Austria were by far the best treated; they were the only ones to enjoy full political and cultural liberties, and even occupied in Austria a privileged position and developed a class of high civil servants and well-trained administrators. Some Czechs and the Slovaks, living entirely on Austro-Hungarian territory, looked expectantly to Russia, the big Slav brother, for help in their national liberation. With all these mingled populations and conflicting aspirations, the dissolution of the Habsburg empire at the end of World War I presented a difficult problem for the new ordering of Europe, especially as the victors of World War I emphasized the principle of national self-determination and the liberation of minorities.

Infinitely simpler than in Austria were the minority problems within the German empire. There the minorities lived along the borders of the empire in compact groups contiguous with kindred populations beyond the frontiers, and had been incorporated into the German political system only in relatively recent times as a result of territorial aggrandizement and victorious wars. The Poles, mainly in the provinces of Poznania and western Prussia, had come under Prussian domination as a result of the partitions of Poland in the 18th century; the Danes in northern Schleswig were included in Prussia as a result of the Seven Weeks' War of 1866, and finally Alsatians and Lorrainers had been forced against their will into the new German empire after the German victory over France in 1871. All these minorities felt bitterly oppressed within the German empire; its defeat in 1918 offered the opportunity for the liberation of these minorities and their reunion with their Polish, Danish and French conationals. Especially the Polish minority had been subjected to a process of forced denationalization, and drastic methods had been adopted in the "eastern marches" to dispossess the Poles and to settle Germans in their stead.

As a result of this German settlement policy and of the germanization of some of the cities within Polish territory, the drawing of the frontier between Germany and Poland presented some difficulty in 1918. In addition to these three more recent minorities, who were backed by their conationals outside Germany, the German empire included some submerged Slav minorities like the Sorbs or Wends in Upper Lusatia and the Masurians of eastern Prussia.

**4. The Russian Empire.**—In the Russian empire, which had grown rapidly through the conquest of vast territories from the 16th to the 19th centuries, the Russians themselves formed barely a majority of the population. The country was inhabited by almost 100 different nationalities, some of them numerically insignificant, others very sizable, some of a higher cultural level than the Russians themselves, many others in different stages of backwardness, in their totality representing an infinite variety of races, European and Asiatic, and of religions, Catholic and Protestant, Muslim and Buddhist. The highly cultured minorities living on the western fringes of the empire, like the Germans in

the Baltic provinces, the Poles and the Finns, enjoyed in the first half of the 19th century varying but on the whole far-reaching degrees of autonomy. In the later part of the century, however, the empire followed increasingly a determined policy of russianization of all the minorities, reserving for the Russian nationality and for the Greek Orthodox Church a position of privilege while oppressing the minority nationalities and religions. This oppression took different forms, but the denial of equality and of political rights was common to all of them. The Jews formed the most oppressed minority. The revolution of 1905 marked the first step in easing the situation of the minorities; the democratic March revolution of 1917 brought the proclamation of their complete equality.

The highly developed border nationalities in the west, the Poles, Lithuanians, Latvians, Estonians and Finns, proclaimed their independence which the new Soviet government was then too weak to deny; the rest of the empire was reconstituted as the Union of Soviet Socialist Republics, which granted equality to all its minorities and, at least theoretically, abolished the privileged position of the Russian element. The unexpected simultaneous disintegration of Austria, Germany and Russia made possible the reconstitution of a unified Poland.

Similarly complex as in the Habsburg and Russian empires was the minority situation in the Ottoman empire in the 19th century. In its European part many minorities, the Greeks, the Rumanians, the Serbs, the Bulgarians and finally the Albanians, achieved their independence, but the intermingling of minorities left many problems unsolved, especially in Macedonia, which was claimed by Greece, Serbia and Bulgaria, and in Albania where in the north Serbs and in the south Greeks lived on territory claimed as Albanian. Asiatic Turkey with its Greek and Armenian minorities among the Christians, Arab and Kurdish minorities among the Muslims, presented a complex problem at the end of World War I which under the then existing circumstances was solved in different ways, by separation (Arabs), by suppression (Armenians and Kurds) and finally by exchange of populations (Greeks).

**5. Western Europe.**—Fundamentally different from the situation in central and eastern Europe was the problem in western Europe. If we regard as a minority in the technical sense here discussed "a group that does not feel at home" in the state where it lives (Edgar J. Fisher), neither the Scots nor Welsh in Great Britain nor the Bretons nor Basques in France nor the Italians in Switzerland can be regarded as minorities. Before World War I there were only two true minorities in western Europe: the Catalans and to a lesser degree the Basques in Spain, and the Irish in Great Britain since the union. The Catalans, culturally and economically more advanced than the Spaniards, demanded cultural and political autonomy and opposed the centralizing tendencies of the Madrid government which went so far as to suppress the use of the Catalan language. The Irish minority problem was on the way to solution before World War I by Great Britain's readiness to grant Ireland home rule. Efforts in that direction, started when William E. Gladstone's third ministry in 1886 introduced the first Home Rule bill, were crowned by the passage of the (third) Home Rule bill in Sept. 1914, but the Irish situation was complicated by a typical minority problem, the Scottish Protestant minority in northeastern Ireland (Ulster), which appealed to its own right for self-determination against its subjection to Irish Catholic majority rule. A further complication was presented by a large Irish Catholic minority within Ulster, the territory of the Irish Protestants. As in many other cases (Catholic Poles and Protestant Prussians, Catholic Poles and Orthodox Ukrainians, etc.), the national minority problem was aggravated by religious differences, though many of the leaders of the Irish Catholics in their struggle against England were Protestants of English descent.

## II. WORLD WAR I AND ITS AFTERMATH

That was the complex minority situation found at the beginning of World War I, a war which from its start involved the rights of small nationalities (Serbia and Belgium). As early as Aug. 5, 1914, the British prime minister, Herbert Asquith, declared that "We are fighting . . . that small nationalities are not to be crushed, in defiance of international good faith, by the arbitrary will of a strong and overmastering power." From the beginning of the war Germany appealed to the minorities within the Allied nations (the Irish in Great Britain, the Poles and others in Russia) and tried to enlist them in the service of the German cause. Similarly the Muslim Turks tried to enlist the Muslim subjects of Great Britain, Russia and France in a "holy war" on the side of Germany and Turkey. Later on the Allies appealed to the minorities in Austria-Hungary, in Turkey and in Germany and tried to win them for collaboration with the Allies for the realization of what soon became one of their declared war aims, the recognition of the principle of nationality and self-determination. The British entered into negotiations with the Arabs and succeeded in enlisting Sherif Husain ibn Ali of Mecca, to raise the banner of Arab independence and unity in 1916. The Russians, followed by other Allied nations and the United States, held out the prospect of autonomy or independence for the Armenians in Turkey. Leaders of the various non-Germanic and non-Magyar peoples of the Habsburg monarchy entered into negotiations with Allied and U.S. statesmen.

The principles of nationality and self-determination were accepted as an official war aim by President Wilson in his address to congress, Jan. 5, 1918, when he demanded in point 9 "a readjustment of the frontiers of Italy along clearly recognized lines of nationality"; in point 10 that "the peoples of Austria-Hungary should be accorded the freest opportunity of autonomous development", in point 11 the adjustment of Balkan relations along historically established lines of nationality; in point 12 "an absolutely unmolested opportunity of autonomous development" for the minorities in Turkey; and in point 13 the erection of an independent Polish state to include the territories inhabited by indisputably Polish populations and assured a free and secure access to the sea. In his address to congress Feb. 11, 1918, the president repeated that "All well-defined national aspirations shall be accorded the utmost satisfaction," but he introduced also the warning and restricting qualification "that can be accorded them without introducing new or perpetuating old elements of discord and antagonism that would be likely in time to break the peace in Europe and consequently of the world." Wilson's 14 and supplementary points were unfortunately as vague as regards national self-determination as in most other respects, proclaiming general principles rather than the clear bases of a policy to be followed.

**1. Peace Treaties of 1919.**—The peace treaties of 1919 created east of the Rhine and the Alps a new Europe. The intention was to bring central and eastern Europe into line with the progressive development of western Europe and to introduce there the principles of constitutional liberty and of the nation-state based upon self-determination. In reality, the new Europe was not shaped exclusively or even predominantly by the good intentions of the peace treaties but by events which preceded the deliberations and decisions of the peace conference—such as the revolution and disintegration in Russia and the dissolution of the Habsburg empire—and by events following the peace treaties and settling international disputes without reference to the peace treaties (the Russo-Polish campaign of 1920, the seizure of Vilnius and Memel, the events in Turkey, etc.). The intention of creating the new Europe of individual and national liberty could not be fully realized, too many conflicts of the past, some of them reaching back for centuries, continued to influence the political life of Europe and to arouse the emotions of the masses. But even within the narrow limits in which the new Europe was ordered by the peace treaties themselves, the complete realization of the principle of national self-determination was found impossible. Minorities continued to exist and to present serious problems for international relations and domestic policies alike.

Had the principle of self-determination been carried out with complete disregard of all considerations of strategy and welfare, there would have remained important minorities in central and eastern Europe as a result of the intermingling of populations.

Many minorities lived separated from their conationals, so that it would have been entirely impossible to include them in states with a predominant population of their own nationality. The partition of Austria-Hungary and the realization of the principle of national self-determination along the western borders of the Russian empire created a situation which had to a certain degree to continue the many centuries old cohabitation of minorities of race, language and religion. One of these minorities, the Jews, who in eastern Europe had not undergone the process of assimilation which integrated them into the western nations, but had preserved in their mass settlements their own language and civilization, lived dispersed over several of the eastern European states and thus represented—at least until the time when progressive assimilation would possibly change the situation—a permanent minority. The newly created or enlarged states, Czechoslovakia, Poland, Rumania and Yugoslavia, resembled the Habsburg monarchy by the composite character of their populations. But on the whole the peace settlements of 1919 created a map of Europe much more in accordance with the principle of national self-determination than the map of 1914 had been. While in 1914 about 100,000,000 persons did not "feel at home" in the states in which they lived, their number was reduced as the result of World War I to about 25,000,000.

But in their effort to promote the growth of liberty and equality the peacemakers of 1919 did not stop at redrawing the map of Europe. They developed a system of protection by international treaties for minorities of race, language or religion. Such protection by international treaty had already been applied on a very limited scale in the 19th century, without however any supervision by an international body. In the case of the new Balkan states the protection of religious minorities and their rights was made a condition for the recognition of the new states. The treaty of Berlin (1878) stipulated in article 44 that differences of religion should not cause any differences in civic and political rights. The treaty of Berlin sought to guarantee, above all, the civic and political rights for the Jewish inhabitants of Rumania, which had refused to recognize them as citizens. But even after 1878 Rumania deliberately refused for 40 years to naturalize its Jewish inhabitants and to treat them as citizens. In view of this experience and of the violent anti-Semitism prevailing in Rumania and in the western part of the Russian empire (Poland and Ukraine), the Committee of Jewish Delegations at the Peace conference in Paris petitioned the peace conference on May 10, 1919, to secure to the people of the newly created or enlarged states of Europe, with adequate constitutional guarantees under the sanction of the League of Nations, admission to citizenship, civil, religious and political liberties as individuals and the right of organization and development as national minorities.

**2. Europe After 1919.**—No provisions for the protection of national, religious and racial minorities were incorporated into the text of the covenant of the League of Nations, though the Japanese delegation pressed for such a provision. But at the eighth plenary session of the peace conference on May 31, 1919, the French prime minister Georges Clemenceau and President Wilson emphasized the need for special protection for minorities in certain states. As a result of all the preceding deliberations and negotiations a treaty was signed between the principal Allied and associated powers on the one hand, and Poland on the other, at Versailles on June 28, 1919, the same day when the treaty with Germany was signed. The treaty with Poland served as a model for similar minority treaties concluded with other nations. In the treaty, Poland, "desiring to conform her institutions to the principles of liberty and justice, and to give a sure guarantee to the inhabitants of the territory over which she has assumed sovereignty," undertook to assure full and complete protection of life and liberty to all inhabitants of Poland without distinction of birth, nationality, language, race or religion. All inhabitants of Poland were to enjoy religious freedom, persons residing in Polish territory at the time of the treaty were to become, if they so desired, Polish citizens, and all Polish citizens should enjoy the same civil and political rights. In addition to these general provisions characteristic of any progressive or democratic country, there were special provisions about the right of the free use of non-Polish languages in private intercourse and in publications and about adequate facilities for the use of these languages before the courts. Minorities received the right to establish at their own expense social and educational institutions, and Poland promised to provide adequate facilities to the minorities for education in elementary schools through the medium of their own language. Finally Poland agreed that these obligations should be placed under the guarantee of the League of Nations, and that any member of the council of the League should have the right to draw the attention of the council to any infraction, or any danger of infraction, of any of these obligations, whereupon the council might take proper and effective action. Poland also agreed that the minority protection could not be modified without the assent of the majority of the council of the League of Nations. Any difference of opinion as to the minority treaty should be held to be a dispute of an international character under article 14 of the League covenant and should, if the other party so demanded, be referred to the Permanent Court of International Justice.

Minority treaties were concluded only with a number of newly formed and enlarged states; similar provisions were inserted in the peace treaties with certain defeated states; and finally some new states, at the time of their admission to the League of Nations, accepted in solemn declarations the principles of the minority treaties. The states thus entering into international obligations for the protection of minorities formed finally a belt from the Finnish gulf in the north to the Persian gulf in the south. Minority treaties were signed, in addition to Poland, by Yugoslavia (Sept. 10, 1919), Czechoslovakia (Sept. 10, 1919), Rumania (Dec. 9, 1919) and Greece (Aug. 10, 1920). In the peace treaties with Austria, Bulgaria, Hungary and Turkey special chapters for the protection of minorities were inserted. In addition the following states when admitted to the League of Nations made declarations regarding minorities before the council of the League: Finland (in respect of the Åland Islands), June 27, 1921; Albania, Oct. 2, 1921; Lithuania, May 12, 1922; Latvia, July 7, 1923; Estonia, Sept. 17, 1923; Iraq, July 13, 1932.

In addition to these treaties and declarations, minority questions were also dealt with in a number of bilateral international agreements. The most important among these agreements were the German-Polish convention regarding the protection of minorities in Upper Silesia of May 15, 1922, and the Greco-Turkish agreement on the compulsory exchange of minority populations of Jan. 30, 1923. The convention regarding the Memel territory of Lithuania on May 8, 1924, also dealt with minority problems.

The international protection of minorities was not extended to old established states, not even to defeated Germany. As a result of World War I Italy incorporated into its national territory certain parts of the former Austro-Hungarian empire which were inhabited by Italians, South Tirol, Trieste and the Austrian maritime provinces, the main centres of the Italian irredentism of the 19th century. But while point 9 of Woodrow Wilson's 14 points had demanded the readjustment of the Italian frontiers along clearly recognizable lines of nationality, the new frontiers granted Italy by the peace treaty included large minorities, German in the case of South Tirol, Slovene and Croat in the case of Trieste and the maritime provinces. These minorities were not only not protected by any minority treaty, but were soon subjected by the fascist regime in Italy to an especially ferocious process of denationalization and persecution.

World War I did not create any new minority problems in western or northern Europe. One of the thorniest existing minority problems, the Irish problem, was solved by the treaty which the British government signed on Dec. 6, 1921, with the Irish representatives and which was accepted by *dail eireann* the following month. The Protestant minority in Northern Ireland received home rule under the Government of Ireland act of Dec. 23, 1920, and retained this position in agreement with the right of self-determination even after the rest of Ireland had been granted one year later dominion status as the Irish Free State. The large Catholic minority in Northern Ireland continued however to pre-

sent a minority problem, especially in view of the strong support which it found in the Free State.

In Spain the Catalans demanded with ever-growing insistence the autonomy of Catalonia. On July 5, 1917, the Catalan deputies and senators in the Spanish parliament asked the convocation of a Catalonian constituent assembly to draw up a constitution for Catalonia, and on Jan. 24, 1919, a Catalonian union met in the Catalonian capital, Barcelona, to draft a program for home rule. The Spanish dictatorship of Gen. Miguel Primo de Rivera (1923–30) rejected all these demands, but the Spanish republic granted limited local autonomy to Catalonia in its constitution of Dec. 9, 1931. Catalonian agitation resulted in a far more liberal and comprehensive measure in the Catalan charter of autonomy of Sept. 25, 1932, in which Catalonia was granted the right to its own flag and official language and its own president, parliament and cabinet. The Basques received a more limited autonomy on Oct. 5, 1936. But the victory of Gen. Francisco Franco's forces in the Spanish civil war and the establishment of a fascist nationalist dictatorship in 1939 led to the abolition of autonomy in Catalonia and in the Basque provinces and to a regime of persecution of the minorities, of their languages and cultural aspirations.

**3. Soviet Russia.**—The minority problem in the vast Russian empire remained of importance even after World War I. Movements for national independence on the part of the larger and more developed national minorities, the Ukrainians, the Caucasians and the Muslims in central Asia, were ruthlessly suppressed, the potential leaders of such national independence movements were executed or imprisoned, and the totalitarian direction of all life and all administration by the one strictly centralized Communist party throughout the empire provided an iron framework of uniformity. But within this framework the minorities of race and language at first received a formerly unknown legal equality, and the minority religions—Muslim, Jewish, Buddhist, Catholic, Protestant—were held to be on a footing of equality with the Orthodox Church. The Russian empire, though maintaining in its main body its unity and even strengthening the hold of Moscow over the vast extent of the empire, was transformed in 1922 into the Union of Soviet Socialist Republics, in which the European and Asian peoples were organized in federal republics, originally 7, 11 in 1939 and 16 in the early 1950s.

According to the census of 1926 the Union of Soviet Socialist Republics was inhabited by 185 peoples, speaking 147 different languages. Of these nationalities the Russians formed a bare majority of 52.9% (in 1939 the figure was 58.2%). Many of these nationalities were small groups, numbering less than 100,000; only 13 comprised more than 1,000,000 each. While some of these nationalities formed the republics of the Soviet Union, many more of them formed autonomous districts within one or the other of the republics. The largest of these republics, the Russian Soviet Federated Socialist Republic or R.S.F.S.R., which in the census of Jan. 1960 accounted for 117,494,000 out of a total population of 208,826,650 for the Soviet Union, dwarfed, however, all the other national republics in space and importance. Thus the U.S.S.R. remained predominantly Russian.

The practical policy of the Soviet government promoted actively and consistently the fullest development of the languages spoken by the minorities. The fight against illiteracy, the introduction of compulsory education, the spread of socialistic and popular scientific literature among the masses, the new equality of women, all this was accomplished through the medium of the mother tongue of each nationality or minority. While thus linguistic autonomy was granted, and no legal distinction was made between the Russian majority and the minorities in their rights and status, neither cultural autonomy nor political liberty in the accepted sense of the word existed, because the cultural and political life of all inhabitants, irrespective of race, nationality or language, was uniformly molded in the pattern of the totalitarian dictatorship.

The success of the Soviet minorities policy was tested in World War II. It became clear that many non-Russian nationalities were not loyal to the Soviet government, which in their eyes represented Russian domination. With the German attack in 1941 the Soviet government found itself obliged to dissolve the autonomous soviet socialist republic of the Volga Germans which it had established in 1924. Its German inhabitants were moved to Siberia and their autonomy liquidated. The capital of the republic regained its former Russian name, Pokrovsk (renamed Engels [q.v.] after 1931). At the end of World War II it became known, without any previous announcement by the Soviet government and without any explanation, that four other former autonomous republics and regions had been liquidated, the Crimean (Tatar) A.S.S.R., the Kalmyk A.S.S.R. west of the lower Volga, the Chechen-Ingush A.S.S.R. and the Karachai-Cherkess Autonomous Region in the Caucasus. Their cities were deprived of their native names and received Russian names. What happened to the populations was not revealed. The reason for these measures was believed to be the disloyalty of these minorities during World War II.

In a special report to the 20th congress of the Communist party of the Soviet Union, Nikita S. Khrushchev, the first secretary of the party, on Feb. 24, 1956, included the treatment of these minorities among the crimes of the Stalin era. He called the mass deportations from their native places of whole nations, together with all their Communists and Komsomols without any exception, a monstrous act. He revealed a fact unknown until then when he said that "the Ukrainians avoided meeting this fate only because there were too many of them and there was no place to which to deport them. Otherwise, Stalin would have deported them also." Khrushchev continued that "no man of common sense can grasp how it is possible to make whole nations responsible for inimical activities, including women, children, old people, Communists and Komsomols, to use mass repression against them, and to export them to misery and suffering for the hostile acts of individual persons or groups of persons."

After 1956 steps were taken by the Soviet government to restore some of the autonomous republics and regions abolished during World War II and to bring the populations back to their native places. Two of the autonomous republics liquidated during the war on Stalin's orders were not mentioned by Khrushchev and were not re-established, the Volga German and the Crimean Tatar republics. Apparently their populations remained in Siberia and Kazakh, distant regions to which they had been deported.

During the last 15 years of Stalin's rule the position of the minorities throughout the U.S.S.R. had rapidly deteriorated compared with the relative equality granted them under Lenin. Under Stalin's successors greater emphasis was placed again upon the theoretical recognition of equality and the cultural development of the non-Russian nationalities in the U.S.S.R. The only exception were the Jews who, under Khrushchev too, were denied freedom of cultural activity in their own language (Yiddish).

**4. Central and Eastern Europe.**—Different from these developments in western and eastern Europe was the evolution of minority rights in the 14 states in central-eastern and southeastern Europe which had accepted, by treaty or solemn declaration, the protection of minorities within their territories. It was with these states and their minority problems that the League of Nations dealt in the period between World Wars I and II. These states were the following:

Albania, with a population of 1,003,000 (1930), of whom 50,000 belonged to the Greek and 7,000 to the Yugoslav minority.

Austria, pop. 6,760,000 (1934), of whom 52,000 were Czechoslovaks, 25,000 Hungarians, 191,000 Jews and 85,000 Yugoslavs.

Bulgaria, pop. 5,478,000 (1926), of whom 27,000 were Armenians, 11,000 Greeks, 47,000 Jews, 61,000 Rumanians and 578,000 Turks.

Czechoslovakia, pop. 14,729,000 (1930), of whom 3,318,000 were Germans, 715,000 Hungarians, 357,000 Jews, 81,000 Poles and 560,000 Ukrainians.

Estonia, pop. 1,126,000 (1931), of whom 16,000 were Germans, 4,000 Jews, 7,000 Letts and 92,000 Russians.

Greece, pop. 6,205,000 (1928), of whom 20,000 were Albanians, 35,000 Armenians, 82,000 Bulgarians, 70,000 Jews and 103,000 Turks.

Hungary, pop. 8,684,000 (1931), of whom 103,000 were Czechoslovaks, 476,000 Germans, 444,000 Jews, 16,000 Rumanians and 34,000 Yugoslavs.

Iraq, pop. 3,185,000 (est. 1935), of whom 45,000 were Assyrians, 89,000 Jews, 485,000 Kurds and 80,000 Turks.

Latvia, pop. 1,900,000 (1930), of whom 8,000 were Estonians, 62,000 Germans, 93,000 Jews, 20,000 Lithuanians, 50,000 Poles, 233,000 Russians and 36,000 White Russians.

Lithuania, pop. 2,220,000 (1931), of whom 71,000 were Germans, 166,000 Jews, 14,000 Letts, 73,000 Poles and 44,000 Russians.

Poland, pop. 32,694,000 (1931), of whom 30,000 were Czechoslovaks, 1,700,000 Germans, 2,700,000 Jews, 300,000 Lithuanians, 56,000 Russians, 4,200,000 Ukrainians and 1,500,000 White Russians.

Rumania, pop. 17,793,000 (1930), of whom 361,000 were Bulgarians, 740,000 Germans, 1,426,000 Hungarians, 725,000 Jews, 415,000 Russians, 578,000 Ukrainians and 289,000 Turks.

Turkey, pop. 13,629,000 (1927), of whom 134,000 were Arabs, 64,000 Armenians, 96,000 Circassians, 120,000 Greeks, 82,000 Jews and 1,184,000 Kurds.

Yugoslavia, pop. 13,934,000 (1931), of whom 342,000 were Albanians, 176,000 Czechoslovaks, 499,000 Germans, 468,000 Hungarians, 77,000 Jews, 229,000 Rumanians and 132,000 Turks.

Thus the most important minorities in the 14 minority states were 6,885,000 Germans (mostly in Czechoslovakia, Poland, Rumania, Yugoslavia and Hungary), 2,638,000 Hungarians or Magyars (in Rumania, Czechoslovakia and Yugoslavia), 5,045,000 Jews (mostly in Poland, Rumania, Hungary and Czechoslovakia), 1,669,000 Kurds (in Turkey and Iraq), 5,347,000 Ukrainians (in Poland, Rumania and Czechoslovakia) and 1,536,000 White Russians (in Poland and Latvia).

Of these minorities the Germans and Hungarians (Magyars) presented internationally the greatest problem. They had formerly belonged to the ruling majorities in Germany and in Austria-Hungary, and their new position was a result of the defeat of the Central Powers in 1918. Both in Germany and in Hungary tendencies were dominant, from 1918 on, to undo the defeat of 1918 and to re-establish the former German and Hungarian hegemony in central Europe. German and Hungarian policy was dominated by the goal of revising the peace treaties, and with them the new minority situation in central Europe.

Different was the problem presented by the Ukrainian, Jewish and Kurdish minorities. The Ukrainians, a nation of about 40,000,000 people, found after 1918 their claim to national independence denied and the territory settled by them divided among the Soviet Union, Poland, Czechoslovakia and Rumania, the Ukrainians forming everywhere a minority. In the Soviet Union the Ukrainians, forming the second largest national group, were organized into one of the federated republics according to the Soviet pattern. Czechoslovakia promised in the minority treaty to grant to the Ukrainians, living on the eastern fringe of Czechoslovakia south of the Carpathian mountains, the fullest degree of self-government compatible with the unity of the state. This autonomy was very gradually realized and finally established only in 1938, shortly before the complete dismemberment of Czechoslovakia. A similar autonomy was promised by the Polish government to the Ukrainians in eastern Galicia, a province consisting of the three districts of Lvov, Stanislawow and Tarnopol. The Polish law of Sept. 26, 1922, provided for diets in these districts to deal with all questions relating to religion, education, welfare, local communications and local economic conditions. The law also prohibited the Polish colonizing of these districts, made the Ukrainian language one of the two official languages, and promised the establishment of a Ukrainian university. On the strength of this law the Conference of Ambassadors recognized on March 14, 1923, the Polish claims to eastern Galicia, not without pointing out that Poland had recognized for eastern Galicia "that the ethnographical conditions made a regime of autonomy necessary." After 25 years a plebiscite should decide, according to the Conference of Ambassadors, the status of eastern Galicia. But the Polish government refused to carry out the law of Sept. 26, 1922, and the 3,500,000 Ukrainians in eastern Galicia remained without the promised autonomy. After 1940 the Soviet Union, by the annexation of Bessarabia and northern Bukovina from Rumania and of eastern Galicia, Volhynia and Polesie from Poland, united all the Ukrainians, with the exception of those in Czechoslovakia, within the Soviet Union and its Ukrainian republic. In 1945 the Carpatho-Ukraine was ceded by Czechoslovakia to Russia, thus completing the process of the inclusion of all Ukrainians, for the first time in history, into the Soviet empire.

The Jews formed a minority in all the states involved. Special provisions were made in the treaties with Poland, Lithuania and Greece in the interests of the observance of the Jewish Sabbath. No elections should be held on Saturday. This provision did not, however, exempt Jews from such obligations as were imposed on all other nationals for the necessary purposes of military service, national defense or the preservation of public order. Similar regard for religious minorities was expressed in the treaties with Albania, Greece and Yugoslavia as far as Muslims were concerned. Greece also promised to maintain the traditional rights and liberties enjoyed by the monks of Mt. Athos, of whatever country they might be natives.

Like the Ukrainians, the Kurds formed no national state of their own but lived as minorities in Turkey, Iran and Iraq. There was no question of protection for minorities in Iran. Turkey assumed certain obligations, but it did not grant any minority rights to the Kurds nor did it make any provisions for the use of the Kurdish language in education or public life, though the Kurds formed a considerable minority living in compact settlements in the eastern parts of the country. The treaty of Sèvres (1920) had foreseen autonomy for the Kurds, but it was never ratified. The Turkish government suppressed movements for independence or autonomy on the part of the Kurds and subjected them to a process of turkification. Only in Iraq the Kurdish minority in the northern districts enjoyed full minority rights and a limited cultural and administrative autonomy.

More extended and better defined than in any other of the minority treaties were the rights of the German and Polish minorities in Upper Silesia as set forth in part iii of the German-Polish convention of May 15, 1922. The contracting parties agreed to observe, for a period of 15 years, certain detailed provisions concerning civil and political rights, religion, private education, public elementary education, vocational training and extension classes, secondary and higher education, the official language of education and the language to be employed in all legal proceedings of whatever nature. In both parts of Upper Silesia, German and Polish, a minorities office was set up to which persons belonging to a minority could, after having filed a complaint with the highest administrative authority of their territory, submit a petition for consideration. If the minorities office did not succeed in obtaining satisfaction for the petitioners, it transmitted the petition, with any comments of its own, to the president of a mixed commission. This commission was composed of two Germans and two Poles with a president of a third nationality. This commission communicated its views to the proper administrative authorities. If the petitioners were not satisfied with the findings of the administrative authority, they could appeal to the council of the League of Nations. This convention remained in force for the full duration contemplated in it and ended on May 15, 1937.

**5. Protection by League of Nations.**—Thus in the new system established by the peace treaties after World War I minorities of race, religion or language were to receive for the first time protection under an effective system of international law. Though, as in all the other provisions of the peace treaties, much remained vague and undefined and lacked sanction, nevertheless the arrangement marked important progress in a most delicate question, namely, how far effective protection of minorities could be achieved internationally without seriously impairing the national sovereignty of the states themselves. A principle, experienced by the assembly of the League of Nations in 1922, interrelated the duties of the state toward its minorities with the duties of the minorities toward the state. While the assembly recognized the primary right of minorities to be protected by the League from oppression, it also emphasized the duty incumbent upon persons belonging to racial, religious or linguistic minorities to co-operate as loyal fellow citizens with the nations to which they belonged.

In that connection nothing could be more disastrous than an appeal of the minority to some protecting outside government, especially a great power. Such appeals had been used successfully in the 19th century by minorities in the Ottoman empire, and this kind of protection of minorities by the intervention of some great powers had produced disastrous results by complicating international relations and provoking wars. The new procedure of protecting minority rights under the League of Nations should render, so the framers of the peace treaties had intended, such

appeals of minorities to single powers superfluous. The necessity of striking a delicate balance between the sovereign rights of states and the protection of minorities within those states was always taken into consideration by the League of Nations which tried to achieve its aims by conciliation and pacification rather than by judgment and sanctions. The resolution of the assembly in 1922 stated in this spirit that:

While in cases of grave infraction of the minorities treaties it is necessary that the Council should retain its full power of direct action, the Assembly recognizes that in ordinary circumstances the League can best promote good relations between the various signatory governments and persons belonging to racial, religious or linguistic minorities placed under their sovereignty by benevolent and informal communications with those governments.

In the course of the years the League of Nations worked out a procedure to be followed by the council in the settlement of minority questions. The minority treaties were extremely general in their wordings and vague about the procedure and the powers of the council. Only members of the council had the right to bring officially to the attention of the council any infraction or danger of infraction of any of the provisions relating to minorities. Other states not represented on the council, or minorities themselves, could petition the council or report to it, but only an action by a council member brought the question officially before the council. When the council dealt with such a question, the state involved, if it was not a member of the council, was invited to sit as a member during the consideration of the matter specially affecting its interests. The council could also ask the Permanent Court of International Justice for an advisory opinion or refer the question to it.

The procedure laid down by the council concerned petitions and communications for the examination of minority questions not sponsored by any of the members of the council. The council, anxious to give minorities a guarantee that their petitions would receive serious consideration, instituted out of its midst a minorities committee. A petition regarding minority protection was first submitted by the League secretariat to a preliminary examination as regarded its acceptability; if found acceptable, it was submitted to the government in question for its own observations, before being brought to the notice of the council. The observations of the government, if any, were communicated together with the petition. The council became competent to deal with the question, however, only if one of its members notified it that the subject of the petition constituted an infraction or danger of infraction of the treaties. To enable its members to decide whether the petition constituted such an infraction, the council instituted the minorities committee, consisting of the president of the council and two members appointed by him. According to a resolution of the council of June 10, 1925, the members of the minorities committee could not include either the representative of the state to which the persons belonging to the minority in question were subject, nor the representative of a neighbouring state or of a state a majority of whose population belonged from the ethnical point of view to the same people as the persons who were members of the minority in question. In such a way the impartiality of the minorities committee was to be assured. As a result, nationals of Latin-American or Asian states played a great role in these minorities committees.

This procedure was further improved by the resolution of the council of June 13, 1929. The secretary-general of the League was required to inform the petitioner when and why his petition was unacceptable. In exceptional cases the minorities committee could be expanded from three to five persons. It was declared desirable that these minorities committees hold their meetings not only during the sessions of the council but also in the intervals between them. The committees had to inform all the members of the council of the result of their findings regarding minority petitions, so that members who were not in agreement with the findings could raise the question before the council. The secretary-general of the League had to keep the relevant documents available for the members of the council and to transmit to them an annual compilation of all the findings of the minorities committees.

The League of Nations tried to proceed in all minority questions with due regard for the susceptibilities and sovereign rights of the states pledged to the protection of minorities by international treaties. Nevertheless, some of these states resented and opposed the minority treaties or at least repeatedly made the attempt to generalize a system of protection of minorities and to apply it to all states. As a result of Latvian proposals, the assembly of the League of Nations adopted on Sept. 21, 1922, a resolution expressing the hope

That the states which are not bound by any legal obligations to the League with respect to minorities will nevertheless observe in the treatment of their own racial, religious or linguistic minorities at least as high a standard of justice and toleration as is required by any of the treaties and by the regular action of the Council.

When the assembly met for its sixth session in Sept. 1925, the Lithuanian delegation proposed to set up a special committee to prepare a draft convention to include all the states members of the League of Nations, setting forth their common rights and duties in regards to minorities. Only the Rumanian and Polish representatives favoured the proposal, which was finally withdrawn.

At the meeting of the council on Dec. 9, 1925, M. de Mello Franco, the Brazilian delegate and *rapporteur* on minorities questions, expressed himself definitely against generalizing the system for the protection of minorities. He said

The mere co-existence of groups of persons forming collective entities, racially different, in the territory and under the jurisdiction of a state is not sufficient to create the obligation to recognize the existence in that state, side by side with the majority of its population, of a minority requiring a protection entrusted to the League of Nations. In order that a minority, according to the meaning of the present treaties, should exist, it must be the product of struggles, going back for centuries, or perhaps for shorter periods, between certain nationalities, and of the transference of certain territories from one sovereignty to another through successive historic phases.

This definition would exclude all minorities in the two Americas from protection as envisaged by the League of Nations, perhaps with the exception of the Mexican minority in New Mexico and other territories ceded by Mexico to the United States as a result of 19th-century wars.

Though some states which had accepted the minority treaties, such as Poland, owed their existence to the peace treaties of 1919, and though the minority provisions formed an integral part of the peace settlement, these states, especially Rumania and Poland, protested from the beginning against the minority provisions and thereby helped to undermine the whole peace settlement. With the progressive weakening of the peace settlement of 1919 the system of minority protection and the whole League of Nations was weakened. On Sept. 13, 1934, Col. Jozef Beck, Polish minister of foreign affairs, declared that Poland henceforth would refuse to collaborate with the League of Nations in the field of minority protection, and on Nov. 5, 1937, Poland concluded with Germany a bilateral minorities agreement outside the League of Nations.

In Sept. 1934, when Poland refused further co-operation with the League of Nations "in the matter of the supervision of application by Poland of the system of minority protection," a resolution was offered and discussed for extension of the contractual provision of minority protection to all nations, or at least to the whole of Europe. This was the last time that any important debate on the minorities problem was held before the League of Nations. Between July 1, 1938, and June 30, 1939, only four minorities petitions were sent to the League of Nations. Finally in 1939 the minorities section of the secretariat of the League of Nations was liquidated.

**6. Activities of Minorities.**—The minorities themselves tried to protect their rights by forming international organizations. Congresses of "oppressed nationalities" were held in 1912 and 1915 in Paris and in 1916 in Lausanne. After World War I the German minorities took the initiative in forming an international organization of national minorities of Europe, including the minorities not protected by treaties, such as the minorities in Spain, Italy and Germany. The Baltic German Ewald Ammende founded in 1925 the congresses of the organized national minority groups in Europe (outside the Soviet Union). The annual meetings, presided over by the Slovenian Josip Wilfan, were held until 1931 in Geneva, and afterward in Vienna. The last or 14th congress

met in July 1938. These congresses, however, were torn by violent dissensions among the minorities themselves, especially among those who before 1918 had belonged to ruling majorities and those who had then been oppressed by them. As a result of these conflicts, the minorities within Germany, which were not protected by treaty, left the congress as early as Aug. 1927. The German minorities dominated the congresses more and more and turned them into spokesmen for the German cause. In Aug. 1933 the representatives of the Jewish minority left the congress, which threatened to become an organ for irredentist propaganda.

With the growth of German influence throughout Europe, the concept of minority and of its duty of loyalty to the state of which it was a member changed fundamentally, at least as far as the German minorities were concerned. They regarded themselves now openly as members of a *Volksgemeinschaft* which transcended state frontiers. The spokesman of the Union of German *Volksgruppen* declared that:

*Volksgemeinschaft* is not only an identity of language but represents also in the cultural aspect the identity of experience. It would be a denial and an offense against the divinely intended division of mankind into individual folk entities to demand of the *Volksgruppen* that they cut themselves off from the regenerative experience of the main body of their people. Wherever sections of the German people consciously exclude themselves from this experience, the *Volksgemeinschaft* is imperiled (*Nation und Staat*, vol. xi, p. 352).

The blood was regarded as stronger than the citizen's loyalty to the state to which he belonged. The Germans denied that members of different ethnic groups could live peacefully side by side in one and the same state, a supposition accepted as valid in the United States and in western Europe. Prince Bernhard von Bülow, the former German chancellor, wrote in his *Imperial Germany* (New York, 1914, p. 291): "It is a law of life and development in history that where two national civilizations meet they fight for ascendency. . . . In the struggle between nationalities one nation is the hammer, the other the anvil, one is the victor and the other the vanquished." The peace settlement of 1919 and the minorities treaties under the supervision of the League of Nations were animated by the very opposite feeling of the possibility of the peaceful and orderly cohabitation of different nationalities in one state. This was possible only if the 19th-century principles of liberal democracy, constitutional guarantees and mutual tolerance prevailed. Unfortunately these ideas had not yet taken firm root in the soil of central and eastern Europe at the end of World War I.

As a result of this lack of a genuine atmosphere of tolerance in central and eastern Europe, the minorities had frequent cause for complaints which produced numerous petitions to the League of Nations. This body received the largest number of petitions in any single year, namely 204, in the period between July 1, 1930, and June 30, 1931. The most frequent complaints concerned economic discrimination, limitation in the use of minority languages and restriction of educational opportunities. Some of the economic complaints had their origin in economic and social measures which in spite of legal equality worked to the factual disadvantage of the minorities, as in the case of agrarian reforms, when estates owned by members of the minority were divided up among peasant members of the majority, or when new middle and professional classes were helped into existence at the expense of the minorities. In such an atmosphere even a very minor difference of interpretation or any minor shift in the existing balance of power became a source of deep irritation. The vague and much too broad phrasing of the treaties aggravated the situation. But it was not the imperfect letter of the treaties which formed the chief obstacle to a smooth cohabitation of the different minorities and majorities, it was the lack of the right spirit, an obstacle which even a more precise wording of the treaties could not have overcome.

To eliminate the threat which the existence and aspirations of powerful minorities present to the peaceful relations of neighbouring states, the compulsory exchange of minority populations has been suggested. Such an exchange was accomplished successfully between Turkey and Greece. But it was done under unique circumstances which do not easily allow favourable conclusions for general acceptance of the principle involved. The victorious Turks who had driven out the Greek army from Asia Minor, where lived a large and prosperous Greek minority, established since time immemorial, forced the Greeks in the agreement of Jan. 30, 1923, to accept the definite removal of the Greek minority in Turkey, comprising more than 1,000,000 persons, to Greece in exchange for the much smaller number of Turks living in Greece. Religion was to determine the question of who was to be regarded as Greek or Turk. The Greek Orthodox inhabitants of Istanbul and the Muslim inhabitants of western Thrace were allowed to remain in their countries. Mutual property settlements for the benefit of dispossessed persons were supervised by a commission including a majority of neutral members appointed by the League of Nations. The task was made much easier by the fact that far more than 1,000,000 Greek Orthodox citizens of Turkey had fled from Turkey to Greece with the retreating army even before the agreement was concluded. Thus only about 200,000 Christians had to be removed from Turkey and about 350,000 Muslims moved to Turkey under the supervision of the commission, which concluded its work on Jan. 15, 1935.

The League of Nations never ceased to stress the importance of the protection of minorities. When Iraq, after a relatively brief political education under British mandate, was to be admitted in 1932 to the League of Nations as a sovereign state, the Permanent Mandates commission wished to make the independence of mandated territories dependent upon guarantees ensuring the effective protection of racial, linguistic and religious minorities. Iraq, upon entering the League of Nations, declared its acceptance of the protection of minorities. At the council meeting of May 19, 1932, the committee reporting upon the situation of minorities in Iraq declared:

As regards the substantive provisions, the Committee desires first, to emphasize the satisfaction with which it has noted that many of the constitutional and legislative provisions of Iraq are based on a very liberal conception of the rights to be accorded to racial, linguistic and religious minorities. It is happy to recall the fact that during the course of the proceedings, the [Iraqi] Prime Minister made it clear that that conception has as its starting point the idea that all Iraqian nationals, irrespective of race, language or religion, form part, on a footing of equality, of the body of the state.

**7. The Near East.**—With the rise of nationalism and the demand for constitutional rights, under western influence, minority problems began to play a great role in the near and middle east and throughout Asia. At the same time the new nationalism acted as an integrating factor in overcoming the religious cleavages which until the beginning of the 20th century were as dominant in oriental countries as they had been down to the 17th century in Europe. Egypt, a predominantly Muslim country, has a native Christian minority, the Copts. Immediately before World War I much bitter antagonism between majority and minority had flared up. When Great Britain, in accordance with its liberal tendencies, set the example of emancipating colonial countries by granting independence to Egypt on Feb. 28, 1922, it reserved for further discussion the protection of minorities in Egypt. But the fast-growing feeling of national unity fused the Copts with the Muslim majority, so that when the Anglo-Egyptian treaty of alliance was signed on Aug. 22, 1936, no mention was made of the protection of minorities, and Egypt was admitted to the League of Nations on May 26, 1937, without the requirement of a declaration regarding the protection of minorities.

Minorities continued to play a great role in Syria and Lebanon, the part of the Arab world put under French mandate after World War I. The minorities in Syria and Lebanon were religious rather than linguistic minorities, but the difference of religion involved a deep difference in the whole way of life and in the social structure of the various communities which for many centuries had lived in strict segregation. But there too the national Arab movement brought the different Muslim and Christian communities ever more closely together. The Syrian and the Lebanese constitutions included elaborate provisions for the safeguard of the rights of the minorities, and in Lebanon the minorities received a proportionate share in the legislative body, in the administration and in the public service.

Palestine offered a special minority problem of its own. The Arab majority of the country felt itself threatened by the growth

of the Jewish minority, which interpreted the Balfour declaration of Nov. 1917 and the mandate charter of 1922 as a promise for the establishment of a Jewish majority and a Jewish commonwealth in Palestine. The Zionist movement wished to "redeem" the Jews from their permanent and ubiquitous minority status by the creation of a Jewish majority and state in Palestine, the ancient homeland of the Jewish people. The British government had from the beginning rejected the interpretation that the promised "Jewish national home" meant that Palestine would become a Jewish commonwealth. Even the Zionist demand for the promise of the "reconstitution of Palestine as the national home" was rejected in 1917 in drafting the Balfour declaration for the broader and much less definite phrase "the establishment in Palestine of a national home." The British government insisted that the national home must be interpreted in such a limited sense that the interests of the indigenous population should not suffer.

The actual developments, however, did not bear out British expectations. The rise of Hitlerism, which led to a wholesale extermination of Jews not only in Germany but throughout all the lands of central and eastern Europe which fell under German influence or occupation, produced the demand for large-scale Jewish immigration into Palestine. In a resolution adopted at a meeting in New York city the Zionists demanded in 1941 the creation of a Jewish state in the whole of Palestine. The United Nations recommended in 1947 partition of Palestine into an Arab and a Jewish state. The Arab states, however, refused to accept this recommendation and when in 1948 at the termination of the British mandate, the Zionist settlers in Palestine proclaimed the creation of the state of Israel, the Arab states intervened; they were defeated in the ensuing war. About 800,000 Arabs fled from the territory conquered by Israel, and in the 1950s they represented one of the thorniest of refugee problems.

## III. DEVELOPMENTS AFTER WORLD WAR II

Minority questions had received a great deal of attention in the League of Nations after World War I. They were given far less attention by the United Nations after World War II. There was nothing comparable to the minority legislation and minority treaties of the earlier postwar period. On the other hand, the draft covenant on human rights contained articles on the rights of minorities and on the prohibition of advocacy of national, racial or religious hostility. The Commission on Human Rights in the United Nations recommended also that member states uphold the principle of self-determination of all peoples and nations, facilitate the right of self-determination in territories under their administration—preferably through plebiscites under the auspices of the United Nations—and that the general assembly establish a commission to conduct a full survey of the status of the right of peoples to permanent sovereignty over their natural wealth and resources.

The situation of minorities in various countries after World War II constituted a problem of refugees on an infinitely larger scale than before the war. Accordingly, the general assembly of the United Nations established in 1950 an office of the United Nations high commissioner for refugees with his office in Geneva, Switz. His mandate extended to all persons who had fled from their native lands for political, racial or religious reasons and who were unwilling or unable to claim the protection of their own governments. The three main functions of the office were international protection, promoting permanent solutions to the problems of refugees, and administering emergency aid. Separate from this office was the United Nations Relief and Works Agency for the Palestine Refugees in the Near East, with its headquarters in Beirut, Lebanon. Other groups of refugees who did not come under the United Nations office were those in India, Pakistan and in the Federal Republic of Germany. Though they were refugees from their native lands, they were given the full right of citizenship by their countries of residence and were fully integrated in them.

To a degree unknown before modern times, expulsion of minorities from their native lands was used after World War II as a "solution" of minority problems. German minorities in Poland and Czechoslovakia for example, were expelled and most of them settled in western Germany. To a lesser extent the German minorities in Yugoslavia, Hungary and Romania and the Magyar minorities in Czechoslovakia faced a similar fate. Because of these expulsions the problem of minorities in Europe lost much of the great importance it had both before and after World War I. In Europe there were only two minority problems in the 1950s which created domestic and international tensions. The one was the position of the German-speaking South Tirolese in Italy who demanded autonomy and the protection of their economic and administrative position against increasing Italian pressure. The Austrian government made itself the spokesman of the complaints of the South Tirolese who until 1918 had formed part of Austria, and brought their case up in the United Nations at its fall session of 1959.

The other problem was presented by the Turkish minority in Cyprus. This problem became acute when the Greek majority in Cyprus attempted to end the status of the island as a British colony and to become united with Greece. The Turkish minority feared that such a development would undermine its own position. In Feb. 1959 the parties reached an agreement in which the British, Greek and Turkish governments concurred. The Greek Cypriot majority would in effect govern the island, but this agreement gave to the Turks a secure minority position under international guarantee. In 1963 friction between Greek and Turkish Cypriots concerning the government of the five chief towns on the island resulted in an outbreak of fighting and led to the dispatch of a United Nations peace-keeping force to the scene in March 1964.

In Palestine the establishment of the state of Israel over territory largely inhabited by Arabs brought with it a thorny minority problem that contributed to international tension throughout the whole middle eastern area. About 800,000 Arabs who fled from their homeland during the war of 1948 were not allowed to return to their homes, which were now in the state of Israel; over 200,000 Arabs who remained in Israel found themselves in an underprivileged position.

Less acute were the minority problems in Lebanon, which were not based on nationality but on religion, and in Iraq where in the northern part of the country a strong Kurdish minority lived. The various religious groups living in Lebanon enjoyed full equality, and the Kurds in Iraq enjoyed not only equality but also the recognition of autonomy, which was not the case with the Kurdish population in neighbouring Turkey and Iran.

The new nations in Asia had their minority problems, too. The independence of India and the partition of that subcontinent into Pakistan and the Republic of India led to Hindu-Muslim riots, as a result of which many Hindus migrated from Pakistan to India and many Muslims migrated from India to Pakistan. In the Republic of India, divisions by descent and religion as well as language and caste created a number of problems which the Indian government tried to overcome by the principles of democracy and federalism. One of the most vexing minority problems was that of the untouchables in India. The inferior status of this minority had been regarded as sanctioned by the Hindu religion. Although the almost unique, depressed situation of this very large minority, which comprises about 60,000,000 persons, was legally alleviated under British rule and then in the constitution of the Republic of India, by 1960 the force of social tradition was still much too strong to allow a status of equality or full integration of this minority into Indian life.

Other minority problems leading to disputes and even to internal strife were created by the Pathans who lived on both sides of the border of Pakistan and Afghanistan. In the 1950s, Afghanistan made itself the spokesman for the independence of the Pakistani Pathans. In Burma the Karen people demanded independence; their army of national liberation kept up an armed struggle against the Burmese government after the declaration of Burmese independence in 1948. In the Republic of Indonesia various movements for independence or autonomy in the southern Moluccas, Sumatra and Celebes led to much fighting and violent suppression throughout the 1950s. An outstanding example of bitter minority conflicts was supplied by the attempt of the Sinhalese majority in Ceylon to curtail the equality of the Tamil minority. In the Com-

munist Chinese empire the wish for independence or autonomy of the Muslim population in Sinkiang and of the Tibetans was suppressed after bitter fighting.

With the growing desire of the African peoples for independence and with the establishment of a number of African nations in accordance with this desire, various minority problems were created, partly by the fact that tribal and linguistic differences continued in most African countries, and partly by the fact that minorities of white settlers attempted to hinder the wish of the majority of the population for independence or equality. Such obstructionism was apparently successful in South Africa but failed in Algeria.

## IV. MINORITIES IN THE AMERICAS

In the two Americas only the French Canadians in Canada present a minority problem in the European sense of the word. Canada presents the same struggle for the right of language and for economic positions, mitigated by the British traditions of democracy, federalism and tolerance. French was recognized as an official language in 1848 and confirmed in the British North America act of 1867. The French Canadians wished to maintain their own traditional way of life and not fuse with the majority of the Canadian nation.

Such a tendency of segregation and cultivation of differences runs counter to the fundamental policy of the United States, where from the beginning of its nationhood a policy of amalgamation of the different ethnic and linguistic strains forming the new nation was pursued. English was the official language; without any strong pressure in that direction, it quickly supplanted, by the sheer weight of the American tradition, the many languages of the immigrant peoples. From the end of the 18th century on, the United States was regarded as a melting pot where people of the most different origins, religions and languages formed a new nation, based upon a common loyalty and common ideals. This process of assimilation was relatively simple at the beginning. But in the later 19th century, with the rapid growth of immigration, the new immigrants, settled in the large cities in the east and in the agrarian spaciousness of the middle west in compact groups, preserved their own languages, their own national traditions and ideas and partly even their former loyalties. The theory of the melting pot apparently did not work sufficiently well or fast. This new situation created a twofold reaction. Some suggested that the melting pot theory be replaced by the theory of cultural pluralism, which would maintain, within the common political nationhood, the cultural traditions and potential contributions of the various minority groups. Others saw in the rapid growth of the minority groups and in their adherence to their own cultural pattern a danger to the unity of the nation. To preserve the American character, the quota laws of 1921 and 1924 severely restricted immigration to the United States and established quotas in such a way as to strengthen those elements believed most easily assimilable to the American cultural pattern.

But the principle of the melting pot was from the beginning a fundamental factor in the building of the nation, fusing in a spirit of tolerance and liberty various religious and ethnic groups as never had been done in Europe, so that minorities, at least theoretically, became one with the majority in a common cultural tradition and a common political loyalty. As far back as 1782 M. G. J. de Crèvecœur, a French settler in Pennsylvania, stressed in his *Letters From an American Farmer* the variety of groups mingling in the American melting pot:

> What then is the American, this new man? He is either a European, or the descendant of a European; hence that strange mixture of blood, which you will find in no other country. I could point out to you a man, whose grandfather was an Englishman, whose wife was Dutch, whose son married a French woman, and whose present four sons have now four wives of different nations. He is an American, who, leaving behind him all his ancient prejudices, and manners, receives new ones from the new mode of life he has embraced, the new government he obeys, and the new rank he holds. He becomes an American by being received in the broad lap of our great Alma Mater. Here individuals of all nations are melted into a new race of men, whose labors and posterity will one day cause great changes in the world.

And more than a century later Israel Zangwill in his play *The Melting Pot* made one of his characters say:

> Now understand that America is God's crucible, the great melting pot where all the races of Europe are melting and reforming! . . . Yes, east and west, and north and south, the palm and the pine, the pole and the equator, the crescent and the cross-bow, the great Alchemist melts and fuses them with his purging flame! Here shall they all unite to build the Republic of Man and the Kingdom of God.

The minority problems in the United States differ fundamentally from those in central and eastern Europe. Minorities came to the U.S. (with the exception of the Negroes) voluntarily and as individual immigrants, abandoning gladly their homeland and seeking assimilation to higher standards of political liberty and economic equality; their assimilation, always in theory and very often in practice, has been welcomed and facilitated. But there is no doubt that ethnocentricity and strong group solidarity within some of the immigrant groups, and prejudice on the part of the majority, have often strained the relations between majority and minorities. Evidence of incomplete assimilation among minority groups was widespread in World War I, though much less in World War II, and has sometimes presented a real danger. Conscious and well-organized propaganda on the part of the German and Italian governments preceding World War II threatened to undermine the loyalty of the German and Italian minorities. The events of World War II, however, proved that in the overwhelming number of cases even those minorities whose conationals in Europe or Asia fought against the United States remained loyal to the United States and that the process of assimilation had taken much deeper root than many had supposed. With the act of 1924 the period of large-scale immigration to the United States came to an end. The attitude of the first-generation minority groups, fusing themselves completely with the majority, was well expressed in 1937 by one of the prominent foreign-born citizens of the country, Aleš Hrdlička, when he declared of America:

> It received them without any sentiment, without any care, often, perhaps, with outright neglect and selfishness. But it gave them freely of the precious new air of spiritual liberty. It dealt with them perhaps at times rudely, but frankly. It gave them a chance, a chance to educate themselves and their children, a chance to progress in every direction if they were willing and capable. What wonder that with all the initial difficulties and even sufferings, so many of the immigrants became deeply grateful to the country of their adoption, became fused with it like so many wholesome grafts on a healthy virile tree, and became within less than a generation true, loyal Americans.

The most difficult minority problems of the United States are presented by the factual and sometimes even legal position of the nonwhite minorities—Negroes, Asians and American Indians. In Latin-American countries minority problems are of a twofold character: in some of them large European immigrant groups have yet to be fully integrated into the cultural pattern and the political loyalty of their new country; in others the numerical majority of native Indians live, as regards actual political rights, educational facilities and economic opportunities, in the status of an underprivileged minority.

## V. CONCLUSION

With all the diversity of the positions and problems of minorities all over the world, it can be said that in the 20th century the awareness of the rights of minorities to equal opportunities grew, in spite of the fact that German national socialism and other totalitarian movements, on behalf of the absolute authority and uniformity of the state, rejected the liberty and equality of minority groups. These tendencies represented the most extreme form of racial or ideological (or religious) exclusivism. Only the growth of the liberal tradition of individual liberty and tolerance can solve the minority problems in a form acceptable to the conscience of civilized humanity.

**MINOR PLANET:** *see* ASTEROIDS.

**MINOS,** a legendary ruler of Crete. Difficulties with genealogies led some ancient myth writers to distinguish between Minos the Elder and a grandson, Minos the Younger, a discrimination never observed in the myths themselves. He was the son of Zeus and Europa and, after expelling his brother Sarpedon (*q.v.*), obtained the Cretan throne by the aid of Poseidon. From Knossos (or Gortyna in some Latin authors) he gained control over the islands of the Aegean, colonized many (Thucydides i. 4), and cleared the sea of pirates. He established wise laws, was venerated as a friend of Zeus and, apparently, ruled in eight- or nine-year terms (*Odyssey*, xix. 178–179). He married Pasiphaë, the daughter of the Sun, who bore him, among others, Androgeos, Ariadne and Phaedra. Minos was punished by the gods for refusing to sacrifice a certain bull. Especially in the Athenian tradition, Pasiphaë became enamoured of the creature and bore the Minotaur (*q.v.*). In other legends the bull ravaged the land of Crete. Minos later went to war against Athens, according to many sources to obtain redress after his son Androgeos was killed. After capturing Megara by the treachery of Scylla, who cut off the lock of purple hair by virtue of which her father, Nisus (*q.v.*), the king, had been unconquerable, Minos forced the Athenians to surrender. In Athenian drama and legend Minos becomes the tyrannical and heartless exactor of the tribute of children to feed the Minotaur until Theseus slew it in the Labyrinth. Minos died in Sicily, where he had gone in pursuit of Daedalus, who had built the Labyrinth. The daughters of King Cocalus poured boiling water over him as he was taking a bath. After his death he became a judge in Hades, along with Aeacus and Rhadamanthus.

Although Athens preserved a hostile tradition (Plutarch, *Theseus*, 16), the general account shows Minos as a powerful, just ruler (Diodorus, v. 78) very closely associated with religion and ritual. In light of the excavations in Crete, many scholars consider that Minos was a royal or dynastic title for the priestly rulers of Bronze Age or "Minoan" Knossos. Probably various traditions were ascribed to one name, and thus memories were preserved of an early Cretan power which seems to have been important at sea and was regarded with mixed feelings of respect, awe and hatred. *See* also references under "Minos" in the Index.

**MINOT, GEORGE RICHARDS** (1885–1950), U.S. physician and co-winner of a Nobel prize for his work on liver therapy in pernicious anemia, was born at Boston, Mass., on Dec. 2, 1885. He received his medical degree from Harvard university in 1912. After serving as intern at Massachusetts General hospital in Boston, he became resident at Johns Hopkins hospital, Baltimore, Md., and next year research fellow in physiology at Johns Hopkins, under William H. Howell. In 1915 he returned to Boston and continued work on transfusion and disorders of the blood while serving on the medical staff of the Massachusetts General hospital until 1923. In 1921 he developed severe diabetes and was among the first patients in Boston to receive insulin. After appointments at the Huntington Memorial (cancer) and Peter Bent Brigham hospitals, he became in 1928 professor of medicine at Harvard and director of the Thorndike Memorial laboratory at Boston City hospital.

Minot and another Boston physician, William Parry Murphy (*q.v.*), by systematically employing a liver diet, achieved in 1926 the first successful treatment of pernicious anemia. This followed earlier nutritional experiments of the pathologist George Hoyt Whipple (*q.v.*) on dogs kept anemic by bleeding, and in 1934 all three shared the Nobel prize in medicine. Meanwhile, with the physical chemist Edwin J. Cohn, Minot had prepared efficient liver extracts. His research on anemia and nutritional disturbances continued at the Thorndike Memorial laboratory, where many subsequent leaders in U.S. medicine came under his influence. Minot died in Brookline, Mass., on Feb. 25, 1950.

**MINOT, LAURENCE** (fl. 1333–1352), English poet, was the author of 11 battle songs, first published by Joseph Ritson in 1795 as *Poems on Interesting Events in the Reign of King Edward III.* These had been discovered by Thomas Tyrwhitt in an early 15th-century manuscript (Cotton. Galba E. IX., British museum) which contains many other poems. Minot's poems were evidently written contemporaneously with the events they describe. The first celebrates the English triumph at Halidon hill (1333) and the last the capture of Guines (1352). Nothing whatever is known of Minot's life, but the minuteness of his information suggests that he accompanied Edward on some of his campaigns. The poems are vigorously, if somewhat crudely, written in heavily alliterated rhyming verse. The language of the manuscript is northern, with some midland features.

*See* the ed. of Minot's poems by J. Hall (1887; 3rd ed., 1914). (X.; N. D.)

**MINOT,** a city of North Dakota, U.S., 55 mi. S. of the Canadian border on the Souris river, is the seat of Ward county. Settled in 1886 when the Great Northern railroad reached the Souris, Minot had 5,000 inhabitants within a year and was incorporated as a city in 1887. Because of its location in the short-grass ranching country, cowboys and horse and cattle thieves gave it a "wild west" atmosphere. After 1892, when its hinterland, about the size of Indiana, was opened to homesteaders, it became the largest city and the leading retail and wholesale centre between the Red River valley and Great Falls, Mont. A steady population increase was brought about by the growth of small industries, lignite shipment and the location of a U.S. air force base nearby. (For comparative population figures *see* table in NORTH DAKOTA: *Population*.)

Minot's business centre is built on the flood plain of the Souris, which winds eight miles through the city. The rugged hills up which it has spread give Minot a striking appearance uncommon on the plains. The North Dakota State Teachers college opened there in 1913. There are 300 ac. of parks, one of which, Roosevelt, contains a large zoo. Minot has a council-manager form of government in effect since 1933. Its name is in honour of Henry D. Minot, eastern capitalist and friend of Theodore Roosevelt. (R. P. Wi.)

**MINOTAUR** (Gr. *Mino Tauros*, "Minos' bull"), in Greek mythology, a fabulous monster in Crete having the body of a man and the head of a bull. This creature was supposed to be the offspring of Pasiphaë, the wife of Minos (*q.v.*), king of Crete, and a snow-white bull sent to Minos by Poseidon for sacrifice. Minos, instead of sacrificing it, kept it alive; Poseidon as a punishment made Pasiphaë fall in love with it, and with the help of Daedalus she disguised herself as a cow. Her child by the bull was shut up in the Labyrinth (*q.v.*).

MINOTAUR. DETAIL FROM PAINTING ON A GREEK AMPHORA. IN THE BRITISH MUSEUM

It happened that Androgeos, son of Minos, had been killed by the Athenians, who were jealous of the victories he had won at the Panathenaic festival. To avenge the death of Androgeos, Minos demanded that seven Athenian youths and seven maidens should be sent every ninth year (alternatively, every year) to be devoured by the Minotaur. When the third sacrifice came round Theseus (*q.v.*) volunteered to go, and with the help of Ariadne (*q.v.*) killed the Minotaur.

It seems probable that the legend is in some way connected with the ceremonial bull leaping represented on Cretan frescoes, sealstones, etc., which was perhaps a sacred rite. Representations of half-human monsters are also common in late Minoan art.

**MINSK,** an *oblast* (established 1938) of the Belorussian Soviet Socialist Republic, U.S.S.R., covers an area of 15,830 sq mi. in central Belorussia. Along its northwest are the rolling hills of terminal moraine which form the Belorussian ridge (Belorusskaya Gryada) and rise to 1,135 ft. in Mt. Dzerzhinskaya on the Minsk upland (Minskaya Vozvyshennost). From the ridge the central Berezina plain slopes gently to the southeast, drained by the Berezina, its tributary the Svisloch and tributaries of the Pripyat (Pripet).

The mixed forest cover of the upland has been almost wholly cleared for agriculture and gully erosion has developed, but the plain is still thickly forested in many areas with pine, spruce, oak, birch and, in wetter areas, with alder. Swamps, both grass marsh and peat bogs, are widespread, especially in the south and east. Soils are usually podsols.

The population numbered 1,982,519 in 1959, of whom 782,072 (39.5) were urban, mostly concentrated in Minsk (509,489). The other 12 towns and 25 urban districts are all small. The largest is Borisov (59,250). Industry is chiefly concentrated in Minsk, although Borisov is an important timber-working centre. Other towns are mostly concerned with processing farm and forest products. Timber cutting is well developed. Arable land is found mainly on the uplands and around Slutsk in the south. Rye, wheat, buckwheat, barley and flax are the chief crops. Animal husbandry, especially dairying, is important. (R. A. F.)

**MINSK,** the capital and largest city of the Belorussian Soviet Socialist Republic, U.S.S.R. and administrative centre of an *oblast*, stands on the Svisloch river. Pop. (1959) 509,489. The first documentary evidence refers to Mensk or Menesk in 1067. In 1101 it became the seat of a principality. The town was often sacked and in the 14th century passed to the grand duchy of Lithuania and later to Poland. In 1505 it was laid waste by the Crimean Tatars, and destroyed by fire in 1546 and several times in the 17th century. Russia acquired Minsk by the second partition of Poland (1793) and made it the seat of a *guberniya* (province). In 1812 it was occupied by Napoleon's troops and again suffered damage. The building of the Moscow-Warsaw and Vilnius-Gomel railways through Minsk in 1871 accelerated its growth from 6,656 inhabitants in 1800 to 90,912 in 1897. Minsk underwent three further occupations: by the Germans in 1918, the Poles in 1919–20 and the Germans again in World War II. In the Soviet advance of 1944 heavy fighting took place in the city and it was almost entirely destroyed. Modern Minsk consists almost wholly of new buildings in the postwar Soviet architectural style, and few relics of the past survive. Still in existence are the Mariinski cathedral and the church of the Bernadine monastery, and the small house, now preserved as a museum, where the first congress of the Russian Social Democratic (Revolutionary) party met in 1898.

A major industrial centre, Minsk's wide range of products includes heavy and tipper trucks, timber wagons, tractors, motorcycles, machine tools, radio and television equipment, bearings, footwear and leather goods, clothing, chinaware, pharmaceutical goods, furniture, spirits, tobacco and foodstuffs. It is an important printing centre. Among many cultural institutions are the Belorussian Academy of Sciences, an academy of agricultural sciences, the V. I. Lenin State university (1921) and 11 other higher educational institutes. There are a ballet and opera theatre, a musical conservatoire and Russian and Belorussian theatres. (R. A. F.)

**MINSTREL** (from Old French *ménestrier*), in popular usage a general name for secular musicians of earlier times. More precisely, it was the normal term for a professional secular musician of any kind in the 13th and 14th centuries. During the 15th century, which brought the rapid development of formal part music and specialized ensembles, its use tended to be restricted to those musicians who did not fulfill a specialized function. In the 16th century it came to mean a somewhat disreputable itinerant musician, and by the 17th it ceased to be a meaningful term.

In western Europe until about the 11th century music was not a separate entity but an adjunct to the church liturgy and, in secular life, to dancing and to the chanting of long heroic or satirical tales. The indigenous instruments were simple lyres (robust survivals from classical antiquity), whistle flutes of Neolithic ancestry, panpipes and animal horns with or without fingerholes. During the 11th century, when the feudal structure of France and England was consolidated, there emerged a class of general entertainers called *jongleurs* (Old French), who sang and had some skill on instruments but who were also acrobats, jugglers and trainers of performing animals. The nature of secular music changed considerably after the 12th century, following the sophisticated flowering in the songs and dances of the troubadours and trouvères, and the infiltration of instruments of Arab origin, such as lutes, psalteries, fiddles and rebecs, shawms, trumpets and drums. The word minstrel began to be used, apparently for an executant of more specifically musical skill than the jongleur.

A court minstrel was expected to play many instruments; the troubadour Giraut de Calanson (fl. *c.* 1210) lists citole, monochord, fiddle, mandore, pipe and tabor, and bagpipe among them. It is likely that less exalted minstrels were less well equipped. There were certain regional preferences in instruments, the harp in the British Isles, for example, and the vièle, or troubadour fiddle, in France and Germany. In the music of that time, although unspecified as to instrumentation, there are characteristic pieces for every type of instrument. The minstrel's *expertise* was learned as a craft. No exact records survive of the instrumental practice of those days, though much may be deduced from current techniques on folk survivals of medieval instruments. Besides the minstrels attached to royal and noble households, there were, in

the 14th century, large numbers of free-lance minstrels employed when necessary by city and town authorities for their lavish entertainments, by ecclesiastical authorities and by wealthy private citizens. In 1321 the minstrels of Paris formed a corporation and were affluent enough to open a hospice for poor minstrels in 1330 and to build a church, St. Julien-des-Ménestriers, begun in 1331. London minstrels formed a guild in 1350.

The nature of the minstrel's art, of individual and largely extemporized virtuosity on several instruments of strong and unblending tone quality, was not in keeping with the organized concerted part music which developed in the 15th century, and although the word continued to be used in a general sense, players of a specialized kind, such as those in shawm and sackbut ensembles used for some dance and ceremonial music, string players, royal trumpeters and virtuoso harpers, were often identified as such and not as minstrels. In 1469 Edward IV of England granted letters patent incorporating the Musicians' Company of the City of London, but during the next 60 years the London minstrels, declining in prosperity and prestige, twice made enactments against the activities of foreign minstrels within the city, demanding a fine of 3*s.* 4*d.* In England the word minstrel acquired its final disreputable meaning during the latter half of the 16th century. In France the minstrels' guild maintained an archaic and nebulous existence until its authority was challenged and overthrown by the professionally organized harpsichordists, organists and violinists of the mid-17th century. The harpsichord suite by François Couperin, "Les Fastes de la Grande et Ancienne Mxnxstrxndxsx," is a musical satire on the French minstrels' guild.

**MINSTREL SHOW.** Negro minstrelsy, the only indigenous American theatrical form, was based upon the singing and dancing of Negro slaves. While in its early forms the minstrel show often presented accurate delineations of southern Negro types, later forms showed diminishing relationship to Negro life and feeling.

Individual Negro impersonators appeared early in the 19th century, the most famous being Thomas Dartmouth Rice, whose "Jim Crow" song and dance was first performed in 1828. The pioneer company, the Virginia minstrels, a quartet headed by Daniel Decatur Emmett, first performed in Jan. 1843. Emmett, who wrote "Dixie" as a "hooray song" or "walk-around" in 1859, became one of the more prominent minstrel performers. The most important of the early companies was the Christy minstrels. Organized in Buffalo, N.Y., they were in New York city by 1846, and, in 1847, leased Mechanics hall on Broadway, where they played for nearly ten years. Stephen Foster wrote his greatest songs for this company. Other noted companies were Bryant's, Campbell's and Haverly's. Negro minstrelsy, popular in England as well as the U.S., reached its zenith between 1850 and 1870, then gradually declined until it became purely a vehicle for amateurs. Its influence, however, was sometimes evident in vaudeville, radio, television and motion pictures of the mid-20th century.

The form of the minstrel show was established by the Christy company and changed little thereafter. The performance usually was in two parts. In part one, the performers were arranged in a semicircle, with the "interlocutor" in the centre, and the endmen, "Mr. Tambo," who played the tambourine, and "Mr. Bones," who rattled the bones, at the ends. The interlocutor, played whiteface, usually wore full dress, the others, their faces blackened with burnt cork, wore gaudy swallow-tailed coats and striped trousers. The program opened with a chorus, often with a grand entrance, and at the conclusion of the song, the interlocutor gave the stereotyped command, "Gentlemen, be seated." Then followed a series of jokes between the interlocutor and endmen, interspersed with ballads and comic songs and instrumental numbers, chiefly on the banjo and violin. The second part, or olio, consisted of a series of individual acts which concluded with a "hoe-down" or "walk-around" in which every member of the company did a specialty number while the others sang and clapped. Occasionally there was a third part, consisting of a farce, burlesque or comic opera. Sometimes this feature was made the last item of part two.

The minstrel show disappeared from the professional theatre. Its chief significance lay in its "folk" music, which made a permanent contribution to American culture. (C. I. S.)

**MINT,** a place where coins are manufactured, usually with the authority of the state.

**History of Development.**—The first state mint was probably established by Candaules (Sadyattes) king of Lydia in Asia Minor, or by his successor Gyges, early in the 7th century B.C. The example of the Lydians was soon followed by the Greeks of the Aegean Islands, and from there the art of coining quickly spread into Italy and other Mediterranean countries, as well as to Persia and India. The Romans, who began coining in the 4th century B.C., laid the foundations of modern minting. Coining also originated independently in China in the 7th century B.C. and soon spread into Japan and Korea.

Gold, silver and base metal coins were in use by various tribes in Britain before the Roman occupation. The Romans attempted unsuccessfully to suppress the tribal mints, but in the 3rd century A.D. the Emperor Marcus Aurelius Carausius himself opened three English mints, one of which was in London. They were soon closed, however, and not until the 6th century was there further definite record of a mint in England. By the reign of Alfred the Great there were at least eight mints in operation, and at the time of the Norman conquest there were more than 70 mints. The number was so large because most of the principal towns throughout the land were authorized to appoint their own "moneyers," *i.e.*, men who struck official coins by hand for local use. This policy was dictated by the fact that the transport of money from one city to another was risky, for road communications were very poor at this period of history and the countryside was infested by roaming robber bands. The number of mints later declined and since the 16th century all gold and silver coins, with one or two important exceptions, *e.g.*, the Great Recoinage of 1696 to 1698, have been struck in the London mint. Early in the 19th century the London mint moved out of the Tower of London, where it had been housed for five centuries, to its own premises on Tower Hill, not far away.

With the colonization of South America and Mexico by the Spaniards in the 16th century, mints were set up in these lands to utilize the gold and silver available there, particularly in Peru and Mexico. The early English colonists in Massachusetts started striking their own silver coins in the form of shillings in the 17th century. There have been seven coinage mints at various times in the United States since the establishment under the constitution of the first mint in Philadelphia in 1792, but only two mints were in operation in the mid-1960s, one in Philadelphia and the other in Denver, Colo. The latter had been established in 1906. A third mint in San Francisco, Calif., discontinued coinage in 1955.

Canada and many other countries throughout the world also operate mints of their own, but some, usually those where the demand for coins is not sufficient to make a national mint economically feasible, have their coins made in foreign mints. The London mint first struck coins for other countries in the 16th century. U.S. mints were authorized by congress in 1874 to contract for foreign coinage orders.

Functions other than minting, notably refining precious metals and manufacturing medals and seals, are performed by many mints. The U.S. mints provide storage for government stocks of gold and silver and the London mint assists in the maintenance of hallmarking standards by examining samples submitted by the provincial assay offices in England and Scotland. The London mint maintains a continuous program of research on coinage materials and processes.

**History of Technique.**—The method of preparing dies and striking coins continued more or less unchanged until the 15th century. Early coins were produced by being struck with a hammer. The lower die, or pile, was given a spiked end so that it

could be firmly driven into a large block of wood; a blank piece of metal of the required size would then be placed on the pile, with the hand-held upper die, or trussel, on top. When the trussel was struck one or more blows with a hammer the whole design was impressed on the blank. It was not until the 15th century, in Italy, that some degree of mechanization was evolved. Rolls for reducing the thickness of cast bars, machines for punching out blanks from sheets of metal and screw presses for striking coins were introduced into the Paris mint in the early 1550s, but it was only in the reign of Charles II (1660–85) that the use of the hammer was abandoned in the London mint. The screw presses were fed and often powered by hand but toward the end of the 18th century a method was devised by Matthew Boulton whereby basically similar presses were driven by steam and were automatically fed with blanks. Screw presses were displaced following the invention of the lever press in 1839. Minting by hand, however, persisted in the native states of India until the end of the 19th century.

In the 15th century the process of manufacture of dies was changed. Whereas in the past a series of punches had been used to build up the design on each individual die, the engraver now prepared a relief punch of the complete design, from which many standardized dies could be made. During the 19th century the practice of engraving punches was abandoned and designs were engraved in intaglio to produce master dies or matrices, and machinery was introduced by which it became possible to engrave master tools mechanically from models several times coin size.

**Modern Processes.**—Mints use furnaces heated by gas, oil, coke or electricity to melt raw materials and process scrap. The metal is cast into molds to obtain bars or slabs ranging in weight from a few pounds—for precious metals requiring very accurate control of composition—up to several hundred pounds—for base metal alloys that do not require such close control of composition.

Small bars are reduced to coin thickness by cold rolling, but a combination of hot and cold rolling, employing highly mechanized equipment, is needed to process large bars. Progressive hardening of the metal occurs during rolling, and it is nearly always necessary to soften it by annealing (heating and cooling) before rolling can be completed. The annealing temperature and time depend on the alloy, but are generally in the range 600°–900° C. for 20 minutes to 3 hours. Partly rolled bars are sometimes surface-machined to remove blemishes and to achieve uniform thickness across the width.

When the bars have been reduced to strip of coin thickness they are passed through blanking presses to produce coin size disks. Cutting or blanking entails the shearing of circular or shaped blanks from the strip by the penetration of cylindrical or shaped punches through the metal into matching holes cut in a bedplate. Multiple blanking is employed, the number of blanks produced at a stroke depending upon the machine capacity, strip width and thickness, and blank size. Normally, from four to ten blanks are cut at one stroke. The blanks are annealed and cleaned by acid pickling, washing, burnishing and drying to produce a bright finish.

Blank annealing is carried out in muffle furnaces of the rotary drum or conveyor belt type. The blanks move through hot zones which may have a controlled reducing or neutral atmosphere to minimize oxidation. Annealing temperatures vary from 500° to 900° C., according to the alloy.

Pickling to remove the oxide film formed during annealing is a chemical process in which the blanks are placed in a rotating drum containing diluted sulfuric acid to which is added bichromate of soda. The blanks are then passed to a rotating air dryer, or are dried with sawdust.

The impressing of the designs on the blanks takes place in coining presses capable of applying a load of 250 tons. The blanks are fed automatically onto the face of a die bearing one of the designs, and the other die is then brought under load into contact with the upper side of the blank, thus causing both designs to be stamped simultaneously. The blow is sufficient to cause the metal to spread outward into the shape of a collar which surrounds the blank at the moment of impact. The hole in the collar is slightly larger than the blank and may be plain on its inside surface or bear the milled pattern familiar on many white coins. Provided that the deformation required is not too great, polygonal (*e.g.*, 12-sided) coins can in this way be struck from circular blanks; shaped blanks are necessary, however, when it is desired to produce coins whose shape is markedly different from a circle.

Coining presses vary in design, but they rely basically on a toggle lever system to transfer the power from the drive to the striking mechanism. Automatic feed mechanisms vary in design also, from a mechanical version of the "finger-and-thumb" location, to rotary disk location of blanks. These mechanisms are in turn fed manually or automatically.

To protect the designs and facilitate stacking, coins generally have a raised rim. This is imparted in the striking process, but in order to reduce the amount of metal that has to be moved in striking, the blanks are often edge-thickened by a separate and earlier process called marking. In this, the blanks are rotated between a static segment and a rotating crown wheel mounted to give an annulus narrower than the diameter of the blank. Segments are usually plain but may bear letters or patterns which in the process are raised or more commonly imprinted on the edges of the blanks. Blanks bearing a raised pattern cannot be struck in a collar, and a more common process of producing coins with raised patterned edges is to have the patterns engraved on the inside of the collars used in striking. To allow the coins to be ejected, such collars are made in segments and open after striking.

Designs for coins are usually fashioned in the first instance by an artist working in clay or plasticine several times coin size. A plaster cast is taken from the artist's model and from it a replica is made, usually in bronze if it is cast or made by electrodeposition. Nickel is deposited first to give hardness and is followed by copper to give thickness for strength.

The metal copy is mounted on a machine on which its details are scanned in a fine spiral by a tracer fixed to the free end of a pivoted bar. A rotating cutter is also mounted on the bar nearer to the pivot. The cutter repeats the tracer's movements in proportion to the distance of each from the pivot, cutting a reduced-size copy in a softened steel block. All identical patterns, such as portraits on a series of coins, may thus be reproduced in different sizes by changing the relative positions on the bar of the cutter and tracer. The spiral path of the tracer and cutter is achieved by synchronized rotation of the model and tool-steel, combined with a gradual movement of the bar across their face.

The tool produced on the reducing machine, known as a reduction punch, is touched up by hand engraving, hardened and used to make a matrix which is itself used to make a working punch, and this in turn is used to make working dies. All these processes are carried out with the aid of a screw or hydraulic press, with hand engraving as necessary to maintain or modify the detail of the original model. Hand engraving may also be employed to introduce features not on the original model (*e.g.*, beads), to effect a change of date, and occasionally to cut a complete design into a matrix without resort to a model.

**Alloys.**—Until the 19th century, coins were usually made of gold, silver or copper, and normally their intrinsic value was equal to their face value. The earliest gold and silver coins made by the Greeks consisted of the pure metals or of electrum, a natural alloy of gold and silver; under the Roman emperors copper was intentionally added. The amount of alloy added to gold has varied considerably; some Roman coins contained only 2% of gold. The gold standard of 916.6 parts per 1,000 was adopted in England in 1526, though not exclusively until the next century. United States gold coins were struck in 900 standard gold, an alloy introduced in France soon after the French Revolution and later adopted in most other countries. A wide variety of standards of silver have also been used for coinage. The silver alloy of a fineness of 925 parts per 1,000 was probably introduced first in England by the Saxons and continued to be used until the 20th century, though on occasion the fineness of silver was deliberately reduced. In 1920 the standard of 500 was introduced, and after 1946 silver was abandoned altogether except for certain small special issues.

United States silver coins are of a fineness of 900 parts per 1,000. Other countries have used silver alloys ranging from almost pure silver to 250 parts per 1,000 or less.

With the acceptance of the idea of token coins—the bullion value of which is less than the face value—the field was opened to cheaper metals, though not to the total exclusion of the traditional alloys. Cupro-nickel, which replaced silver in England, was adopted by Belgium in 1860 and thereafter came into use throughout the world. Copper was generally used in the past for subsidiary coins, but in the 19th century it was largely replaced by bronze, an alloy of copper, tin and zinc. Of increasing importance in recent years have been aluminum alloys, brasses, pure nickel, stainless steel and clad steel (steel coated in sheet form with nonferrous metal). Zinc has been used mainly in times of emergency, as during World Wars I and II. (*See* also ALLOYS.)

**Inspection and Quality Control.**—To counter the threat of counterfeiting, as well as for other reasons, rigid dimensional and composition controls are imposed on the manufacture of coins; exact compositions, weights and tolerances are usually specified by law. Assay samples are taken from each cast of metal, at any process where the composition may be changed (*e.g.*, pickling), and, of course, from the finished coin. Dimensional control is usually exercised only on diameter, thickness being indeterminable because of design variations. Checks on weight are carried out at the cutting, blanching and postcoining stages. Depending on the intrinsic value of the coin, weight tolerances may be specified as applying to bulk samples or to individual pieces.

Superficial inspection of blanks and coins may be performed visually. This is facilitated by a system of belt conveyors upon which the blanks are spread in a narrow band, and which automatically turn them over to permit inspection of both sides in succession. Because of inherent difficulties in the casting process, gas inclusions may occur and give rise to pieces that are superficially perfect but are in fact split in the plane of the metal and therefore "dumb." Checks on this defect are maintained by inducing samples of the coins to resonate by bouncing them on a metal block.

The use of precious metals, and the direct relationship between face value and intrinsic value made desirable independent checks on the weight and composition of coins. Such checks were made from very early times in England by persons appointed by the crown, and the finding of any deficiency in weight or fineness often meant severe punishment for the moneyers, or minters. The check, known as the Trial of the Pyx, is still performed annually by the Company of Goldsmiths on samples of all United Kingdom gold, silver and cupro-nickel coins minted in the preceding year.

In the United States the Assay commission, appointed by the president, meets in February each year to examine and test the weight and fineness of the silver coins reserved at the Philadelphia and Denver mints during the preceding calendar year. The coins, one from each 2,000 pieces or fraction thereof made at each mint, are deposited in sealed packages in a so-called pyx or box for delivery to the commission. *See* also NUMISMATICS.

MT.)

**MINT,** the common name for strong-scented herbs of the genus *Mentha*, comprising about 25 species of perennial herbs, and certain related genera belonging to the mint family (Labiatae; *q.v.*). Mints are widely distributed throughout the temperate and subtropical portions of the globe, but chiefly in the temperate regions of the old world.

**True Mints.**—*Mentha* species have square stems, opposite, aromatic leaves, and a stoloniferous creeping rootstock. The flowers are arranged in axillary clusters, which either form separate whorls or are crowded together into a terminal spike. The corolla is usually small and of a pale purple or pinkish colour; it has four nearly equal lobes and encloses two long and two short stamens. All the genus *Mentha* abound in a volatile oil, contained in resinous dots in the leaves and stems. Most mints blossom in summer.

Although native to northern Eurasia and Australia, *Mentha* has a number of species naturalized in North America. The forms easily hybridize so that there is great confusion in the genus. *Mentha spicata* is the common garden mint or spearmint (*q.v.*), which is commonly used for culinary purposes; it is distinguished by its smooth, sessile leaves and lax tapering flower spikes. *Mentha longifolia* chiefly differs from the above in its coarser habit and hairy leaves, which are silky beneath, and in its denser flower spikes. This plant is supposed to be the mint of Scripture, since it is extensively cultivated in the east; it was one of the bitter herbs with which the paschal lamb was eaten. The water mint (*M. aquatica*) grows in ditches and is easily recognized by its rounded flower spikes and stalked hairy leaves. Peppermint (*q.v.*; *M. piperita*) has stalked smooth leaves and an oblong obtuse terminal spike of flowers; it is cultivated for its volatile oil. *M. crispa* belongs to a group in which the flowers are arranged in axillary whorls and never in terminal spikes; it otherwise bears some resemblance to *M. spicata*.

*M. pulegium*, commonly known as pennyroyal (*q.v.*), has small oval obtuse leaves and flowers in axillary whorls and is remarkable for its creeping habit and peculiar odour. It was formerly popular for medicinal purposes.

**Other Mints.**—The name mint is also applied to plants of other members of the family: *Monarda*, the bergamots, are called horsemint; *Pycnanthemum* mountain mint; *Nepeta cataria*, the catnip, is sometimes called catmint; *Cunila origanoides* is the stone mint or Maryland dittany of garden borders; *Prostanthera* species are tender Australian shrubs called mint bushes.

**MINTO, GILBERT ELLIOT-MURRAY-KYNYNMOUND,** 1ST EARL OF (1751–1814), governor general of India from 1806 to 1813, was born on April 23, 1751, the eldest son of Sir George Elliot. About 1763 Gilbert and his brother Hugh were sent to Paris where their studies were supervised by the noted philosopher, David Hume, then secretary to the British embassy in Paris. The brothers also became friendly with the comte de Mirabeau at this time. Returning to England, Gilbert entered Christ Church, Oxford, and then Lincoln's Inn, and was called to the bar in 1774. He entered parliament two years later as an independent Whig; became friendly with Edmund Burke, whom he helped in the attack on Warren Hastings and Sir Elijah Impey, and on two occasions was an unsuccessful candidate for the office of speaker. Elliot was appointed to govern Corsica in 1794; he assumed the additional names of Murray Kynynmound (from his mother's family) and was created Baron Minto in 1798. From 1799 to 1801 he was envoy-extraordinary to Vienna, and having been for a few months president of the board of control he was appointed governor general of India at the end of 1806. During his rule he had to provide against the danger from Napoleon, and deal with the nearer menace of the Sikh power at Lahore. Before he gave up office in 1813 Java and the Moluccas had been added temporarily to the empire. He was then created Viscount Melgund and earl of Minto. He died at Stevenage on June 21, 1814, and was buried in Westminster abbey.

(1874), *Lord Minto in India, 1807–1814* (1880); Sir J. F. Stephen, *The Story of Nuncomar and the Impeachment of Sir E. Impey* (1885). (T. G. P. S.)

**MINTO, GILBERT JOHN ELLIOT-MURRAY-KYNYNMOUND,** 4TH EARL OF (1845–1914), governor general of Canada and viceroy of India, where he introduced the Morley-Minto reforms in 1909. He was born in London on July 9, 1845, the eldest son of the 3rd earl, and was educated at Eton and Trinity college, Cambridge. He joined the Scots guards in 1867 but obtained his discharge in 1870 in order to devote himself to riding; after breaking his neck in his fourth Grand National in 1876, however, he gave up serious riding. As a newspaper correspondent he was in Spain with the Carlist army in 1874, and then in Turkey in 1877 during the war with Russia. He was present in an unofficial capacity during part of the second Afghan War in 1879 and fought in the Egyptian campaign in 1882. He went to Canada in 1883 as military secretary to Lord Lansdowne, and served in the campaign against the rebellion of Louis Riel. He returned to England in

1886 and succeeded his father in 1891. He was appointed governor general of Canada in 1898, where his tact and knowledge of affairs enabled him to moderate the conflicts that arose between the imperialism of Joseph Chamberlain, the colonial secretary, and the nationalism of Sir Wilfred Laurier, the prime minister of Canada. He deprecated an excessive concentration on party politics and he never hesitated to proffer his advice to the prime minister on public questions, but Laurier himself paid tribute to his invariably constitutional behaviour.

Minto returned to England in 1904 and was appointed viceroy of India in 1905. Again he had to work with a forceful and opinionated secretary of state, John Morley (*see* MORLEY, JOHN MORLEY, Viscount), who was at the India office. But as the effective head of the government of India his own powers and responsibilities were much greater than they had been in Canada. His political ideas were much less radical than Morley's but the necessities of the time generally brought the two of them into some sort of agreement. In spite of occasional differences and in spite of Morley's autocratic temperament, their partnership was remarkably successful, largely because of Minto's tact and restraint. Many of the policies initiated by Minto's predecessor, Lord Curzon, had aroused hostility among the Indian nationalists. Minto and Morley were agreed that some political reforms were essential, both to satisfy the demands of educated Indians and also to strengthen the hands of the moderate leaders of the Congress party and prevent the rising tide of nationalism from being diverted into extremist or even terrorist channels. Two Indian members were appointed to the secretary of state's council and one to the viceroy's executive council. Minto also wanted to secure better representation both of the landed and commercial interests and of Muslims in the legislative councils. Separate electorates were therefore set up. He has since been strongly criticized for this move on the ground that it alienated the Muslims from the Hindus and was part of a policy of divide and rule that led to the eventual partition of India. But leading Muslims had already expressed their fears of the consequences for the Muslim minority of the extension of representative institutions, and it can be argued that Minto was concerned to reassure them. Moreover, the policy followed his general aim of securing a fair representation of the various interests in the community. On this basis the elective system was extended and the powers of the legislative councils were increased. Besides the concession of political reforms, Minto believed in decisive action against sedition and terrorism; he revived the government's power of deportation without trial to deal with Lajpat Rai and Ajit Singh, and took fresh powers to deal with incitement to murder and the making of explosives. Such measures strained his relations with Morley. The princes formed another interest that Minto wanted to associate more closely with British rule and his general attitude toward them was more conciliatory than Curzon's.

Minto returned to England in 1910, and died at his home at Minto in Scotland on March 1, 1914.

**MINUCIUS FELIX, MARCUS** (fl. 2nd or 3rd century A.D.), one of the earliest Christian apologists (*see* APOLOGISTS, EARLY CHRISTIAN) to write in Latin, is the author of the *Octavius*, a dialogue on providence and Christianity in general (without mention of Christ's name), between the skeptic and nationalistic pagan Caecilius Natalis and the Christian Octavius Januarius, a friend of the author. The arguments are borrowed chiefly from Cicero (especially the *De natura deorum*) and the Christian material mainly from the Greek apologists. The beauty of the treatise lies in its classical refinement, not in its originality. The *Octavius* was written before Cyprian's *Quod idola dii non sunt* (*c.* 250), which borrows from it, but it is a matter of controversy whether Minucius influenced or was influenced by Tertullian's *Apologeticum* and *Ad nationes* (197). If Minucius was the earlier author, the *Octavius* was written before 197; otherwise it dates from 197–250.

Quispel, "Anima naturaliter Christiana," *Latomus*, 10:163–169 (1951); for opposite view *see* B. Axelson, *Das Prioritätsproblem Tertullian—Minucius Felix* (1941), and C. Becker, *Tertullians Apologeticum* (1954).

(G. Q.)

**MINUFIYAH, AL,** a *muhafaza* (governorate) of lower Egypt situated in the western part of the apex of the Nile Delta. It is bounded east by the Damietta branch of the Nile, north by Al Gharbiyah *muhafaza*, west by the Rosetta branch of the Nile and the Western desert, and south by Giza *muhafaza*. Area 585 sq.mi. Pop. (1960) 1,347,953. The province includes some of the most productive land of the delta and supports some of the densest populations, exceeding 2,300 per square mile in the centre. Agriculture is the principal occupation, employing 67% of the occupied population. Nearly one-third of the land is under maize, the other principal crops being cotton, wheat, and clover. Dates and bananas are the principal tree fruits. The major source of irrigation water is the Raiyah al Minufiyah, a canal that flows from the Mohammed Ali barrage and supplies the centre of the province via the Bahr Shibin and the Baquriyah Canal. There are no mineral resources. Over 90% of the population lives in villages and small towns, the principal of which are Shibin al Kawm (the capital), Minuf, and Ashmun. These are market towns, the few industries being those associated with agriculture: cotton ginning and milling.

(A. B. M.)

**MINUIT (MINNEWIT), PETER** (*c.* 1580–1638), Dutch governor of New Netherland, founder of New Amsterdam, and colonizer of New Sweden, was born of Dutch ancestry in Wesel, Rhenish Prussia, about 1580. In Holland he was appointed director-general of the Dutch West Indies company's settlements in North America in 1625. He landed on Manhattan Island on May 4, 1626. Calling the native Indian chiefs into council, he purchased from them for merchandise valued at 60 guilders (about $24) the entire island of Manhattan, which he intended to make the centre of Dutch settlement. On its southern point he built a blockhouse, warehouse, and mill, around which the early settlers of New Amsterdam made their homes (*see* NEW YORK [CITY]: *History*).

Minuit was recalled by the company in 1631. A few years later he entered Swedish service and was given command of the two vessels of Swedish and Finn colonists who in March 1638 established the first settlement upon the Delaware River, near Wilmington. There Minuit built Ft. Christina. In June 1638 he set out on a trading expedition to the West Indies, and perished in the storm in which the ship was lost. (E. E. R.)

**MINYA, AL,** a town of upper Egypt, about 140 mi. SSW of Cairo by rail, capital of the *muhafaza* (governorate) of the same name. Pop. (1962 est.) 100,000. The town, an important trading centre, stands between the Ibrahimiyah Canal and the west bank of the Nile, which there runs well to the east of its valley. West of the town the valley is eight miles wide and intensively cultivated. There are a cotton ginnery and mills for carpet and rug weaving.

AL MINYA MUHAFAZA consists of the flood plain of the Nile for about 75 mi. between Asyut governorate in the south and Bani Suwayf governorate in the north, the Eastern and Western deserts being the other boundaries. Area 878 sq.mi. Pop. (1960) 1,560,311. The *muhafaza* is heavily agricultural and has a most efficient system of perennial irrigation based upon the great Ibrahimiyah Canal, which draws its waters from above the Asyut barrage to the south. About 70% of the working population is engaged in agriculture. Principal crops (in order of importance) are cotton, corn (each occupying about one-fifth of the farmland), wheat, sugar, millet, onions, and dates. Industrial activities are limited to the processing of agricultural commodities, principally cotton ginning and flour milling. There are sugar mills at Abu Qurqas and Shaykh Fadl. Principal towns are Al Minya, Abu Qurqas, and Bani Mazar.

(A. B. M.)

**MIOCENE,** in geology, the fourth series of strata in the Tertiary system, is thus the fourth epoch in the Tertiary period of the Cenozoic era, as is shown on the accompanying geologic time chart. The name is derived from the Greek for "less recent," in contrast to the "more recent" epoch, the Pliocene (*q.v.*), which followed

During Miocene time the tropic parallels of latitude were several degrees nearer the poles than at present. Yet nipa palms no longer grew on the site of modern London as they had during the earlier Eocene epoch; the extensive Eocene tropics had already shrunken equatorward.

These climatically intermediate aspects of the Miocene were reflected also, though more indirectly so, in the animal life of the epoch. By earliest Miocene time the more grotesquely archaic browsing mammals of the older Tertiary were gone. Most modern mammal families were already represented, yet in the land faunas of the Miocene these newcomers lived side by side with still other older mammalian stocks. Among the shellfish that flourished in the Miocene seas extinct species far outnumbered species that are still found living along the seashore today.

## MIOCENE GEOGRAPHY

The Oligocene had been an epoch of increased topographic relief, crustal uplift and land emergence. In the Miocene which followed, two widespread re-expansions of the sea, early and late, were interrupted during a middle Miocene interim by localized mountain-making movements and shiftings of the shelf seas. Late Miocene time was followed by another interval (Mio-Pliocene) of crustal uplift and regression of the seas, prior to the marine transgressions of the Pliocene.

In Europe the Oligocene North sea persisted into Miocene times in Denmark (Jutland) only. Nor was the Miocene North sea as extensive as that of the Eocene or Oligocene; it covered only the fringes of eastern England (?), northern Belgium, the Netherlands and northern Germany. A probable late-Miocene connection with southeastern Europe remains undemonstrated; nor were the Eocene and Oligocene marine connections with the arctic via western Siberia re-established. Much of Britain, Fennoscandia (the Baltic shield), central Europe, Iberia and Sardinia-Corsica remained land. The Alps, Pyrenees and Carpathians were already rising. Atlantic gulfs penetrated Brittany, Touraine, Aquitaine and Portugal, and though a barrier appears to have cut it off from the North sea, the Miocene Atlantic was connected with the Mediterranean by way of Andalusian and Riffian (northwest African) straits. Italy was under deep water. A narrow foredeep extended up the Rhône and, during the disturbed middle Miocene (Styrian orogenies, deep-water Schlier deposits) stretched across northern Switzerland to the Vienna basin. Thence a late Miocene sea extended eastward over Hungary, southern Russia and Turkistan where it subsequently changed into an extensive brackish-water, then fresh-water and finally a saline inland sea, of which the Aral, Caspian and Black seas are shrunken relics. Contemporaneously, Mio-Pliocene marine bays remained in parts of Europe (north Germany, Belgium, Brittany, Italy) which by then, from Greece (Pikermi) westward, was largely above the sea. Narrow landlocked marine troughs (Sahelian, after Sahel d'Oran, Alg.) with abyssal waters existed farther southwest.

From southern Asia Minor the Miocene eastern Mediterranean extended southward to Egypt (Globigerina marls), eastward to Persia (Fars, Iran) and western India (lower Miocene Gaj formation), and to the fringes of Zanzibar, Madagascar and Ceylon. But somewhere in this Afro-Asian region—perhaps in the Mascarene Islands (Indian ocean) area—low-lying land-bridges existed intermittently. The previous marine waterway (Tethys) connecting southern Europe and southeastern Asia, beginning to break up during the Oligocene, was finally sealed off by middle Miocene times. Thenceforth (through Pliocene time), along the foot of the rising Himalayas continental sediments (Siwalik) were deposited, preserving fossil remains of primates displaying manlike characteristics.

Eastward, beyond a nonmarine upper Burma and beginning with the "Beboeloe transgression" (Upper *e* and Lower *f*) of the sea over the land (*see* Miocene Correlation chart, Indo-Pacific, Upper *e* and Lower *f*), spread an Indo-Pacific ocean. Its tropical Miocene faunas reached the Philippines, Japan, New Zealand (Hutchinsonian, Altonian), the Pacific islands and Australia (Batesfordian, Balcombian).

In western North America a provincial marine fauna evolved out of earlier Caribbean, trans-Pacific and local sources. Miocene volcanism was marked (Columbia river, south-central California); early Miocene block-faulting and breccia accumulation (San Onofre) were extensive in southern California. The Sierra Nevada, rising along its eastern fault scarp, interrupted former westward-flowing drainage from the interior, permitting the accumulation of a biogenetic formation (Monterey) in the Coast Range marine trough immediately to the west, while landlaid beds (Rosamond) were deposited east of the range. While the Gulf Coast and Atlantic seaboard were beneath a Miocene shelf-sea, the West Coast Ranges, the Caribbean, Central America and northern and western South America were often under deeper waters. But largely, the Americas remained above the sea (archipelagic California, the western interior across to Florida, parts of Venezuela, Colombia, Bolivia, "Santacruzian" Patagonia).

*Geologic Time Chart*

| System and Period | Series and Epoch | Distinctive Records of Life | Years |
|---|---|---|---|
| **CENOZOIC ERA** | | | |
| Quaternary | Recent | Modern man | 01 |
| | Pleistocene | Early man | 1,000 |
| | Pliocene | Large carnivores | |
| | Miocene | Widely open, grazing forests | |
| Tertiary | Oligocene | Large browsing mammals | |
| | Eocene | Rise of flowering plants | |
| | Paleocene | First placental mammals | 70,000 |
| **MESOZOIC ERA** | | | |
| Cretaceous | | Extinction of dinosaurs | 135,000 |
| Jurassic | | Dinosaurs, insects, primitive birds, first small mammals | 180,000 |
| Triassic | | Appearance of dinosaurs | 225,000 |
| **PALEOZOIC ERA** | | | |
| Permian | | Reptiles developed, conifers abundant | 275,000 |
| Carboniferous | | | |
| Upper (Pennsylvanian) | | First reptiles, coal forests | 350,000 |
| Lower (Mississippian) | | Sharks abundant | 415,000 |
| Devonian | | Amphibians appeared, fishes abundant | 440,000 |
| Silurian | | Earliest land plants and animals | 500,000 |
| Ordovician | | First primitive fishes | 600,000 |
| Cambrian | | Marine invertebrates | 800,000 |
| **PRECAMBRIAN TIME** | | | |
| | | Few fossils | 3,000,000–4,000,000 |

## MIOCENE LIFE

**Marine Life.**—Physically, Miocene geography approached that of the earlier Eocene, but crustal disturbances during the intervening Oligocene time had erected new barriers to marine life dispersal (isthmic links, marine deeps, shifted isotherms). At high latitudes thermal barriers adversely affected current-borne tropical life; no cosmopolitan marine fauna reappeared. Endemic evolution and provincialism became established in the sea. Although elements of Eocene and Oligocene origin are still discernible in modern faunas, the major outlines of the Recent marine invertebrate faunal provinces were determined during the Miocene.

Many invertebrate lineages previously conspicuous declined or disappeared. *Turritella*, persisting, gave ground to other suddenly expanding gastropods (Cancellariidae, Columbellidae, Nassidae, Thaididae). The cocklelike "giant venericards" (*V. planicarta*), formerly widespread, had been replaced during the Oligocene by large scallops (*Pecten*) and certain clams (*Dosinia*); the older nummulite and discocycline foraminifers by orbitoids (*Lepidocyclina, Miogypsina*) and cycloclypeids; these still abounded in the Miocene though, except for a few living relics, tropical shallow-water large foraminifers such as those mentioned suddenly disappeared after the Miocene. Oysters attained great size; offshore, small foraminifers flourished; echinoid cake urchins and sand dollars (*Clypeaster, "Scutella," Astrodapsis*) multiplied, diversified and expanded. Other stocks (diatoms, corals, cephalopods, crustacea, insects, large-toothed sharks) were locally important. Mammalian marine adaptations appeared (seals, sea lions, *Dermatylus*), or became modernized (sea cows, whales).

**Land Life.**—Land mammals were more like modern ones than before. Among carnivores the huge bear dogs, *Amphicyon* (*see* CARNIVORE, *Extinct Carnivores*) were conspicuous. Eurasian faunas included deer, hyenas and eventually the earliest giraffes and

CORRELATION CHART FOR MIOCENE AND DIRECTLY PRECEDING AND SUCCEEDING GEOLOGIC EPOCHS

bovines. Mastodonts spread into North America for the first time. There, as grasslands spread more widely, browsers were soon surpassed by grazing mammals; camels and horses evolved rapidly, horses especially spreading widely during the emergent Mio-Pliocene (*see* also Equidae). The distinctive South American mammals were still isolated on their insular continent, as were the marsupials and monotremes in Australia.

Vegetation, responding to climatic change through the Cenozoic, shifted equatorward along the north-south trending mountain ranges bordering the Pacific, except where east-west trending strandlines, or beaches, interfered (Malaysia, Caribbean). But where mountains run east-west through the old world a Miocene Mediterranean flora, trapped there, is ancestral to the modern flora upon which human agricultural civilizations first grew. *See* also Paleobotany; Paleontology.

## STRATIGRAPHY

The term Miocene was introduced by Sir Charles Lyell (*q.v.*). Derived from the Greek meaning less and recent (*see* above), it indicates that the series carries a smaller percentage of living species than found in the overlying Pliocene. The term first appeared, and apparently was first conceived, with reference to the Superga hills sequence, near Turin, Italy, as type, although other strata (Touraine, Bordeaux, Vienna) were also involved in the original studies. Lyellian correlation (by percentage of living species), supplemented locally by stratigraphically restricted (index) species, has permitted worldwide identification of the Miocene. Yet neither principle mentioned permits the refined age determinations required for correlating series boundaries or subdivisions.

Historically, in the sense of "original meaning," neither precise limits nor true subdivisions of the Miocene were involved in Lyell's definitions. Nonmarine beds, delimiting uppermost "type Oligocene" and separating "typical Miocene" from "typical Pliocene," further complicate both boundary problems; ambiguous usages have followed: Oligo-Miocene (for Aquitanian) below, Mio-Pliocene (for Sarmatio-Pontian) above. Based on degrees of biogenetic affinity (not per se indicative of time, since geological changes in environment do not affect all organismal lineages

equally), in general, invertebrate paleontology has included both transitional intervals within the Miocene; vertebrate paleontology has not.

Laterally, in correlating subdivisions (stages, zones) of the series, zoogeographic facies prevents a ready worldwide application of Albert Oppel's (*see* JURASSIC SYSTEM) zonation principle. Not in use everywhere (middle east and middle and South America) provincial stage-subdivisions of the Miocene have nevertheless come into local use in most other Miocene faunal provinces. See also PALEONTOLOGY: *Geological Paleontology*, and physical geography and geology sections of articles on continents and countries.

**MIR**, the traditional Russian rural community. As an institution of local self-government the *mir* is very old, but no documentary evidence about its activities is available before the 15th and 16th centuries. At this time the peasants in each rural district (*volost*) elected an elder (*starosta*) and other communal officials. They had jurisdiction over local forests, fisheries, hunting grounds and vacant lands; the arable lands and meadows were held by the peasant households in hereditary tenure. In the middle of the 18th century the sphere of competence of the communal officials was enlarged, and in many provinces all local judicial and administrative functions were entrusted to them. During the 17th and 18th centuries the scope of peasant self-government was restricted by appointed government officials on state domains and by the landowners on private estates. The growth of serfdom gradually deprived the peasants on private estates of their personal and property rights, and the elected officials of the *mir* became auxiliary organs of the manorial administration.

About 1720, the government imposed a heavy poll tax upon all males of the lower classes, regardless of age and economic status. To make this tax more equitable, the manorial administration and the peasants themselves felt it necessary to establish a direct relation between the size of a household and the amount of land that it possessed. This was achieved through the periodic redistribution of arable land. On state domains this system became consolidated only at the beginning of the 19th century; the competence of the *mir* in land distribution and other local affairs was recognized by law in 1838. Most Russian peasants considered redistribution a just practice and often introduced the system on their own initiative. By the end of the 19th century it prevailed in more than three-quarters of all peasant households. Only in the western (formerly Polish) provinces did private landed property predominate among the peasants.

When serfdom was abolished in 1861, the liberated peasants received considerable self-government. The members of the community formed a village assembly (*selski skhod*), which elected an elder and freely managed all internal affairs. Only in 1889 was the activity of the assembly placed under the control of an agent of the government (*zemski nachalnik*). The land was granted to the former serfs and state peasants in communal tenure, and the members of the commune were collectively responsible for the payment of state taxes and the fulfillment of local obligations.

Communal landholding promoted the sense of equality and mutual aid within the community, and the decisions of the *mir* possessed indisputable authority. But from the economic viewpoint the system was inefficient. The communal land first had to be divided into sectors, according to quality and distance from the village; each sector was then subdivided into three fields; and within each field every household received, in temporary possession, a strip of land in proportion to its size. All field work had to be completed simultaneously since after the harvest the fields were used as communal pasturage. This system hindered agricultural progress and was largely to blame for the low standard of living of the Russian peasantry.

Nevertheless, the agrarian community was highly regarded by various currents of Russian public opinion. The Slavophils and the political conservatives praised it as a guardian of the old national values. A. I. Herzen and the revolutionary Narodniki saw in the *mir* the germ of a future socialist society. The government, until the end of the 19th century, considered the rural community the pillar of a patriarchal way of life, and in fiscal affairs it preferred to deal with the *mir* rather than with a great number of individual taxpayers.

After the revolution of 1905, the prime minister P. A. Stolypin issued the law of Nov. 22 (new style; 9, old style), 1906, which gave the head of every household the right to demand the transfer of his plots into private ownership. By the end of 1914, out of a total of 9,000,000 households possessing land in communal tenure, 2,500,000 had converted their allotments into private property, and about 600,000 applications for conversion were still pending.

**MIRABEAU, HONORÉ GABRIEL RIQUETI,** COMTE DE (1749–1791), the greatest orator and probably the ablest political mind in the Constituent Assembly at the beginning of the French Revolution, was born at Bignon, near Nemours, on March 9, 1749. He was the elder son of Victor Riqueti, marquis de Mirabeau (*q.v.*), by his unhappy marriage to Marie Geneviève de Vassan.

**Early Life.**—Ugly from birth and further disfigured by smallpox at the age of three, the precocious Honoré Gabriel was soon on bad terms with his formidable father. At the age of 15 he was sent as a pupil to the strict abbé Choquard in Paris, and at 18 he went as a volunteer to serve in a cavalry regiment at Saintes, where his father hoped that military discipline would curb him. His misbehaviour, however, led to his imprisonment on the Ile de Ré, under a *lettre de cachet*. Released to serve in Corsica with the rank of sublieutenant in the army, he distinguished himself there in 1769. Returning with his father, he married a rich Provençal heiress, Émilie de Marignane, in 1772, but his heavy spending and further misconduct led his father to have him imprisoned under another *lettre de cachet* and put out of reach of his creditors. He was detained first at the Château d'If (1774), then at the Fort de Joux, near Pontarlier. Having obtained permission to visit the town of Pontarlier, he there met his "Sophie"—in fact the marquise de Monnier (Marie Thérèse de Ruffey), the young wife of a very old man. Eventually he decided to escape to Switzerland, where Sophie joined him; they then made their way to Holland, where Mirabeau was arrested in 1777. The tribunal at Pontarlier had meanwhile sentenced him to death for seduction

and abduction, but he escaped execution of the sentence by submitting to further imprisonment under a *lettre de cachet*. In the château of Vincennes, he composed the *Lettres de Vincennes* (addressed to Sophie), some erotic works and his essay *Des lettres de cachet et des prisons d'état*. Released in Dec. 1780, he finally had to surrender himself to arrest at Pontarlier in order to have the death sentence revoked; but by Aug. 1782 he was entirely free. He now became involved in a lawsuit against his wife, who wanted a judicial separation. Pleading on his own behalf, he gained the sympathy of the public but lost his case (1783). Rejected by his wife and by his father, he had to renounce the society into which he had been born.

For the next five years Mirabeau lived the life of an adventurer. He was employed sometimes as a hired pamphleteer, sometimes as a secret agent. He came into contact with the ministers Calonne, Vergennes and Montmorin (A. M. de Montmorin de Saint Hérem), made an enemy of Necker, at that time director of the finances, and engaged Beaumarchais in controversy. His activities necessitated much traveling. In London he was introduced into the best Whig society by Gilbert Elliot, who had been his fellow pupil under the abbé Choquard; he had to take refuge in Liège when his *Dénonciation de l'agiotage* (against stockjobbery) annoyed Calonne; and he undertook a secret mission to Berlin in 1786. With the active assistance of a Brunswick friend, Jacob Mauvillon, he wrote *La Monarchie prussienne sous Frédéric le Grand* (1788), which he dedicated to his father; but *L'Histoire secrète de la cour de Berlin*, in which he made unscrupulous use of material derived from his mission in Germany, created a scandal in 1789.

**The Revolution.**—When the estates-general were summoned (*see* FRANCE: *History;* FRENCH REVOLUTION), Mirabeau hoped to be elected as a deputy for the nobility of Provence. For this he needed his father's support. Pleased by the book dedicated to him, the marquis had summoned Mirabeau to Argenteuil in the autumn of 1788 but had not given him any real help. Mirabeau presented himself in the chamber of the nobility in the estates of Provence in Jan. 1789 and uttered violent diatribes against the privileged classes but was not elected deputy, as he held no fief. Turning reluctantly to the third estate, he secured election, in April, both at Marseilles and at Aix-en-Provence. He chose to represent Aix.

Unlike Sieyès, Mirabeau came to the estates-general without any precise constitutional doctrine. An avowed enemy of despotism (he had written an *Essai sur le despotisme* before he was 25), he was nevertheless a firm supporter of the monarchy and of the executive power. Without expressly adhering to the English system, he wanted representative government. A nobleman rejected by his class, he opposed the idea of an aristocratic second chamber. Like most of his contemporaries, he had no political experience, but his intelligence and his knowledge of men made him supremely capable of acquiring such experience rapidly. Lack of money, however, exposed him to pressure and to temptation.

From May to Oct. 1789, Mirabeau played a decisive part in the battle between the third estate and the privileged orders. His aim was to become the spokesman of the nation to the king and at the same time to moderate the expression of the nation's wishes. Thus on June 15 and 16 he was careful not to suggest the name "National Assembly," which was the rallying cry of the third estate in its revolutionary debate of June 17, when it set itself up as representative of the whole nation. Yet at the ending of the "royal session" of June 23, when the marquis Henri Évrard de Dreux-Brézé, in the king's name, ordered the assembled estates to return each to its separate chamber, Mirabeau's answer did much to confirm the deputies in their resolution to disobey; and in the feverish atmosphere of the early days of July he inspired the assembly's address on the dispersal of the troops concentrated round Paris. After the fall of the Bastille (July 14) he urged the assembly to demand the dismissal of the ministers who were to blame for the disorders. His popularity in Paris was then considerable. On the other hand, he disapproved of the assembly's precipitate action in abolishing feudalism (on the night of Aug. 4) and of the abstract Declaration of Rights, and while he was openly against a second chamber, he yet wanted the king to have an absolute veto. In October, when the Parisians marched on Versailles and took the king back to Paris, Mirabeau's attitude was ambiguous and gave rise to the suspicion that he might be plotting against the king—perhaps in favour of the duc d'Orléans (the future Philippe Égalité). To clear himself and to keep open the door to the court's favour, he addressed a memorandum to the king, advising him to leave Paris for Rouen, to secure the support of a small army and to appeal to the provinces.

Mirabeau's prime concern, however, was to win "the battle of the ministry." Ostensibly a supporter of Necker, he in fact did his utmost to destroy him: his brilliant speech on the bankruptcy of the nation was a masterstroke against the minister. Furthermore, he tried skilfully to induce the assembly to grant to the king the option of choosing members of it to be his ministers; but the assembly's decree of Nov. 7, 1789, precluding all deputies from the ministry for the duration of the session, frustrated his hopes of ministerial office for himself.

From Nov. 1789, notwithstanding his oratorical triumphs of Jan.–April 1790 in the cause of the Revolution (in particular his attack on the *parlement* of Rennes), Mirabeau was a prey to despondency and aimlessness until his friend Auguste de La Marck, with the approval of Florimund von Mercy d'Argenteau, Austrian ambassador to Paris and the queen's confidant, approached him with the proposal from Louis XVI and Marie Antoinette that he should become their secret counselor. Mirabeau accepted with delight: "I shall make it my chief business to see that the executive power has its place in the constitution" (letter of May 10). Part of the promised remuneration was to be the paying-off of his debts. In May 1790, when the assembly was debating the king's right to make war and peace, Mirabeau successfully opposed Antoine Barnave, whom he challenged with the words: "Tell us that there should be no king, do not tell us that there should only be a powerless, superfluous king." He impeded the progress of the Jacobins but risked his own popularity, and a pamphlet against him was circulated (*Trahison découverte du comte de Mirabeau*). From June to October he had to work to recapture his prestige. This was the more necessary because the king and the queen, despite their secret interview of July 3 with Mirabeau at St. Cloud, took little notice of his advice and continued to be influenced by Lafayette, who had scorned Mirabeau's offer of alliance. In Oct. 1790 the assembly further disappointed Mirabeau by refusing, after more discussion, to revoke the decree of Nov. 1789 on the noneligibility of its members for the ministry.

While the court was displeased by some of Mirabeau's outbursts and by his "incurable mania of running after popularity," Mirabeau for his part was enraged to see a new ministry formed under the influence of his rivals Lafayette and Alexandre, comte de Lameth. By the end of Nov. 1790 his relations with the court were severely strained. He restored them by submitting to Montmorin a "Plan" concocted for bringing pressure to bear by various means on the assembly, on Paris and on the provinces, so as to co-ordinate "the means of reconciling public opinion with the sovereign's authority." In Mercy d'Argenteau's opinion the plan was perfect in theory but very difficult to put into practice. From Jan. 1791 it was clear that Mirabeau had no intention of doing anything that might compromise his own popularity, though he was willing enough to "spike" the assembly by getting it to adopt ill-considered measures of religious persecution and was eagerly and adroitly working to discredit Lameth's faction. His popularity rose to its zenith, and the eyes of all Europe were on him. As spokesman of the diplomatic committee, on Jan. 28, 1791, he made a speech that bore the unmistakable stamp of statesmanship: anxious to avoid anything that might compromise France's relations with neighbouring countries, particularly with England, he yet would not repudiate any of the Revolution's political victories or allow any necessary military precautions to be overlooked. On the following day he at last became president of the assembly for a fortnight. In this office, from which he had been so long excluded, his control of the debates was masterly.

Mirabeau's problem was to know how and for how long his Machiavellian game could be continued without his being exposed or giving himself away. The people of Paris were restless, worried

by rumours. Mirabeau's position was made difficult by his intervention on behalf of the king's aunts, Mme Adélaïde and Mme Victoire de France, who had fled from Paris, by his hostility to the law against the *émigrés* and by his harsh words against the Lameths and their satellites in the assembly ("Silence to the factious! Silence to the 33!"). On Feb 28 he was sorely pressed to justify himself to the Jacobins after a pitiless attack by Alexandre de Lameth. The newspapers of the left redoubled their accusations of treason against him, and in March he sustained some notable reverses in the assembly. Death may have saved him from political defeat. Gravely ill since his presidency of the assembly, he worsened his condition by excessive indulgence, took to his bed on March 27 and died on April 2, 1791. The people's grief for him was boundless; he was given a magnificent funeral; and it was for him that the new church of Ste. Geneviève was converted into the Panthéon for the burial of great men. In the insurrection of Aug. 10, 1792, however, proofs of Mirabeau's relations with the court (the papers of the intendant A. de Laporte) were found in an iron chest in the Tuileries palace; and on Sept. 21, 1794, his remains were dislodged from the Panthéon by order of the Convention.

As a statesman, Mirabeau failed in his main object, that of reconciling the monarchy with the Revolution and a strong executive with national liberty: he was too much of a monarchist for the Revolution, too revolutionary for the monarchy. As an orator he was unsurpassed. Even though his eloquence was fed by material gathered from every quarter and by a "workshop" of collaborators, it was Mirabeau who found the striking images and expressions that give to his speeches their brilliant individuality. Generally bad at extemporizing, he could be moved by anger or injured pride to an impassioned tone that would carry the assembly with him. Barnave described him as "the Shakespeare of eloquence." There are editions of his speeches by E. Méjan in five volumes (1791–92) and by P. Blanchard in ten volumes (1819–22). His letters to the court are printed as *Correspondance entre le comte de Mirabeau et le comte de La Marck*, edited by A. F. de Bacourt, in three volumes (1851).

**MIRABEAU, VICTOR RIQUETI,** MARQUIS DE (1715–1789), French political economist, the forerunner and later the great patron of the Physiocratic school, was born at Pertuis in Provence on Oct. 4, 1715. He abandoned a military career, which his father wanted him to pursue, for literature. He first attracted general notice with *L'Utilité des états provinciaux* (anonymous, 1750). This marked an important stage in the movement for the reform of French local government by its radical criticism of Louis XIV's centralized bureaucracy and by its suggestion that provincial estates, which then existed only in *pays d'états*, should be set up throughout the kingdom. His prestige as a political thinker and economist was finally established by *L'Ami des hommes, ou traité de la population* (1756), which reflected the ideas of Richard Cantillon but also anticipated some of the fundamental doctrines of the Physiocrats (*see* PHYSIOCRATIC SCHOOL), especially their conception of the primacy of agriculture in economic affairs. Mirabeau then associated himself, under the influence of François Quesnay, with the Physiocrats' attempts to reform the system of taxation. In his *Théorie de l'impôt* (1760) he attacked the system of farming out the indirect taxes, recommending instead the establishment of direct taxes on land and on personal income. This led to his imprisonment at Vincennes and to his temporary exile to his estate at Bignon, near Nemours. Thereafter, despite trouble with his wife (Marie Geneviève de Vassan, whose protracted suit for judicial separation undermined his health and ruined his personal fortune) and with his son (*see* MIRABEAU, HONORÉ GABRIEL RIQUETI, Comte de), he devoted his efforts to the advancement of physiocracy. He died at Argenteuil on July 10, 1789.

**MIRACLE,** generally defined by the etymology of the word (Gr. *thaumasion*, Lat. *miraculum*) as that which causes wonder and astonishment, being extraordinary in itself and inexplicable by normal standards, or as a sign (Hebrew *'oth*, Gr. *semeion*) indicating something other than itself. Extraordinary and astonishing happenings become specifically religious phenomena when they express, reveal or signify a religious reality, however defined. This article discusses miracles mainly as seen, experienced and interpreted in the religious context, irrespective of the scientific or philosophical judgment passed on them from the outside.

**Types.**—The mythological accounts of the origins of the gods and their activities in the primeval past should not be classed as miracles, and the term is better reserved for outer events (as distinct from inner experiences, visions, etc.) regarded as divine interventions or as manifestations of divine, that is to say numinous, powers (*e.g.*, in the case of impressive natural phenomena). Man can be the object of miracles, as for instance when his disease is miraculously healed, or their subject, when he performs miracles in whatever "power" he experiences as moving him. The founders of religions are all at the centre of great miracle cycles, and miracles occur, as a rule, in connection with holy men, holy places and holy objects (relics, holy images, sacraments). Theologically, miracles serve as credentials for claimants to religious leadership or prophecy (*cf.* Ex. iv, 1–9, 30–31; Deut. xviii, 21–22), as demonstrations of the superior powers of a particular God (*e.g.*, Ex. vii, 9–12) or as evidence of the truth of a particular religion.

**Diffusion.**—The incidence of miracles is universal. Although primitive cultures lack a fully developed scientific conception of natural causality—and hence also the notion of a "supernatural" miracle—they know of extraordinary events, forces and operations. These are integrated in various ways, such as ritual, magic or shamanism, with the more "ordinary" modes of behaviour. Similarly the religions of the ancient world (*e.g.*, Babylonia and Egypt) had few formal miracles, precisely because certain kinds of divine action or cosmic operation (*e.g.*, oracles) were part of the normal order of things, even if priests and shamans did resort to deception. Ancient Indian mythology, like all mythologies, abounds in fantastic accounts of the doings of the gods, but the Upanishads and Brahmanas evince an increasing indifference to miracles. Like other forms of higher mysticism, they consider the spiritual experience of religious insight and transformation as the only "miracle" worth talking about. Nevertheless Hindu popular religion sets no bounds to the miraculous powers of ascetic yogis, and India has become the classic land of wonders. There is little room for the miraculous element in Confucianism, but Taoism has produced a rich crop of thaumaturgy and magic on all levels of Chinese folk religion. Miracles are taken for granted throughout the Old Testament: God "does wondrous things" (Ps. lxxii. 18; *cf.* Job v, 9) especially in the history of his people Israel (*e.g.*, the ten plagues of Egypt). In the Greco-Roman world miracles were not uncommon; there were miraculous cures (*e.g.*, at the sanctuary of Asclepius in Epidaurus), moving statues of gods, resurrections of the dead, virgin births and the like, though philosophical criticism too was articulate. Cicero in the *De divinatione* denied the possibility of miracles.

According to the earliest Buddhist accounts, Gautama Buddha deprecated the miraculous powers that he possessed as a matter of course, being "the greatest of all yogis," as utterly devoid of spiritual significance. Nevertheless miraculous accounts of his birth and life (and those of later Buddhist saints), as well as miracles in connection with his relics, proliferated as time went on, particularly in the Mahayana tradition. The Christian New Testament records various miracles of healing and of providing abundantly for specific human needs performed by Jesus Christ, and miracles did not cease after the New Testament period. They form part of the career, in life as well as after death, of the Christian saints,

and their occurrence continues (*e.g.*, Lourdes); duly established miracles are among the requirements for a process of canonization. (For the special problems of miracles in the Christian faith, *see* below.) Mohammed was the only great founder who renounced miracles and miraculous powers as a matter of principle—the Koran was the great miracle—but subsequent hagiography invested his life with superlatively miraculous details. Muslim popular religion, particularly under Sufi influence, abounds in miracles, pilgrimages to the tombs of wonder-working saints and the like.

**Significance.**—The paragraphs above show both the universal incidence and the reserve—in varying degrees—of the great founders (Buddha, Jesus, Mohammed) with regard to the performance of miracles. Miracles belong to the level of popular religion, which is the same everywhere and at all times. The tension between popular and "higher" religion is complicated by the fact that the representatives of higher religions often feel compelled to subscribe to the belief in miracles, even when their actual philosophy inclines them to dispense with it, simply because miracles are recounted in their hallowed scriptures or traditions. Although the paradox on which Christianity is founded (God-man, incarnation) almost logically implies certain miraculous expressions (virgin birth, resurrection), yet many modern theologians felt the need to integrate their rational criticism of miracles into their religious thought. This criticism may be religious (*e.g.*, the truly spiritual has no need of miraculous props), philosophico-scientific (*e.g.*, there are no miracles, but only as yet unexplained natural phenomena), historical and philological (the actual occurrence of miracles is said to be unproved, and the composition of the texts reporting them is critically analyzed) or psychological (reasons are advanced why people tend to believe in miracles). One suggested solution of the dilemma was the assertion that everything is a miracle (*i.e.*, the term does not describe an objective event but a subjective mode of experience). The Roman Catholic Church, on the other hand, insists not only on the factuality of miracles, as distinct from natural events, but also on the possibility of an objective determination of miraculous facts.

The prominent place of miracles in the history of religions is ultimately due to the fact that the encounter with the reality posited by religion (*i.e.*, God, the gods, the holy or sacred, the numinous, etc.) is essentially wonderful, extraordinary and transcending "normal" reality; hence the experience tends to crystallize in miraculous accounts. This basically religious pattern of experience easily combines with the primitive yearning after the miraculous, born of the human desire to master ordinary reality, with its needs, fears and sufferings, by means of a magical short cut to greater powers. Whereas some theological systems maintain that miracles both produce and confirm faith, the student of religion inclines to agree with Goethe's description of the miracle as "the dearest child of faith." (R. J. Z. W.)

**Miracles in the Bible and in Christianity.**—In the Old Testament, the phenomenon of miracle can be characterized through the concepts "sign," "portent," "wonders." In the New Testament these terms are also used, though the predominant accent falls on "signs" and on "power" or "mighty work." Such mighty works are usually exhibited through events in nature or personal existence, such as healing, which have bearing on historical and human destiny. Hence biblical miracles are not significant in themselves. While they have to do with nature, they are associated primarily with events and happenings that have a particular meaning for a community, such as the exodus from Egypt or the complex of events in the advent, life, crucifixion and resurrection of Jesus Christ. They are confirmatory signs of more fundamental events, which, while not dependent upon miracle, are themselves the matrix in which miracle is said to have occurred. The sign or pointing character of biblical miracles indicates their significance. They do not rest upon themselves. The Greco-Roman world was full of miracles. The setting or context provided the clue for distinguishing between miracles. Without the context, miracles were magic. The admonition of Jesus not to tell others of his healing activities is testimony that the community of faith was not to rest upon miracles, but rather that miracles were signs of the new reality manifest in him. The miracles surrounding the life of Jesus can be considered testimony that men believed that the anticipated Messiah or Deliverer had arrived, that the new age was manifest in the old, that the expectations were being fulfilled and that the mighty power of God was manifest. In biblical literature, miracles are signs of God's unique and redemptive visitation.

For the biblical writers a miraculous event was distinguished from other events simply by its extraordinary character. The question of the credibility of miracles—that is, whether or not they happened—had not arisen for them. That problem arose in the early church where the biblically oriented church confronted Greek thought. In the latter, miracle stories abounded and an attempt was made to distinguish between the authentic and the incredible. But the actual occurrence of miracles was not doubted. Generally, the Church Fathers accepted the biblical miracles both because they accepted the accuracy of Scripture and because these miracles usually had a setting and dignity that distinguished them from pagan or classical parallels. Moreover, the Fathers did not view nature primarily as a realm controlled by inflexible laws. For them, the natural world was one in which extraordinary happenings occurred in the midst of the ordinary course of events. Both aspects were conceived as anchored in the activity of God, though the extraordinary occurrences testified particularly to God's special and redeeming activity in the world. But the ordinary course of events was as mysterious as the extraordinary. It was no more self-evident than the extraordinary. For Augustine, the orderly or natural was also miraculous. Hence, it is important to note that while miracle stood beyond or above the order of nature as ordinarily conceived, it was not assumed that miracle stood against nature. It became possible to speak of nature and of super-nature or of the supernatural.

Until the 17th century, men might differ on what event was properly a miracle, but none denied that miracles occurred. The strides made by modern science in the period from Galileo through Newton brought the Christian community face to face with a conception of a mechanically ordered world that apparently admitted of fewer and fewer exceptions to its rigid order. As that happened, Christians were in the position of having either to abandon the traditional conception of miracle or to defend miracles against the new science. Initially, scientists and theologians alike held the view that since the order was created by God it could also be suspended by him. At that juncture, nature and super-nature became two different orders, each demanding the suspension of the other. But as natural science developed, the orderliness of nature in its vastness and complexity impressed men more than any possible exceptions to it could. Moreover, both Roman Catholics and Protestants in the 17th and 18th centuries generally believed that the drama of redemption, recorded in the biblical books, could be defended only through a firm stress upon prophecy and miracle. A vast literature on the evidences for Christianity developed in Protestantism, one of the chief pillars of which was the authenticity of Christianity on the basis of the occurrence of the miracles as recorded in Scripture. Protestants, particularly the English Puritans, were divided as to whether or not miracles still occurred. But they were agreed that they had happened in the past, and precisely as recorded in Scripture. Hence, much attention was given to the credibility of the biblical witnesses to miracles.

Those who interpreted the new science developed a philosophical outlook that excluded dimensions essential to a full, classical Christian understanding. Christians, on the other hand, largely defended the accuracy of the Scriptures as a book of knowledge with reference both to miracles and to science. Hence, an inevitable conflict resulted in which both parties made unwarranted claims. On the eve of the 19th century, the philosopher Kant and the theologian Friedrich Schleiermacher attempted to push into new directions. Schleiermacher accepted the ordered Newtonian world and maintained that miracles affected the domain of neither physics nor psychology. Miracle, he declared, was the religious name for natural event, and the more religious one was, the more would one see miracle everywhere. In effect, Schleiermacher had identified miracle and a religious understanding of

any aspect of the world. The distinctiveness of miracle had disappeared. But this was more the product of Schleiermacher's defective Christian understanding than it was of his particular view of miracles. Aspects of the latter view, set into another context, may indeed be feasible. Liberal Protestantism generally abandoned the traditional view of miracles and stressed the evidences for Christianity in a different form, namely the transformation of the moral and religious lives of people.

In the early decades of the 20th century the character of both science and Protestant theology changed drastically. The rigid conception of order in the atomic levels of physics had been severely challenged. Regardless of what this new situation meant in physics, it brought a new tentativeness into science and undermined the philosophical views of the world allegedly extrapolated from a rigidly ordered conception. At the same time, the change in Protestant theology brought about a fresh appreciation of the biblical dimensions in their own terms. In that development, the reality attested to through biblical miracles was again more central than the miracles themselves, as it had been in the early church and in the Reformation. Some interpreted the change in science as warranting the acceptance of the biblical miracles as recorded. But that view was probably a misinterpretation both of science and of Scripture.

Since the early decades of the 20th century, Protestants generally have accepted the concept of miracles as standing for dimensions of reality in which God's directing presence is encountered in the intensity of redemptive deliverance. But such happenings are understood as not directly discernible on the level of nature. Roman Catholics, on the other hand, have generally accepted miracle in the more traditional sense of impingement upon the domain of nature. (J. Di.)

**MIRACLE PLAY:** *see* Drama: *Medieval Drama.*

**MIRA DE AMESCUA, ANTONIO** (1574?–1644), Spanish dramatist and author of one of the most powerful of Spanish religious plays, *El esclavo del demonio* (before 1613), was born at Guadix, where he returned as archdeacon after many years at Granada, Naples and Madrid. His masterpiece, based on the Faustian legend of the 13th-century Portuguese St. Aegidius, treats the favourite Spanish antitheses of reality versus appearance and free will versus compulsion, displaying curious insights into the psychopathology of guilt. Among the imitators of Mira's highly original plots are Calderón, Agustín Moreto, Pierre Corneille and Jean de Rotrou.

**MIRAGE,** any of a number of different kinds of atmospheric optical illusion in which the observer sees nonexistent bodies of water, oversize or inverted images of distant objects and various other distortions. A mirage is formed by the refraction, or change in the direction of travel, of light on its passage through an atmosphere having an unusual distribution of air density (*see* Refraction). An increase in density of the air decreases the velocity of light passing through it; thus as the light goes through a layer, or stratum, of marked density change, its wave front is refracted and a displaced image is likely to appear.

**Inferior Mirage.**—This phenomenon, very common in desert regions on calm, clear summer days when the surface of the ground is strongly heated, gives the appearance of an extensive horizontal reflecting surface below the level of the observer's eyes. Often, low-lying distant objects are mirrored. The observer unfamiliar with this illusion instinctively attributes it to reflection by the surface of a lake or other body of water whose wave-lapped shore is only a mile or so distant. But it is a curious body of water, ebbing as far and as fast as the observer may approach it and similarly following him if he should retreat from it, and completely hiding everything below its apparent surface. Distant hills rising from a flat plain often appear as if they were islands or promontories.

Normally, in the atmosphere the density decreases steadily with height. This type of mirage occurs when, owing to the excessive heating of the ground, the density increases upward for the first 20 ft. or more, then decreases in the normal manner above that height. Under this circumstance, light originating along the horizon follows a curved path upward over the observer's head and the light which comes to him horizontally when he is above the level of maximum density also originates above that level. Distant objects may be of such a height that their upper part is seen from a path of light that goes deep downward convexly toward the earth and their lower part from a less deep path, thus producing the inverted effect of a mirrored image.

*Road and Street Mirage.*—This illusion of people, perhaps splashing unconcernedly through puddles and streams, is a miniature inferior mirage.

*Lateral Mirage.*—On close observation it is sometimes possible to see along a strongly heated, vertical wall a mirage of the same origin and having the same explanation as that so common along roads.

**Superior Mirage.**—A superior mirage is the simultaneous appearance in the low sky of a distant low object in the form of two images, one above the other, the lower one being inverted while the upper is not. This occurs under certain conditions, especially over cold waters when the lower air is very much colder and therefore denser than the air immediately above it. In this case the apparent mirror surface is above the observer at the level where the density exhibits a sharp decrease with height.

**Fata Morgana.**—This is the inferior-superior double mirage, involving a combination of the two types of density distribution described above. Under perfect conditions objects such as cliffs or a distant, simple cottage look like a wondrous castle, half up in the air, half down in the sea.

It is of rare occurrence, though well known, especially in the Strait of Messina between Italy and Sicily, where it received its name from its fancied reflection of a submarine palace of Fata Morgana (*q.v.*), or Morgan le Fay. It has also been seen over Toyama bay on the western coast of Japan and is sometimes observed over the Great Lakes in North America.

For explanatory diagrams, illustrations and references, *see* W. J. Humphreys, *Physics of the Air* (1940). (W. J. Hu.)

**MIRAMÓN, MIGUEL** (1832–1867), Mexican soldier, president and marshal of Maximilian's empire, was born in Mexico City on Sept. 29, 1832. He fought against the United States in 1847. In 1856 he helped establish Félix Zuloaga as Conservative president in opposition to the Liberals led by Benito Juárez. In the bitter Three Years' War which followed he led the Conservative forces and finally succeeded Zuloaga as president only to be overthrown by the victorious Liberals in Dec. 1860. He took refuge in Cuba and then went to Europe. Following various maneuvers he offered his services to Napoleon III and re-entered Mexico as a grand marshal of Maximilian's empire. He served as Mexican minister in Berlin (1864–66), but returned home and again entered the army to bolster the tottering throne. Defeated by Juárez, he fell back to defend the remnant of the court at Querétaro. After the capture of that city in May, he was taken prisoner and executed there with his emperor on June 19, 1867. (W. H. Ca.)

**MIRANDA, FRANCISCO** (c. 1750–1816), Venezuelan revolutionist, belongs to the generation of men who paved the way for independence in South and Central American nations. In the history of the hemisphere his title is "el precursor," the forerunner. Born and educated in Caracas, at the age of 21 he sailed for Europe to enter the Spanish army. During this journey he began to keep a diary, a habit which remained with him to his last days, and the bulk of which forms the 15 volumes of his *Archivo*. His career in the Spanish army was not a success; he was charged with disobedience and sent to prison. In 1780, however, he was released and sent to Cuba to participate in the Spanish fight against Great Britain. There he was accused of misuse of funds. Protest-

ing his innocence, Miranda fled to the United States, arriving in June 1783.

This event was the turning point of his life. He became a rebel and an adventurer whose aim was to gain partisans and supporters for the liberation of South and Central America from the yoke of Spain. In the United States he met and became the friend of Washington, Paine, Hamilton and others. Hounded by Spanish agents, he went to London, and from there to Germany, Austria, Italy, Turkey and, finally, to Russia, where Catherine the Great showered him with her favours. Miranda's personality matured during these travels. He became proficient in languages, speaking three and reading four others. He was impulsive, opinionated, authoritarian and aggressive.

The French Revolution gave him the first opportunity to advance his revolutionary aims. To William Pitt he outlined a plan for an independent empire stretching from the Mississippi to Cape Horn, under the leadership of a hereditary emperor, called Inca, with a law-giving body of two houses. When the English prime minister showed no interest in his projects, Miranda joined the revolutionary forces of France (1792). He had not changed his goal, only the means to reach it. He fought with distinction for the Revolution, surviving terror and accusation. By 1798 he was once more in England. He tried desperately to convince the British that an attack on the Spanish colonies would be to their advantage, but in 1805 when he realized that his words fell on deaf ears, he set out to liberate Venezuela singlehandedly. The Spaniards, however, aware of his plans, were ready for him. He was twice repulsed and returned to England.

Miranda's last opportunity came in 1810. At that time Venezuela was in rebellion against Spain and Simón Bolívar had been sent to London to secure British support for the nascent state. The two men met and Bolívar persuaded Miranda to return to Caracas. He was made a general, and when the young republic proclaimed its independence on July 5, 1811, he became its dictator. But the Spanish counterattack showed Miranda weak and vacillating. Rather than make Venezuela the scene of a long and bloody war, he surrendered and signed an armistice that other revolutionaries denounced as treasonable. His attempts to escape were thwarted by his compatriots under the leadership of Bolívar. He was thrown into prison and eventually handed over to the Spaniards, who considered him still "a very dangerous man." His ankles in chains, he was transported to the Prison of the Four Towers in Cádiz, where he died in 1816.

Miranda's master plan, the liberation of the Spanish colonies with the help of the great powers, had miscarried, and his own action ended in catastrophe. His failure was the result of a personal ambition to which his abilities could not rise. Orator, general, schemer and organizer, he lacked the relentless drive that the revolutionary must have if he hopes to succeed. Miranda was a man of the 18th century. He believed in a world that daily apprehended more fully the dignity of mankind. His all too human private life also derived its character from the century; his many love affairs were pursued with the sensual energy of a Casanova. He is reminiscent at times of his contemporary, Mirabeau. Energetic, epicurean, dynamic, unscrupulous, identifying a great cause with his own personality, he seemed to have all the talents save the ability to put them to good use. Although temporary failures and frustrated ambition may dim his reputation, he is marked by greatness of purpose and by his unquenchable belief in the freedom of man.

BIBLIOGRAPHY—Vicente Dávila (ed.), *Archivo del General Miranda*, 15 vol. (1929); W. S. Robertson, *The Life of Miranda*, 2 vol. (1929); J. F. Thorning, *Miranda: World Citizen* (1952). (G. S. M.)

**MIRANDA,** a state of Venezuela on the Caribbean sea, lies east of the state of Aragua and southeast of the Federal District. Area 3,070 sq mi. Pop. (1961) 492,349. The coastal range there reaches its highest elevation. Embracing parts of both agricultural and pastoral Venezuela, Miranda ranks among the leading states, being a producer of bananas, cacao, corn, coconuts, coffee, sugar cane and yuca. The mineral possibilities are little known and have been only slightly exploited. Sugar milling and saw milling are relatively important. The state benefits by proximity to the Federal District, particularly to Caracas. It is well served by highways. The capital, Los Teques (pop. [1961] 34,874) lies southwest of Caracas on the main hard-surfaced highway to the important cities to the west—Maracay, Valencia, Barquisimeto and others. (L. We.)

**MIRBEAU, OCTAVE HENRI MARIE** (1850–1917), French writer of harshly satirical novels and plays, and one of the ten original members of the Académie Goncourt, founded in 1903 (*see* GONCOURT). He was born at Trevières (Calvados), on Feb. 16, 1850, and was educated at a Jesuit school at Vannes. After journalism in Bonapartist and royalist newspapers, he fell a prey to his native pessimism, both as a novelist and a playwright. He made his mark as a *conteur* with tales of the Norman peasantry, *Lettres de ma chaumière* (1886) and *Le Calvaire* (1887), a chapter of which on the defeat of 1870 aroused much rancour. They were followed by *L'Abbé Jules* (1888), the story of a mad priest, and *Sebastien Roch* (1890), a merciless picture of the Jesuit school he had attended. Henceforward all his novels were bitter social satires, from *Le jardin des supplices* (1899) and *Les Mémoires d'une femme de chambre* (1901) to *La 628-E8* (1907) and *Dingo* (1913). His dramatic work was of a finer quality and *Les Mauvais Bergers* (1897) was compared with the work of Henry Becque (*q.v.*). He achieved his greatest success as a playwright with *Les affaires sont les affaires* (1903), his portrait of a modern Turcaret (the hero of Le Sage's comedy). He died in Paris on Feb. 16, 1917.

(Re. L.)

**MIRFIELD,** an urban district in the Dewsbury parliamentary division of the West Riding of Yorkshire, Eng., 10½ mi. E.S.E. of Halifax and 8¼ mi. W. of Wakefield by road. Pop. (1961) 12,289. It is on the river Calder and is served by the Calder canal.

The principal industries are carpet and blanket manufacturing, cotton spinning, light engineering, coal mining and chemicals; it is a railway centre. A theological college is attached to the Home of the Community of the Resurrection, a clerical fraternity, founded by Charles Gore (*q.v.*).

**MIRFIELD FATHERS,** as the Anglican COMMUNITY OF THE RESURRECTION is known, were founded in Oxford, Eng., by Charles Gore (*q.v.*) in 1892. The members are celibate priests and laymen living under a common rule, and their work is pastoral and evangelistic, literary and educational. The community's first two superiors, Gore, philosopher and theologian, and Walter Frere, historian and liturgist, both became bishops. Among its scholars were J. N. Figgis and L. S. Thornton. In 1898 the community moved its headquarters to Mirfield, Yorkshire, where a theological college was set up for young men who, for lack of private means, were debarred from priesthood. In 1955 the community founded a theological college in Barbados, and it carries out extensive missionary and educational work in South Africa. Its concern with the social implications of Christian faith is expressed in its attitude to race relations as illustrated by Trevor Huddleston, who, during his service as provincial of the order in South Africa (1949–55), was a constant opponent of apartheid and worker for the improvement of conditions among Africans.

**MIRIM, LAKE** (Portuguese, LAGOA MIRIM; Spanish, LAGUNA MERÍN), on the border between Brazil and Uruguay, covers about 1,542 sq mi., and is 118 mi. long and as much as 30 mi. wide at its widest point. The lake drains through the São Gonçalo canal to Lagôa dos Patos.

It is a typical coastal lagoon, separated from the ocean by a sand bar about 10 to 35 mi. wide, on which there are numerous smaller lagoons and marshes. It is navigable for small lake boats. The international boundary between Brazil and Uruguay crosses the southern part of the lake from the mouth of the Rio Jaguarão to the southern end west of Chuí. (P. E. J.)

**MIR JAFAR** (MIR MOHAMMED JAFAR ALI KHAN) (d. 1765), first ruler of Bengal under English influence, was of obscure origin. His father was an Arab, Sayyid Ahmad Najafi. First heard of in Bengal in 1734, he attached himself to Ali Vardi Khan, and when that general seized the government of Bengal in 1740, became his principal military officer. Mir Jafar was an able soldier but lacked decision of character and became indolent in old age. Discontented

under Ali Vardi's grandson, Siraj-ud-Daula, who succeeded in 1756, he aspired to the Bengal government with the support of Robert Clive and the English East India company. Mir Jafar was irresolute at the battle of Plassey (1757) and thereafter was embarrassed in fulfilling his financial promises to the English, the treasure at the capital proving smaller than expected. His payments, public and private, and the concession of free passes (*dastaks*) for the English merchants' private trade, started the ruin of Bengal and the demoralization of the company's servants that marked the early years of British rule. After Clive's departure in 1760 he was deposed in favour of Mir Kasim. He was restored in 1763 and died on Feb. 5, 1765, allegedly aged 74. *See* INDIA-PAKISTAN, SUBCONTINENT OF: *History*.

(T. G. P. S.)

**MIRKHOND** (MIRKHWAND; MOHAMMED IBN KHWANDSHAH IBN MAHMUD) (1433–1498), Persian historian, author of the voluminous and famous *Rauzat-us-Safa*, belonged to an old family of sayyids (descendants of the Prophet), established in Bukhara. His father lived in Balkh (northern Afghanistan). Mirkhond spent most of his life in Herat, where he enjoyed the protection of Mir 'Ali Shir Nava'i, a celebrated patron of literature, who acted as minister to the last Timurid ruler of Herat, Sultan Husain Baiqara (1468–1506), and was himself a writer of great distinction. He died at Herat on June 22, 1498. It was at Mir 'Ali Shir's request that Mirkhond began about 1474 his general history, *Rauzat-us-Safa*, which comprises seven large volumes and a geographical appendix, sometimes considered as the eighth volume. The seventh book (on the reign of Sultan Husain and some later events down to 1523) must have been added by Mirkhond's grandson Khwandamir (Khondamir), whose *Khulasat al-akhbar* is, moreover, merely an abridgement of his grandfather's *Rauzat*. In the 19th century Riza Quli Khan (1800–72) wrote a supplement to the *Rauzat* in eight volumes.

Although he did not examine his sources critically and wrote in a florid and bombastic style, Mirkhond was for a long time the chief source of information on the history of the Persian dynasties, and European scholars published separate chapters of his work accompanied by their commentaries. In modern times, when many of Mirkhond's sources have been published in the original, his summaries have lost their importance, except for Books v and vi which contain the history of the Mongols and Timurids and give much independent and valuable information.

BIBLIOGRAPHY.—For an account of the numerous editions and translations of Mirkhond's work *see* H. M. Elliott, *History of India*, vol. iv, pp. 127–140 (1867); C. A. Storey, *Persian Literature*, ii/1, pp. 92–101 (1935) and i/2, pp. 1236–37 (1953). *See* also E. G. Browne, *A History of Persian Literature Under Tartar Dominion* (1920); V. V. Bartol'd, *Turkestan Down to the Mongol Invasion*, 2nd ed. (1928). (V. F. M.)

**MIRÓ, GABRIEL** (1879–1930), Spanish writer, distinguished for the finely wrought, sensual style of his essays, stories and novels, stands apart, in his preoccupations, from his contemporaries known as the generation of '98. Born in Alicante on July 28, 1879, he studied law at the universities of Granada and Valencia, afterward holding various small sinecures. He was hired to edit a religious encyclopaedia in 1914, but the enterprise failed in the following year. In 1922 he became secretary of the Concursos Nacionales de Bellas Artes in Madrid, where he died on May 27, 1930.

Through the creation of a literary alter ego, the character Sigüenza, Miró first found the means of releasing his artistic energies in *Del vivir* (1904), the theme of which, man cut off from God and other men, underlies all his works, notably *Corpus* (1905), *Nómada* (1908), *Figuras de la Pasión del Señor* (1916–1917), *Libro de Sigüenza* (1917), *Nuestro Padre San Daniel* (1921), *El obispo leproso* (1926) and *Años y leguas* (1928). Miró's difficult style permits maximum fidelity to his particular experience of reality through the use of a rich vocabulary, the excision of merely informative verbal tissue, the exploitation of peculiarly Spanish grammatical devices, and the manipulation of chronology so as to deny time and enhance sensorial and qualitative values in an atmosphere of pathos, comedy, irony and wonder.

**MIRÓ, JOAN** (1893– ), Catalan painter, one of the foremost exponents of 20th-century art, was born in Barcelona on April 20, 1893. He began drawing at the Lonja in his native city, where he was taught by Modesto Urgell. Miró made his first visit to Paris in 1919. Thereafter he lived in that city, in Barcelona and at his farm in Majorca. His first manner is characterized by an *avant-garde* and antiacademic attitude, with highly stylized and rounded forms. Between 1916 and 1923, however, he began to allow a certain representational element in his paintings, which at the same time are distinguished by an unmistakably passionate use of simple and violent colour; "La Masia" (1921–22) is an important picture of this period.

From 1923 onward Miró discarded the representational element more and more and got free of it through colour and through creating simple and extremely effective forms. His colours are pure, sometimes primary colours only; his line is based mainly on the curve. Influenced by André Breton's doctrines, Miró shows a strong sense of humour, which gives him his special place among the surrealists. "Dutch Interior" (1928) is one of the outstanding examples of the art of his time. From 1930 his work became even less representational, as he substituted outline drawings and schematic figures reminiscent of children's drawings or the art of primitive peoples. His feeling for decoration and contrasting masses of strong colour are dominant features of his work. As well as easel-paintings and murals, Miró did sculpture and engraving and also illustrated books and painted on pottery. (J. GL.)

**MIRROR.** A mirror can be considered as an optical instrument that produces images of objects by reflection.

## HISTORY

The earliest mirrors of the Etruscans, Greeks and Romans usually consisted of a thin disk of metal, generally bronze, slightly convex and polished on one side, the other being left plain or having a design incised upon it. Mirrors made from glass coated with tin or silver are mentioned by Pliny as having been made at Sidon, but they appear to have been little used.

Greek mirrors dating from shortly before 400 B.C. have been found. They were usually provided with a handle, which sometimes took the form of a statuette, often of Aphrodite, or consisted of two metallic disks fitting into each other and sometimes fastened together with a hinge.

Small metallic mirrors with highly polished surfaces were largely used during the early centuries of the Christian era, pocket mirrors or small hand mirrors carried at the girdle being indispensable adjuncts to ladies' dress. In 625 Pope Boniface V sent Queen Aethelberg of Northumbria a present of a silver mirror, and in early Anglo-Saxon times mirrors were well known in England.

The method of backing glass with thin sheets of metal for mirrors was known in the middle ages, at a time when steel and silver mirrors were almost exclusively used. A guild of glass-mirror makers existed in Nürnberg in 1373, and small convex mirrors were commonly made in southern Germany before the beginning of the 16th century. It was in Venice, however, that the making of glass mirrors on a commercial scale was first developed. In 1564 the mirror makers of Venice formed themselves into a corporation, and their glass mir-

EGYPTIAN MIRROR OF BRONZE DATING FROM 1900 B.C. THE HANDLE OF THE MIRROR BEARS A SCULPTURED LIKENESS OF THE GODDESS HATHOR, FIGURED WITH THE HORNS AND EARS OF A COW AND THE FACE OF A WOMAN

rors quickly supplanted those of polished metal. The coated glass mirrors were made from blown cylinders of glass, which were slit, flattened on a stone, carefully polished, the edges frequently bevelled and the backs silvered by an amalgam of tin and mercury. A sheet of tin foil was laid on a horizontal blanket lying on a flat surface; then clean mercury was spread on the foil, a sheet of paper being laid over the mercury. The sheet of very clean glass was allowed to fall slowly on the paper and the paper drawn off just as the glass reached the mercury, so that a clean surface of the mercury came into contact with the glass. Heavy weights were then laid on the back of the glass and the whole was left for the excess of mercury to be squeezed out, after which the amalgam of tin and mercury adhered to the glass.

These mirrors had a high reflecting power. The glass was remarkably pure and uniform, the silvering bright and the sheets sometimes of considerable dimensions. In the inventory of the effects of the French minister Colbert, a Venetian mirror, 46 in. by 29 in., in a silver frame, was valued at 8,016 livres, while a picture by Raphael was put down at 3,000 livres.

A considerable improvement came in France in 1691 when the art of making plate glass was introduced. The chemical process of coating a glass surface with metallic silver, now called silvering, was discovered by Justus von Liebig (*q.v.*) in 1835 and was put into practice five years later. *See* also FRAME DESIGN.

## REFLECTION BY MIRRORS

A mirror is usually associated with the reflection of visible light, though there are also mirrors for the reflection of sound, radio waves, etc. The human eye can receive light directly from an incandescent source or by scattering or reflection of the light from some source. This page scatters or diffusely reflects the light incident on it, some of which may enter the human eye. A mirror, made from a highly polished metal or a smooth surface of glass coated with silver, reflects the light in a definite manner called regular or specular reflection. The surface of a mirror must be smooth or have irregularities that are small compared with the wave length of the light being reflected. For visible light the wave lengths associated with the different colours are of the order of $\frac{1}{10000}$ in., while sound waves have wave lengths of the order of a few feet and low-frequency radio waves of the order of fractions of a mile. Thus a surface that can act as a mirror and regularly reflect sound waves can be so rough as to be of no value for reflecting visible light waves. When light falls on a body some of the light may be reflected, some absorbed and some transmitted through the body. In order for a smooth surface to act as a mirror for visible light, its surface must be bright so as to reflect as much of the light as possible and transmit and absorb as little as possible.

**Law of Reflection.**—Let us consider the reflection of light from a smooth and highly reflecting flat surface such as MM′, fig. 1. An eye at E receives light from a source S by the paths SA and AE, SA being the incident ray and AE the reflected ray. Actually the eye receives more than a single ray of light from the source. The pupil of the human eye is about three millimetres in diameter, so it can receive a bundle or cone of rays. For simplicity we shall consider a single ray that does not invalidate the result. If the lines SA, AE are drawn and a line AN is drawn at right angles or normal to the mirror, then it is found that the angle $i$ made by the incident ray with the normal is equal to the angle $r$ made by the reflected ray with the normal. Thus the fundamental law of reflection by a mirror is that the angle of incidence $i$ is equal to the angle of reflection $r$.

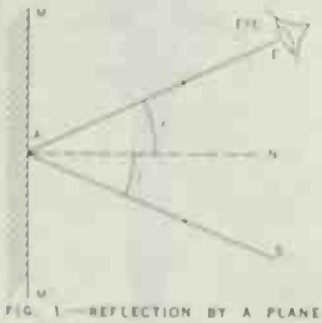

FIG. 1.—REFLECTION BY A PLANE MIRROR

Fig. 2 shows two rays forming the boundaries of the cone of light that the eye can receive. The two incident rays SA, SA′ are reflected along AE and A′E′ respectively so that their angles of reflection are equal to their angles of incidence. If the two reflected rays are projected backward they intersect at I, the image of the source S; that is, at a point as far behind the mirror as the source S is in front. The position of I can be found experimentally by placing behind the mirror a tall pin, the top of which can be seen over the mirror, and using as the source S a smaller pin. The pin behind the mirror is then moved around until it coincides with the image of S seen in the mirror, and thus directly it can be shown that the image of an object seen in a plane mirror is as far behind the mirror as the object is in front. Notice that the image I is never actually formed, or the rays of light do not actually pass through I. For this reason the image I is said to be a virtual image. That the image I is as far behind the mirror as the object is in front can be proved geometrically from the fundamental law of reflection.

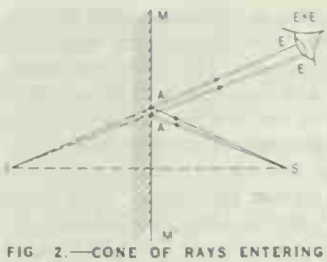

FIG. 2.—CONE OF RAYS ENTERING THE EYE APPEARING TO COME FROM IMAGE I

As shown in fig. 3, a plane mirror gives an image that is the reversal of the object. Consider the object OO′ with a projection, which is on the left-hand side when the object is viewed directly. This projection appears on the right-hand side of the image II′ seen by the eye. When a printed page is viewed in a mirror this reversal can be seen.

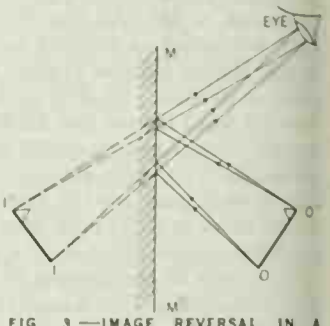

FIG. 3.—IMAGE REVERSAL IN A PLANE MIRROR

By using a combination of two plane mirrors set at right angles to one another, this reversal can be eliminated. An object OO′ is placed in front of the two mirrors shown in fig. 4. On looking into the mirrors three images can be seen. The images $I_1I_1'$, $I_2I_2'$ are produced by reflection in one mirror and show the reversal, while the image $I_3I_3'$ is produced after reflection in both mirrors and there is no reversal. The rays producing these reflections can be readily drawn. If the mirrors are set at 60° with one another, then five images may be seen, a result that can be generalized easily.

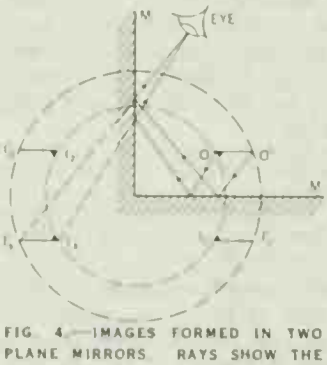

FIG. 4.—IMAGES FORMED IN TWO PLANE MIRRORS. RAYS SHOW THE IMAGE FORMED BY TWO REFLECTIONS

An interesting result follows when three mirrors are set up so that they are mutually perpendicular to each other and meet to form the apex of a tetrahedron. On looking into such a mirror system each eye sees itself in a line, and no change seems to take place when either eye is closed. This mirror system returns a beam of light from any direction back in exactly the same direction from which it came. In order to show this, consider a sphere whose centre O is at the apex of the mirrors. As shown in fig. 5, three mutually perpendicular lines are drawn, Ox, Oy and Oz, which intersect the sphere at $x$, $y$ and $z$. The three mirrors lie in the $xOz$, $xOy$ and $yOz$ planes and intersect the sphere in the great circles $yz$, $zx$ and $xy$.

Let a beam of light parallel to PO fall on the mirrors. This beam strikes the mirror $zOy$, is reflected onto the mirror $yOx$ and is again reflected so as to fall on the mirror $zOx$ from which it is again

FIG. 5.—SPHERE WITH THREE MUTUALLY PERPENDICULAR MIRRORS (xOz, xOy AND yOz) HAVING THEIR VERTEX AT O THE CENTRE OF THE SPHERE

reflected so that it comes from this mirror parallel to the direction of the incident beam PO. Draw a great circle through xP (point P is considered to be on this great circle). This meets the mirror zOy in M. Continue this great circle to P′ of such a length that MP′ is equal to MP. From the construction it follows that the angles OMP and xOM are right angles. For the ray of light parallel to PO, incident on the mirror zOy, its angle of incidence is xOP. Since MP is equal to MP′ and PO is equal to P′O, it follows that the angles POM, P′OM are equal. Thus the incident ray PO is reflected along the direction P′O. It can be shown easily that the angle P′Ox, which the reflected ray makes with the normal Ox, is the supplement of the angle of incidence POx, that is, angle P′Ox is equal to 180° minus angle POx. Reflection in any mirror changes the angle with its normal into its supplement. Successive reflections in all three mirrors will change all the angles made by OP with the normals Ox, Oy, Oz into their supplements.

Now the sum of the squares of the cosines of the angles made by PO with the normals Ox, Oy, Oz is equal to unity. Since the square of the cosine of any angle is equal to the square of the cosine of its supplement, it follows that the sum of the squares of the supplements of the angles made by PO with Ox, Oy, Oz is also unity. Thus the beam of light PO, after reflection in all three mirrors, will return exactly parallel to its incident path. The three mirrors have to be set at right angles to each other with a high degree of precision if the final image is to be single. As the final direction of the beam is simply the opposite of the original direction, it is not affected by rocking the system of mirrors.

Small tetrahedral mirrors are used as reflectors for illuminating roadside signs from the headlights of automobiles at night. The back reflecting surface of these small reflector buttons generally consists of a series of little pits, each one of which is roughly a tetrahedral apex with three perpendicular plane surfaces. Such buttons shine brilliantly when illuminated by the headlights of approaching vehicles, and the intensity of the reflected beam does not vary greatly as the angle of illumination changes.

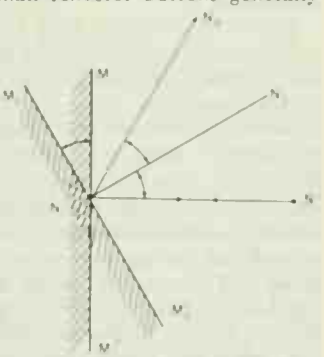

FIG. 6.—ROTATION OF A MIRROR THROUGH A GIVEN ANGLE ROTATES THE REFLECTED BEAM THROUGH TWICE THAT ANGLE

**Effect of Rotation.**—If a beam of light is reflected from a plane mirror as the mirror is rotated through some angle, then the reflected beam is rotated through twice the angle. For simplicity consider a ray of light (fig. 6) that falls perpendicularly on the mirror MM′; that is, the ray is along the normal NN′. Since the angle of incidence is zero, the angle of reflection is also zero and the reflected ray is along NN′. Now rotate the mirror to the position $M_1M_1'$ through the angle $M_1NM$. The incident ray is still N′N while the reflected ray is now $NN_2$. The normal to $M_1M_1'$ is $NN_1$, so that the angle $N'NN_1$ is equal to the angle $M_1NM$ and the angle of incidence of the ray is now $N'NN_1$. This angle is equal to the angle of reflection $N_1NN_2$ where $NN_2$ is the reflected ray. Turning the mirror through the angle $M_1NM$ results in the reflected ray's being turned through twice this angle or through the angle $N'NN_2$.

*See also* LIGHT; OPTICS. (R. J. Sx.)

## ASTRONOMICAL MIRRORS

**Early.**—During nearly two centuries, from 1668 when Sir Isaac Newton made the first reflecting telescope until the advent of the silvered-glass mirror in 1856, astronomical mirrors were thick, solid disks of a white alloy of copper with proportions of tin usually between 25% and 33.4%, on which the concave curvatures required for reflecting the light rays to a focus were ground with emery grains, and polished and finally figured, or precisely shaped, with optician's rouge. These speculum metal mirror disks were difficult to cast, brittle and hard to work, and when finished did not reflect a high percentage of light. Their chief fault was that when they became tarnished the necessary repolishing destroyed their figure, which then had to be wholly recreated. This not only forced the astronomer to acquire as much skill as the expert who figured the mirror, but interrupted his observing for days or weeks. A means whereby tarnished telescope mirrors could be replaced easily and quickly, without affecting their figure, therefore would have been a boon.

**Modern.**—Such a means arrived in 1856 when Karl August von Steinheil developed a method of coating glass telescope disks with suitable reflecting films of silver which, when tarnished and without altering the figured glass, could be removed in seconds with acid and replaced in minutes with brilliant new films by a chemical process. The mirror proper, the reflecting part, now became a film of silver about $\frac{1}{250\,000}$ in. thick; but since such films take their shape from the permanently figured glass to which they adhere and which acts as their rigid support, and also since the creation of the figure on this glass requires much more time than applying the silver film, when telescope makers use the word mirror, they refer mainly to the glass and its figure, of which the film on its surface is a replica.

Quite logically a question is often asked: since glass mirrors, the familiar looking glasses silvered with tin and mercury, were in use long before telescopes, why did astronomers ever use mirrors of speculum metal with all their drawbacks? The answer is because it was essential, as it still is, that the reflecting coating be on the front of the glass and not on the back, since front-surface mirrors obviate losses of light within the glass and at the surface, as well as spurious reflections and aberrations. But the old tin and mercury method of silvering gave only a dull, irregular surface on the front, though modern methods give excellent surfaces.

Most reflecting telescopes have solid mirror disks of glass, about one-eighth or one-sixth as thick as wide, so that the glass from its own weight will not sag the few millionths of an inch that is sufficient to alter the figure temporarily while the telescope is inclined in different positions. Another source of altered figure is the slight temporary warping of the disk caused by unequal expansion or contraction between surface and interior while it is being warmed or cooled by the surrounding air. On the mirrors of crown glass, similar in composition to plate glass, made before the 1930s, this had an effect several times greater than on the low-expansion Pyrex that came into use for mirrors at about that time. The warping caused by transient air-temperature changes was still further reduced in the Pyrex mirror of the world's largest telescope on Palomar mountain, in California, which is 2 ft. thick, nearly 17 ft. in diameter and contains a 30 000-lb. mass of glass. The reduction was accomplished by honeycombing the back of the disk with deep openings to the air. This leaves only a relatively thin front surface and behind it a grid of ribs or partitions, cast integrally and in most places only about four inches thick. Few points within the glass lie more than two inches from the surrounding air, and temperatures that in large solid disks require several hours for equalization are equalized rapidly. The ribbed construction also provides maximum stiffness with a minimum of weight.

The common belief that astronomical mirrors are made of costly optical glass, as are good lenses, is erroneous; there is no necessity for this since astronomical mirror disks are not called upon to transmit light but only to support the film of metal that reflects it. Calling an astronomical mirror a lens is also a common error.

The concave curve in the face of an astronomical mirror is seldom more than one inch in depth even in fairly large telescopes and is less than four inches in the 200-in. telescope on Palomar mountain. The disk is laid flat on a slowly rotating turntable and ground with loose, wet, abrasive grains of sugarlike size beneath a slightly convex disk of metal attached to the lower end of a power-driven vertical shaft. This tool, resembling an inverted mushroom and perhaps one-quarter of one-half the diameter of the mirror, is made to rotate slowly, while a third component is added when lateral motions are given it to keep the curve even. After the glass has thus been roughed out to approximate curve, a convex tool of the same diameter as the mirror, and faced with

squares of metal or glass, is used in grinding for several hours with each of a series of finer and finer abrasive grains, ending with powders of flourlike grain size. This leaves the glass uniformly curved from centre to edge and in fine-textured, smoothly frosted condition.

The full-sized tool is next covered with a quarter-inch layer of pitch, an elastic substance that will flow under pressure and thus continually conform to all changes made in the mirror surface. Against this pitch lap the mirror is polished for hours with wet optician's rouge (ferric-oxide) powder, or other polishing powders of microscopic grain size, until all scratches and tiny pits left by the grinding have been polished away and the surface is perfectly smooth to the eye and magnifier.

The next and most difficult but most interesting process is the figuring, in which the precision optician deals often with single millionths of an inch. With modifications of the means already used in polishing—that is, with pitch laps of varying sizes and shapes—the mirror is first brought precisely to a spherical curvature, one into which a huge sphere of which it is a segment would accurately fit. By further polishing in precalculated zones this sphere is then altered slightly to the paraboloid, which will bring the light rays to a single focus. This process, though the volume of glass removed is relatively infinitesimal, often consumes as much time as all the previous work or even more, especially since the behaviour is not entirely predictable and in removing one imperfection, such as a raised or depressed zone on the glass, others may be introduced. Figuring may be done with the machine described above, with frequent skillful readjustment of stroke, or by hand with small laps of pitch. At mid-20th century no machine had yet been devised to go through this figuring process automatically and to produce a perfect mirror without frequent human intervention guided by judgment based on test.

Prior to 1859 mirror makers enjoyed no satisfactory way of testing the figure of a mirror as it evolved, for the measurements involved are too small to be made by mechanical means. In that year the physicist Jean Bernard Léon Foucault (*q.v.*) invented a delicate test, even more delicate than needed, that reveals, locates and measures, within $\frac{1}{1,000,000}$ in., local surface irregularities, employing nothing more complex than a lamp shining through a tiny pinhole in an opaque screen and the edge of a common knife. To make Foucault's test an illuminated pinhole (artificial star) is placed at the centre of curvature of a spherical mirror. The rays go out from it to all parts of the sphere and are reflected back to a focus at the pinhole, the polished glass reflecting sufficient light for this test. To permit the rays instead to enter the eye the pinhole is displaced slightly to one side of the mirror's axis so that the rays will return slightly to the other side where the eye can be placed, a little back of focus, to receive them. The mirror is then seen to be bright all over. If now the knife edge is moved in from the side to cut the rays, the mirror, if everywhere precisely spherical, will darken uniformly all over; if it is not spherical, no point can be found at which it can be made to do this. Zones of longer or shorter radius of curvature than the rest of the mirror will be revealed by apparent shadows on its face, because the rays reflected from these zones encounter the side of the knife and do not reach the eye. The shadows exaggerate the relief of the surface about 100,000 times, and the mirror maker learns to interpret the code of these shaded areas in quantitative terms of mirror figure. Following these examinations he treats the faulty areas by brief, cautious local polishing and tests again; and thus proceeds until the desired paraboloid, free everywhere from irregularities of surface, is attained. By using an accessory plane mirror of high precision and making Foucault tests at the focus of the concave mirror instead of at its centre of curvature as just described, still greater delicacy may be attained.

Before use, astronomical mirrors must be coated with a metallic reflecting surface. Beginning early in the 1930s, silver deposited chemically on glass gave way to aluminum deposited physically by practical processes developed by John Strong, or chromium followed by aluminum developed by Robley C. Williams. Scraps of the metal are attached to tungsten wires a few inches or feet from the mirror, and the whole is enclosed in a chamber from which the air is pumped out to an almost perfect vacuum. An electrical circuit is closed, the tungsten wires become highly heated and the bits of metal, less refractory than the tungsten, are quickly vaporized. Unobstructed by air molecules, the atoms of vaporized metal fly across to the glass and condense in a highly reflective coating about $\frac{1}{250,000}$ in. thick.

These processes afford tougher, more resistant, longer-lasting coatings than does silver. They also reflect more of the actinic rays that affect the photographic plates used by the modern astronomer in place of visual observation. While the familiar aluminum surfaces are not mirrorlike, those formed by this method may easily be mistaken for a silvered mirror.

When aluminum is deposited on a glass surface which is not adequately cleaned, the adhesion will be inferior to that exhibited by a deposit on a properly cleaned surface. In most cases the mirror will appear to be good at first but will develop countless tiny blisters after standing for a day or so.

**Plane Mirrors.**—These mirrors, plane within $\frac{1}{400,000}$ in. or even $\frac{1}{800,000}$ in. and used as accessories with some astronomical instruments, are much more difficult to make than paraboloidal mirrors of equal diameter. A modification of Foucault's test or a test with Newton's fringes against a plane of known precision governs the figuring process, which consists of local polishing with small pitch laps. The finished plane is vacuum coated with reflecting metal. Since about 1913 glass or fused quartz planes called optical flats, made to the same precision by the same methods but not coated, have been in use throughout the mechanical industries for optically checking the accuracy of the precision gauges that make possible the manufacture of identical, interchangeable parts.

In the United States from time to time these flats, as they wear out of true, are checked at the national bureau of standards against a still more precise master flat, plane within $\frac{1}{4,000,000}$ in. (*See* also TELESCOPE.)

**Astronomical Mirror Making as a Hobby.**—Astronomical mirror making is a hobby for thousands of amateur astronomers who have made their own telescopes. In the 19th century amateurs discovered a scarcity of prepared instructions, partly because secrecy concerning the working methods had long been a tradition among professional makers, even though many of these had themselves begun as amateurs. This hindrance to the hobbyist was removed largely by the writings of W. F. A. Ellison, Russell W. Porter, Albert G. Ingalls and Allyn J. Thompson, beginning about 1920. Within the next decades tens of thousands of astronomical telescopes, principally of the relatively inexpensive reflecting type, were made in home workshops by amateurs, mostly adult.

In the reflecting telescope the mirror is at once the most important, the most difficult and the most interesting part to make. Thus, mirror making is itself a hobby within a hobby. The amateurs' mirrors, usually from 6 to 12½ in. in diameter, are made by modifications of the methods already described and usually by hand. The amateur's mirror disk, instead of being placed face up on a slowly rotating turntable and ground with a metal tool of lesser diameter, is placed face down on another glass disk of equal diameter, attached to the top of a barrel, and stroked with the hands back and forth across the lower disk with coarse, wet abrasive grains placed between the two. (The lower disk, called the tool, is later discarded.) The worker simulates the motions of the professional mirror maker's machine by keeping the mirror in gradual rotation with his fingers between the strokes, at the same time slowly walking sidewise around and around the barrel. The three combined motions keep the near-spherical curve from becoming lopsided.

The longer the grinding is continued the more concave the upper or mirror disk is ground out, the tool becoming convex to match its curvature. The concaving and corresponding convexing occur, instead of a uniform wearing down of the two flat faces, because the pressures automatically increase toward the ends of the strokes when the central areas of the upper disk press on the outer areas of the lower disk.

After a few hours of this preliminary roughing out, the mirror

concavity approaches the desired depth ($\frac{1}{20}$ in. for a typical amateur's mirror 6 in. in diameter). Series of finer and finer grains are then substituted for the coarse abrasive to produce as smooth a ground glass surface as can be had by grinding glass against glass. The tool is then covered with pitch and the mirror is polished five to ten hours against this medium with rouge; the process is essentially as described above for large mirrors made professionally, but the stroking is done by hand. The final figuring, or precise shaping within millionths of an inch, of the geometrically ideal paraboloid by eliminating local irregularities of surface such as zones that are high or low, is done by stroking the mirror in special patterns of motion against the same pitch lap on which it was polished. Foucault's all-revealing test is made every few minutes throughout the figuring, so that the worker may watch closely the new changes in curvature that spontaneously arise locally on the surface and decide on the next stratagem to steer the curve in the desired direction.

Because no two mirrors exhibit the same combinations of these deviations, the treatment cannot be standardized beyond a few general rules, which do not always apply. Within the limits of these general instructions the worker contributes from his own resourcefulness and imagination by devising methods, many of which prove fruitless or worse, forcing him to hours of effort to recover lost ground before he hits on a successful one.

Because the coating of the completed mirror with reflecting aluminum (superior to the more easily applied silver coating) requires too large an investment in high-vacuum apparatus, the amateur sends it to a laboratory to be coated, a brief procedure. He then plans and builds a telescope tube and a mechanical mounting with axes, so that his telescope may be easily pointed at different celestial objects.

**MIRROR WRITING:** *see* HANDWRITING.

**MIRZAPUR,** a city (including Vindhyachal since 1867) and district located in the Varanasi division of Uttar Pradesh, India. The city, headquarters of the district, lies on the right bank of the Ganges (Ganga), 55 mi. E. of Allahabad and 46 mi. W. of Varanasi city, close to the Vindhyan scarp and on a branch of the old Deccan road. Pop. (1961) 100,097. The town has stone ghats on the river, Hindu temples and mosques; there are two small parks, a town hall and a college affiliated to Agra university.

Mirzapur was founded probably in the reign of Shah Jahan (fl. 1627–58), about 7 mi. E. of the ancient Hindu town of Vindhyachal (Bindhachal), notable for the Vindhyeshwari temple, and became a river port. From 1800 to 1850 Mirzapur was the most important trading centre of upper India.

It attracted the cotton trade from the south and was a transit centre for river trade between central India and Bengal. With the advent of the railway to Allahabad in 1864, Mirzapur began to decline, though some local traffic continued. From 1921 its importance as a local trade centre increased, mainly because of its central situation, the introduction of road services and the growth of industries.

Nearly one-third of the population is engaged in trade and transport and about the same in production other than cultivation. Mirzapur is well known for its carpets, brass and metal wares, quarrying and dressing of sandstone. It is the only centre of lac industry in Uttar Pradesh.

MIRZAPUR DISTRICT (area 4,369 sq.mi.; 1961 pop. 1,249,653) extends southward across the Son valley, and is crossed east to west by the Kaimur hills. It falls into two regions, the narrow strip of the fertile Ganges plain and the southern upland which, especially south of the Son river, is a forest-clad, gneissic-metamorphic terrain with potential mineral sources. More than 65% of the land is irrigated by canals, the main crops being rice, wheat and barley. There is a cement factory at Churk and an aluminum factory at Pipri. The Chunar-Churk railway, the Son bridge at Chopan and the development of the Rihand project (started in 1956–57) have improved access to the district. A bus service links the plateau with Mirzapur city. (R. L. Sl.)

**MISAMIS OCCIDENTAL,** a coastal province on the northeastern part of the Zamboanga peninsula, Mindanao, Republic of the Philippines. Pop. (1960) 245,371.

Only 802 sq.mi., it is a small province facing Iligan bay. A narrow coastal plain gives way to rolling hills which partially encircle a mountainous mass centring on Mt. Malindang (7,954 ft.). A provincial highway follows the roughly semicircular shoreline. There are no roads into the rugged interior area. Coconuts and corn are the principal crops. The principal towns are Oroquieta, the capital, and Ozamiz, a chartered city and the principal port. (AS. C.)

**MISAMIS ORIENTAL,** a coastal province on northern Mindanao and including nearby Camiguin Island, Republic of the Philippines. Area 1,512 sq.mi. Pop. (1960) 388,615.

The area includes a narrow coastal plain and rolling to rough hill lands (dissected plateau). Some of the river valleys contain deep deposits of coarse alluvium. The principal products are coconuts, corn, rice and lumber. There is a large modern pineapple cannery at Bugo, but the fruit is grown in Bukidnon province, to the south. Cagayan, the capital and only city (pop. [1960] 68,274), is a secondary port and the principal air centre of Mindanao.

Hibok-Hibok, a volcanic peak on Camiguin Island, was active in 1948 and again intermittently from Sept. 1950 until 1952. (AS. C.)

**MISCARRIAGE,** a folk term for spontaneous abortion, the death and expulsion of a human fetus during the first 24 weeks of life. Expulsion of a dead fetus later in pregnancy is termed stillbirth. *See* ABORTION; STILLBIRTH.

**MISDEMEANOUR,** the term applied in Anglo-American law to an offense not otherwise classified as a felony or treason. In the early English law convictions for misdemeanours, unlike those for felony or treason, did not ordinarily result in forfeiture (*q.v.*) of the offender's goods or lands. Moreover, misdemeanours were not punished by death. In the modern law of England, misdemeanours include certain indictable offenses as well as petty offenses which may be tried summarily before a magistrate sitting without a jury. With the abolition of forfeiture in criminal cases in 1870 and the elimination of the death penalty in most cases of felony, the old distinctions between felony and misdemeanour no longer serve. In general, the law of England punishes misdemeanours less severely than felonies, although this is not true in every instance.

In most U.S. jurisdictions crimes are classified either as felonies or misdemeanours. The federal law provides for a subclassification of misdemeanours, known as petty offenses, to which the constitutional requirement of trial by jury does not apply. In U.S. law the classification of a crime as felony or misdemeanour is ordinarily determined by the penalties attached to the offense. A typical provision defines as misdemeanours those offenses punishable by fine or imprisonment in the county jail. Felonies are those punishable by imprisonment in the state penitentiary. Various consequences follow from these classifications. Thus, deadly force may be used to prevent the escape of one fleeing from a valid arrest for a felony, but such force may not be employed in misdemeanour arrests. On the other hand, the law may require that greater procedural safeguards be afforded one tried for felony than for misdemeanour. Offenses which were misdemeanours by common law or statute in England have sometimes been made felonies in the United States. These include conspiracy, attempt to commit certain crimes such as murder or burglary, perjury and obtaining property by false pretenses. *See also* CRIMINAL LAW; FELONY. (F. A. A.)

**MISE,** an Anglo-French term denoting any outlay of money and in particular the payment of taxation. The mise rolls (*rotuli misae*) of John's reign (1199–1216), which record payments made

from the exchequer to various departments of the royal household, illustrate the first meaning of the word. It was used to denote taxation in the document known as the *Confirmatio cartarum* granted by Edward I in 1297, when the king promised not to treat as customary certain "aids mises and prises" recently levied.

The word was also used to indicate the settlement of a dispute by arbitration. Louis IX's judgment (Jan. 1264) on the quarrel between Henry III and the rebel English barons was called the mise of Amiens, and after Henry's defeat at Lewes in May 1264 an agreement known as the mise of Lewes, of which the text is lost, was made between victors and vanquished.

**MISHAWAKA,** a city of St. Joseph county in northern Indiana, U.S., on the St. Joseph river 90 mi. E. of Chicago and adjacent on the west to South Bend (*q.v.*). Major industries produce rubber footwear, cushions, mattresses, automobile mats, raincoats, foundry supplies, packing products, electric power, sheet metal products and missiles. Bog iron discoveries in 1833 brought industry to the site, building blast furnaces and housing for workers; in 1839 the settlement was incorporated as Mishawaka, named for an Indian princess who lived in the area. In 1899 it was chartered as a city. It has a large Belgian population.

For comparative population figures *see* table in INDIANA: *Population.* (J. J. D.)

**MISHMI,** a hill tribe in the North East Frontier agency of India, inhabiting the valleys of the Dibang (where they are known as Midu) and the Lohit rivers. Those of the Lohit valley (numbering about 15,000 in the 1960s) are divided into two groups, the Miju on the upper Lohit and the Digaru on the lower reaches. The language is Tibeto-Burman, including different dialects. Both groups consist of exogamous patrilineal clans, the same named clans occurring among Miju and Digaru. Settlements are small and frequently shifted, low spurs being favoured sites for villages. There are no chiefs and each virtually autonomous family group, the true social unit, inhabits a long house built on piles. Agriculture is extremely primitive; maize (corn) and buckwheat are the staple crops; barley and wheat grow at higher altitudes, rice in the foothills. Cattle are kept for slaughter and are used as currency. Other occupations include hunting and fishing. Having access to Tibet and Assam, the Mishmi engage in substantial barter exchanging musk, medicinal herbs, paper bark and aconite poison for clothing, salt, copperware and swords. Tribal gods are worshiped with animal sacrifices and offerings, and there is evidence of Tibetan ritual influence. Slavery and head-hunting are no longer practised.

*See* J. P. Mills, "The Mishmis of the Lohit Valley, Assam," *Journal of the Royal Anthropological Institute*, vol. 82 (1952). (C. v. F.-H.)

**MISHNAH** (MISHNE), a collection of Jewish traditional laws, completed early in the 3rd century A.D. and comprising one of the two main parts of the Talmud.

*See* TALMUD: *The Mishnah.*

**MISIC, ZIVOJIN** (1855–1921), commander in chief of the Serbian army in the last year of World War I, was born at Struganik, near Valjevo, on Jan. 19 (new style; Jan. 7, old style), 1855, of a prosperous peasant family. He attended the Belgrade artillery school and received a commission in 1876. In that year and in the next two years he fought against the Turks and also fought in the Serbo-Bulgarian War of 1885. After graduating from the staff college in 1900 and being promoted colonel in 1901, he was for a time professor of strategy at the military academy. He served as head of the operations division of the general staff from 1907, became a general in 1912 and was deputy commander in chief in the Balkan Wars (1912–13). In World War I, when the Austro-Hungarian forces were launched on their second offensive, he was appointed commander of the Serbian 1st army. Then the battle of the Kolubara (Nov.–Dec. 1914) enabled the supreme command to announce: "Save for prisoners, there is not a single enemy soldier left in Serbia." Promoted field marshal, he distinguished himself in the retreat across Albania (Nov.–Dec. 1915). After sick leave (1916–17) he resumed his command at Salonika in 1917 and became commander in chief in 1918, to lead the army to victory. He died in Belgrade on Jan. 7 (N.S.), 1921.

(K. St. P.)

**MISIONES,** the extreme northeastern province of Argentina, bounded by Paraguay, Brazil and the Argentine province of Corrientes. Area, 11,506 sq.mi. Pop. (1960) 391,094. The province is characterized by abundant rainfall (70 in. per year) and a hot climate (mean annual temperature 22.78° C. [73° F.]). The rough terrain is accented by canyons, rivers and low ranges of the Sierra Victoria, Sierra Imán and Sierra Grande, largely covered with pine and broadleaf trees. The area was part of the region occupied by the famous Jesuit Guaraní missions in the 17th and 18th centuries (*see* GUARANI and PARAGUAY: *History*). It became an Argentine territory after several decades of dispute with Paraguay and Brazil and the bloody Paraguayan war of the 1860s.

The principal product is maté (Paraguay tea), followed by lumber and forest products, cotton, corn and tobacco.

The capital, Posadas, pop. (1956 est.) 52,200, established in 1865, is located on the upper Paraná river in the western corner of the province. River steamboats and a railroad from Asunción, Parag., to Buenos Aires link the city with the coast. The spectacular Iguaçu falls on the Brazilian border at the northern tip of the province is perhaps the best-known landmark. (Js. R. S.)

**MISIONES,** a department of southern Paraguay, lies between the Tebicuary and Paraná rivers. Area 3,025 sq.mi. Pop. (1962) 59,454. It was settled, as its name implies, by the Jesuit missionaries of the 17th and 18th centuries. Consisting almost entirely of a great lowland, much of it marshy, its chief economic importance is for cattle raising, although crops of rice, maize and sugar are also significant, and some maté is gathered.

San Juan Bautista (pop. [1960 est.] 6,488) is the capital, and San Ignacio, founded in 1609, an important centre for processing agricultural produce.

Both are on a major highway between Asunción and Encarnación, which bisected Misiones department and increased its importance and settlement. (G. J. B.)

**MISIONES, SIERRA DE,** an undissected piece of the Paraná plateau which forms the divide between the Paraná and Uruguay rivers (*qq.v.*) in the Argentine province of Misiones. It is incorrectly translated as "mountain" since actually it is only the height of land between two valleys, an interfluve. The top of the plateau in this area is about 1,500 ft. above sea level.

(P. E. J.)

**MISKITO COAST:** *see* MOSQUITO COAST.

**MISKOLC,** chief town of Borsod-Abaúj-Zemplén *megye* (county), northeast Hungary, 113 mi. N.E. of Budapest, lies in the valley of the Szinva, a tributary of the Sajó, on the eastern edge of the Avas hills which form part of the Bükk limestone plateau. Pop. (1960) 143,364 (mun.). The town lies partly in the steeper valley of the Bükk plateau and partly on the open plain. It has always been linked historically and commercially with Diósgyör farther up the Szinva valley where there are impressive remains of a 14th-century castle built by Louis the Great, and a small iron field which has supported some heavy industry in Miskolc. The heath country to the south, marked by the villages of Ónod and Muhó, was the site of the great struggle between Mongols and Magyars in 1241 when 80,000–90,000 Magyars were slaughtered as the Mongol horde swept through central Europe.

The established wealth and importance of Miskolc are apparent in some fine old buildings, including St. Stephen's, a 13th-century Gothic church. Miskolc is now the second industrial town of Hungary. It has long been an important market and a production centre for iron and steel, using local ore and lignite, and a variety of manufactures including flour mills, leather goods and wine. The limestone caves are used as cellars by the wine producers. The town has rail and road connections with Budapest and with eastern Hungary, Rumania and Czechoslovakia. (H. G. S.)

**MISPICKEL** or ARSENOPYRITE: *see* ARSENOPYRITE.

**MISPRISION,** a term in Anglo-American law, now almost obsolete, originally signifying a wrongful act or omission. In its surviving meaning the term means especially complicity in a crime, implying a degree of guilt less than that of the principal offender. One guilty of misprision is in effect an accessory. The term appears twice in the United States Criminal code. One owing

allegiance to the United States is guilty of misprision of treason if, having knowledge of an act of treason, he conceals the fact and does not disclose it to the proper authorities. Misprision of felony is the similar concealment of, and failure to disclose, knowledge of any felony cognizable by a court of the United States. Both are felonies, and the punishment for misprision of felony may be more severe than that for the principal offense itself. (B. Ce.)

**MISRULE, LORD OF,** the name applied in England in the late medieval and Tudor period to the master of the Christmas festivities held at court, in the houses of great noblemen, at the Inns of Court and in Oxford and Cambridge colleges. His reign (either from Oct. 31 to Feb. 3 or for the traditional 12 days of Christmas) was a period of wild festivity and buffoonery. The practice probably originated with the licence allowed to slaves at the Roman Saturnalia (*see* SATURN); it is traceable through the earlier medieval feast of fools, whose ruler was sometimes called king of the bean (*see* FOOLS, FEAST OF). Both these figures were in effect the old "winter king" of ancient rite.

The lord of misrule, in Scotland called the abbot of unreason, should not be confused with the Tudor court official called the master of the revels who was responsible for entertainments throughout the year. After the death of Edward VI (1553) there is no record of the election of a lord of misrule, and the Scots suppressed the abbot of unreason in 1555. *See* also BOY BISHOP.

*See* Sir J. G. Frazer, *The Golden Bough*, 3rd ed., vol. vi (1907–15).

**MISSAL,** the book containing the prayers, important chants and necessary instructions for the celebration of the Mass (Latin *missa*, hence also *missal*) in the Latin rite of the Roman Catholic Church. The structure and mode of expression of the Mass is strongly influenced by the Jewish religious world out of which Christianity emerged. This influence is evident particularly in the Foremass, or earlier section of the Mass, and in the preface. Literary evidences of early Christian practice from which a history of the books that lead up to the modern missal may be constructed may be said to begin with the *Didache* (*see* APOSTOLIC FATHERS), a little manual containing, among other things, prayers for the Christian assemblies and dating from around the year 100. A description of the mass as celebrated in Rome around the year 150 is given by Justin Martyr in his *First Apology*. Justin gives no quotations of liturgical texts, perhaps because wide latitude for improvisation was the rule at that time. The *Apostolic Tradition* of St. Hippolytus, a Roman priest of the early 3rd century, exerted considerable influence on the Eastern liturgies while receiving little attention at Rome itself.

The precise origins of the Roman rite are obscure, but its framework is considered to have been essentially fixed by the beginning of the 5th century. At that period, each actor in the sacred drama had his own book. The priest at the altar used the sacramentary, a book containing the orations and prefaces that vary from feast to feast. The fixed prayers which form the Ordinary of the Mass were at first either memorized or written on a separate tablet placed on the altar. Soon, however, they were included in the sacramentary. Among the important extant sacramentaries are the Leonine, traditionally attributed to Pope St. Leo the Great (440–461); the Gelasian, attributed to Pope St. Gelasius I (492–496); and the Gregorian, attributed to Pope St. Gregory the Great (590–604). All three are actually composite works and products of a considerable evolution.

For the scriptural readings used in the Mass, the custom was initially to use a copy of the Bible with the passage to be read marked. Such a copy of the Scriptures was called the Apostolus when used by the lector in chanting the Epistle and the Evangelium when used by the deacon in chanting the Gospel. In time, particularly after the year 1000, a special book, the lectionary (*q.v.*), was developed which contained only the Epistles and Gospels to be chanted on each feast. The soloist who led the congregation in the responsorial singing of the psalms used a book called the cantatorium. Distinguished from this latter was the antiphonary (*q.v.*) used by the *schola cantorum*. This group of singers some time after the 4th century took over the matter contained in the cantatorium, and their book was also called the gradual (*q.v.*) because it now contained the verses traditionally sung by the soloist from the step (*gradus*) below the place from which the Gospel was chanted. Finally, a separate book, the *ordo* (*see* ORDINES ROMANI), of which examples survive from the 7th century, gave the directions for the proper carrying out of the liturgical functions.

As the custom grew, however, from the 8th century onward, of less solemn celebration in which the priest said the whole service, the contents of these separate books came by degrees to be combined into a single volume, the *Missale plenum* ("full missal"), which by the 15th century had replaced the older books. All modern missals are of this type. The *Missale plenum* existed in various forms, the most popular being the missal of the Roman curia, which had developed, chiefly it would appear under Pope Innocent III (1198–1216), a simple, uncluttered Mass rite. This missal was adopted by the Franciscan friars and spread by them throughout Europe, becoming particularly widespread after the invention of printing and paving the way for the reform under Pope St. Pius V. Another form of special importance because of its influence on the composition of the Book of Common Prayer was the slight variant of the Roman curial missal employed in the so-called Sarum use, the rite of southern England in pre-Reformation days.

The multiplicity of liturgical forms led Pope St. Pius V, at the instance of the Council of Trent (1545–63), to promulgate in 1570 a new missal, enjoining its general adoption throughout the Latin rite. This missal subsequently underwent constant though not radical revision under Clement VIII (1604), Urban VIII (1634), Leo XIII (1884), Benedict XV (1920) and John XXIII (1961). The 20th century has witnessed a notable quickening of change under the impact of the liturgical movement (*see* LITURGICAL MOVEMENT, ROMAN CATHOLIC), leading to the revision of the liturgy of Holy Week under Pius XII in 1955 and culminating in the decree of the second Vatican council (1963) allowing the introduction of the vernacular in the variable parts of the mass and ordering a complete revision of the missal to be carried out by a postconciliar commission.

A similar process toward amalgamation of the books used by the celebrant in the liturgy of the Eastern churches has failed to win general acceptance, although the Anthologion, an Eastern semiparallel to the Western missal, enjoyed some popularity beginning in the 15th century, with an edition appearing in Athens as late as 1882. Small hand missals for the use of the faithful, however, are not uncommon in Eastern churches. *See* also MASS.

**MISSI DOMINICI** (Lat. envoys or commissaries of the sovereign), officials sent by some Frankish kings and emperors to supervise the provincial administration. Under Charlemagne at the beginning of the 9th century they were sometimes also called *missi imperatoris* (envoys of the emperor); in capitularies issued in 861, 862 and 864 by Charles II the Bald, the term *missi rei publicae* (envoys of the commonwealth) was used.

The Merovingians and the early Carolingians had occasionally sent special envoys on particular missions, but the use of *missi dominici* did not become a normal part of the administrative machinery till the time of Charlemagne. At least from 802 onward almost all the empire was periodically divided into *missatica* or inspection circuits, the frontiers of which seem sometimes to have been changed. In theory four months of every year were to be spent on the inspection of each area; but in practice the commissions were probably not sent out very regularly and their work was still occasionally supplemented by the use of special envoys. At least two *missi* were sent to each district, one a bishop or an abbot, the other a layman, probably a count (*q.v.*). During their tour of duty they were, by imperial command, lodged and fed at local expense.

The *missi* had full powers of investigation. No individual or group could evade their searching inquiries, designed to expose all scandals and intrigues. They were to rectify all error and injustice and thus they were the natural protectors of the weak. They could reserve difficult or doubtful cases to the imperial tribunal and could themselves consult the growing collection of capitularies (especially the *capitula missorum*; *see* CAPITULARY) in the palace archives or seek supplementary instructions from

the sovereign. It was their duty to administer the oath of allegiance normally exacted from all freemen on the accession of a new sovereign or a change of title. They informed the local communities of the content of imperial decrees, so that none could plead ignorance of the law. They also invited comment on the decrees. Thus on returning from their mission they could give an accurate account of existing conditions and needs, by reference to which legislation could be framed or modified. The *Admonitio generalis*, a series of instructions issued by Charlemagne in 789, probably followed an inspection of this sort; and the inquiry of 802 certainly led directly to the promulgation of a general capitulary for the guidance of the *missi*, with special instructions applicable in particular conditions.

The *missi* who wielded these powers were men of the great consequence, protected by the same wergild or fine payable for injury to life or limb as was granted to members of the sovereign's family. They were presumed to be men of unquestionable integrity; and, until the reign (814–840) of Louis I the Pious, they were always appointed to serve in districts where they were strangers. But the difficulties which sapped the life of the empire after about 830 paralyzed and finally destroyed this vital institution. After 870 the system showed signs of breakdown, and by the end of the 9th century it had almost completely disappeared.

**MISSILES:** *see* ROCKETS AND GUIDED MISSILES.

**MISSION, CONGREGATION OF THE** (VINCENTIANS or LAZARISTS; CONGREGATIO MISSIONIS; C.M.), a Roman Catholic society of missionary priests and brothers with private vows, founded at Paris in 1625 by St. Vincent (*q.v.*) de Paul for the purpose of preaching missions to the poor country people and training young men in seminaries for the priesthood. It was approved in 1632 by Pope Urban VIII. The Vincentians arrived in the United States in 1816 making their first foundation at St. Louis, Mo. They conduct three universities in the U.S.—DePaul (Chicago), Niagara and St. John's (New York)—and staff 20 seminaries. Among other works of the American provinces are missions in Panama and Formosa, preaching, chaplaincies and parishes. The congregation labours in more than 62 countries. *See* also ORDERS AND CONGREGATIONS, RELIGIOUS.
(J. G. Nu.)

**MISSIONARY RIDGE:** *see* CHATTANOOGA, BATTLE OF.

**MISSIONS** is the term used to denote organized efforts for the propagation of a religion. The agents of propagation have been known as missionaries. Though this article deals with the history of Christian missions, Buddhism and Islam are also missionary religions. Some schools of Hinduism have begun missionary activities in modern times. Zoroastrianism and to some extent Judaism were once missionary religions.

Christian missions in the modern period have been divided into "foreign" and "home" categories. Foreign missions indicate evangelistic efforts directed to regions and peoples beyond the boundaries of the nation in which the sending agency is located, but does not normally include pastoral ministry to emigrants from that country. Home, domestic or inner missions indicate church extension and ministry to special groups within the national boundaries.

Younger churches have arisen in almost all countries of Asia, Africa, Latin America and Oceania as a result of former missionary endeavours and they also are beginning to undertake evangelism abroad. Western churches have at the same time come to recognize that their own secularized countries are now properly mission fields.

Consequently the term foreign missions is becoming obsolete and is being replaced by world mission. Missions is increasingly being used to denote the agencies of propagation and the academic study of the subject, also known as missiology.

The traditional organization of the history of missions has undergone considerable change, largely as a result of the studies of Kenneth Scott Latourette. Edward Caldwell Moore demonstrated that expansion had not been continuous but rather characterized by periodicity. Eras of expansion were followed by periods of arrest. Latourette interpreted this periodicity as a pattern of advance and recession in an ascending spiral. Each major wave of expansion has been followed by one of recession. However, each new wave of advance has set a new high mark, has lasted longer and has ascended more rapidly, while each succeeding recession has been briefer in its duration and less severe in its losses. The seeds of each new advance have been planted in the preceding time of retreat. This pattern eventually works out in the future in an almost steadily ascending line of advance. The periods as defined by Latourette were: (1) the first great advance, to about A.D. 500; (2) the first great recession, from 500 to about 950; (3) the second advance, roughly from 950 to 1350; (4) the second major recession, from about 1350 to 1500; (5) the third advance, from 1500 to 1750; (6) the third recession, from about 1750 to 1815; and (7) the "Great Century" of expansion, from about 1815 to 1914. The contemporary period is too close at hand to estimate accurately, but the definite advent of a new period in missionary theory and practice after World War II would indicate that the intervening years are best treated with the preceding century. Even those who on historical or theological grounds cannot accept Latourette's theory about a definite pattern of expansion and his prophecy of the future nevertheless find his periods, or a modification of them, useful for the organization of the history of missions.

## EARLY HISTORY

**First Advance to A.D. 500.**—The Christian world mission arises out of the life and ministry of Jesus Christ, but it has antecedents in universalistic prophetic Judaism, which combined ethical monotheism with the vision of a world community of men, equal as individual creatures before their Creator and sovereign God. Ultimately the origin of the mission is found in the idea of God acting in history for the salvation of mankind. Prophetic universalism culminated in the conviction of the early church that God was in Christ reconciling the world unto Himself. The Gospel, being both the message of Jesus and the message of the early Christians about Jesus, was directed to all men and was free from any national and racial limitation. The heart of this Gospel is the affirmation that Jesus Christ is Saviour and Lord. The church appropriated to itself the Hebrew prophets' concept of the true Israel as a faithful remnant saved to save the world. An evangelistic obligation was recognized as being inherent in discipleship.

From the beginning until modern times, although there have been many subordinate motives from time to time, the chief motivation of the mission has been the church's obedience to the Great Commission given by the risen Lord: "Go therefore and make disciples of all nations, baptizing them in the name of the Father and of the Son and of the Holy Spirit, teaching them to observe all that I have commanded you; and lo, I am with you always, to the close of the age." This obedient witnessing by the church then becomes the agency through which the Holy Spirit convinces men that Jesus Christ is Lord and Saviour.

The Christian faith first expanded through the communities of the Jewish dispersion. After a brief struggle with a Judaizing element within the church, the universal character of the Christian faith and practice was acknowledged and freed from the requirements of Hebrew law and ceremonial. The church spontaneously embarked on its task of winning the nations, a total commitment reflected in the tradition that the 12 apostles each took responsibility for a definite geographic area. There was an officially commissioned roving missionary ministry, of which Paul and Barnabas are examples. However, extensive evangelism was done by ordinary laymen in day-to-day contacts and especially as they traveled. Paul, the greatest and the prototype of all missionaries, evangelized much of Asia Minor and the chief Greek cities and was active in Rome, despite his status as a prisoner. The new religion spread rapidly along the trade routes into all the great centres of population. By the 2nd century the roving missionaries appear to have ceased to exist, and evangelistic responsibility came to rest upon the bishops.

Christianity had spread to all parts of the Roman empire by the

time of Constantine, aided by the prevailing peace, easy communication, the use of Greek as a universal medium of communication, a growing identification of the faith with Hellenism, and the widespread spiritual hunger of the time. Estimates of its numerical strength vary from one-twentieth to one-half of the population. It was strongest in Asia Minor and weakest in the northern and eastern European provinces, Palestine, Phoenicia and Arabia. Persecution by the state aided Christianity's expansion, because "the blood of the martyrs became the seed of the Church." The first totally Christian states arose east of the Roman empire. The city-state of Edessa was first, and became the base for further eastward and northern expansion. Armenia at the end of the 3rd century became the first large country to undergo mass conversion at the command of its king. Gregory the Illuminator was the apostle to this nation. East of the Roman empire, however, the growing alliance of Christianity with Rome and with Hellenistic culture hindered the spread of the faith just as much as it favoured it within the empire.

Mass movements within the Roman empire became increasingly prevalent after Constantine granted toleration and his successors gradually adopted Christianity as the state religion, suppressed paganism with increasing severity and sought religious uniformity. Although paganism lingered long, by A.D. 500 the population of the Roman empire was almost solidly Christian. During this period the real missionary endeavour had moved to the borders of the empire and beyond them. The Germanic tribes were mostly converted before they invaded the empire, and this lessened the destruction and brutality which accompanied the invasions. The outstanding missionaries of the period were: Ulfilas, who evangelized the Goths; Martin of Tours, the great missionary of central Gaul; and Patrick, the apostle to Ireland. Outside the empire permanent Christian communities were established in Ethiopia by Frumentius of Tyre and in India, where the Syrian Malabar Christians still claim the Apostle Thomas as their founder and where the church had certainly been established by the 3rd century. Nestorian episcopal sees were established as far into central Asia as Merv and Herat in the 5th century.

**Losses and Gains to A.D. 950.**—*Losses.*—The church had won the Roman empire, but the disintegration of that empire with which it had become identified threatened the existence of Christianity. Such losses as resulted from the invasions of the Germanic peoples and others out of eastern Europe and central Asia were only temporary, but the Arab invasion of the 7th and 8th centuries established Islam as the dominant religion in about half the area where Christianity had previously claimed all or a majority of the population. The older faith was completely eliminated in north Africa and Arabia and in the territories from Egypt eastward it was slowly strangled. There the churches remained as minority enclaves usually associated with a particular nationality, always under pressure and slowly dwindling.

*Celtic Missionaries.*—Many of the Germanic tribes which invaded western and central Europe held to the Arian form of Christianity, and Catholic Christianity was faced with the twofold task of healing the breach of heretical schism and of converting the pagans. The conversion of the pagan Franks to Catholic Christianity, symbolized by the baptism of their king Clovis (496 or 506?), marks the turning point toward success in both efforts. While losses were occurring in the Mediterranean area, there was steady advance into northern and central Europe. The missionaries in the initial advance, however, did not come from the older centres of the faith, but from its remote northern outpost. They were the Celts, first from Ireland and then from Scotland. These Celts were monks, as all the chief agents of missionary expansion were now to be until the rise of Protestant missions. Their motive seems to have been as much ascetic discipline and renunciation as evangelism, for the self-imposed exile from the beloved homeland plays a part in their actions. A leader who had taken such a vow would frequently associate with him a band of 12 companions in imitation of Christ and the Twelve. Columba (b. 521) established Iona as a centre for the conversion of Scotland, and then brother Celts of that land were recruited for the mission. They went from Ireland and Scotland into England, the Orkneys and Faeroes, the Frankish kingdoms, the Low Countries, the Alpine region, the Danubian lands, and even into Italy. The greatest names after Columba are Columban (b. 543), who after heroic labours in the Vosges and the Burgundian kingdom established the monastery of Bobbio in northern Italy and died there in 615; his companion, Gall or Callech; Aidan, the first bishop of Lindisfarne; and Cuthbert, who evangelized Northumbria from Lindisfarne.

The southward penetration made by the Celtic missionaries brought them into conflict with the growing hegemony of Rome over the western church, because they did not acknowledge Roman claims to special authority, their spontaneity and individualism clashed with the Roman sense of order, they followed a different calendar from that of Rome, and their rite was also considerably different. Just as Celtic leadership in the mission came to an end, it was taken up by the Englishmen whom they had brought to Christianity.

*English Missionaries.*—It was in England that Celtic and Roman claims were resolved in favour of the latter and the two streams merged in a new missionary force. Pope Gregory I sent a mission under Augustine to England in 596, the first instance of such papal initiative. Canterbury, the capital of Kent, was the base of the mission. Theodore of Tarsus completed Augustine's work, and then largely through the efforts of Wilfrid royal support was won for Roman control and customs. The English missionaries to Europe, therefore, extended Roman hegemony in the areas where they laboured. Wilfrid, Willibrord, and the great apostle to the Germans, Wynfrith, renamed Boniface, firmly planted the faith in the Low Countries, East Frisia, Saxony and Bavaria.

Boniface, who began his missionary career in 716, received a papal commission to the Germans east of the Rhine in 719. He converted the pagans, established ecclesiastical order, fostered civilization and established Benedictine monasteries as bases for evangelism and Christian nurture. He was martyred by pagan Frisians in 754. The base of the English mission was sadly weakened by Viking raids and invasions, but Frankish missionaries joined in the work of their teachers. Ansgar (Anskar or Anschar) (801–865) is an example. Visions had called him to a missionary apostolate from the time of his youth. Established as bishop of Hamburg, he initiated a mission to all the Scandinavian peoples.

After the death of Boniface a reaction in Sweden and Denmark wiped out most of the gains. Under Charlemagne the coercive power of the state had been used to complete the conversion of the Saxons.

*Byzantine and Nestorian Missionaries.*—Agents of the Greek church in Constantinople pressed northward into the Balkans. The Bulgars were won by the 9th century. The brothers Cyril and Methodius were sent to Moravia by the patriarch at the request of the ruler, Rastislav, about 863. Their methods and their translation of the Bible and the liturgy into Slavonic were not only successful in Moravia but assisted in the conversion of other eastern Slavs. The western Slavs were simultaneously being evangelized by Roman Catholic agents, and Saxon military pressure favoured their work among the Czechs. Methodius allied with the Latin church. A mission to the Russians was begun about the 9th century. Farther east the Jacobites and especially the Nestorians were active. The Islamic conquest of Persia inflicted a setback of great severity, but the Nestorian penetration of central Asia continued. The Turks were given a patriarch in the latter part of the 8th century, and churches were established in Sinkiang. Alopen introduced the faith in the capital of China, Ch'ang-an, in 635. The mission flourished under imperial favour, and a patriarchate for China was established early in the 8th century. However, the church was crippled by persecution under the emperor Wu Tsung in 845 and thereafter speedily disappeared, although Christianity lingered on west of the frontiers of China.

**Later Middle Ages.**—*Advance in Europe and Asia.*—The flowering of medieval European culture was accompanied by four centuries of missionary expansion, and during this period the conversion of Europe was completed, the Russians were won, missions to Islamic areas were begun, and the faith was taken once

more to China. The most spectacular advance of Christendom against Islam was in the reconquest of the Iberian peninsula and Mediterranean islands and in the crusades. These military ventures were not the result of missionary motivation, however, and they erected a permanent barrier of bitterness between Islam and Christendom.

Contrasted with the militant crusades are the methods of loving persuasion attempted by Francis of Assisi and Ramon Llull (martyred in 1315 or 1316). Both the Franciscan and Dominican orders created special missionary organs and sent their friars throughout the Islamic world. They endeavoured to win the ancient churches of the orient to obedience to Rome in the hope of making them potent missionary agencies to the Muslims.

The conversion of the Scandinavian peoples begun by Ansgar went forward under the active direction of the Viking kings. Canute left Denmark thoroughly Christianized when he died in 1035. Haakon, Olaf I Trygvesson and Olaf II Haraldsson during the second half of the 11th and first half of the 12th centuries completed the Christian conquest of Norway, the islands to the north and Iceland, and under Olaf Trygvesson the faith reached Greenland. Olaf Skotkonung and his sons at the same time used less force and were just as successful in Sweden. The conversion of the remaining peoples of eastern Europe took place during the 10th and 11th centuries. The Magyars were converted fully by the end of Stephen I's reign in 1038, and the Poles had been won at the same time. Unhappily, much coercion by the state then appeared. The Saxons and Poles imposed Christianity on the Wends in the course of conquest, and the Knights of the Sword or *Fratres Militiae Christi* followed the same pattern in East Prussia and the Baltic states.

The Russian ruler Vladimir was converted to Orthodox Christianity *c.* 987, and the progress of national conversion went steadily forward, the church contributing powerfully to the formation of Russian culture. The Mongol invasion of the 13th century temporarily weakened the church in some areas but speeded up its efforts to convert the northern regions of the country beyond Mongol control. Stephen of Perm (1330–90), an outstanding figure in this northward movement, was a missionary to the Finns.

The Mongol invasion devastated the Christian communities of central Asia, but once the Mongols settled down to rule their conquests the prevailing peace favoured missionary endeavour. Nestorian, Franciscan and Dominican missionaries penetrated the Mongol territories, and the first two reached China. The court favoured both the numerous Nestorian agents and the Franciscan mission under Giovanni di Monte Corvino, who arrived in the capital in 1294. However, both forms of Christianity were too closely identified in the popular view with the Mongol rule and were swept away in the Ming restoration. The rise of the Seljuk Turks, newly converted to Islam, and the disintegration of the Mongol power turned the tide against Christianity in central Asia.

*Losses From 1350 to 1500.*—The setback in China and central Asia was the beginning of a serious recession. The Ottoman Turks came to the fore as the dynamic force in Islam, replaced the Arab state with a new empire, destroyed the Byzantine empire, captured Constantinople in 1453, conquered the Balkans, and were turned back only at the gates of Vienna.

Although the Christian churches in the Balkans were not destroyed, Islam became the state religion there and large Islamic elements were introduced into the population. Elsewhere under Turkish rule the old Eastern churches declined still further. The Black Death carried off hundreds of missionaries who were not replaced. There was little concern about evangelism for more than a hundred years.

**Roman Catholic Advance, 1500–1750.**—In this period Christianity first became a world religion. The voyages of discovery resulted in a new world view and expanded the horizons of Europeans. Three new Roman Catholic empires arose and their courts were burdened with a sense of obligation for the evangelism of their subjects—Spain, Portugal and France. The pope divided the dominion of the newly discovered territories between the monarchs of Spain and Portugal and imposed upon them responsibility for sending and maintaining missionaries and for building churches and protecting Christians.

Unfortunately the agreement included awarding ecclesiastical patronage in both areas to the crown, and this was to become a stumbling block to adequate deployment of the missionary force. However, it was not so much the colonial policy of the states as a new spiritual vigour within the Latin church which reformed it internally following the Protestant revolt and recalled it to its missionary obedience. The Franciscans, Dominicans, Augustinians and other older orders took up the mission work again with increased zeal, and a new order, the Society of Jesus, became a major factor in the advance.

The foundation in 1663 of La Société des Missions Étrangères de Paris (the Foreign Missionary Society of Paris) demonstrates that in some parts of the church zeal was not confined to the monastic orders. The object of this organization was—through the work of secular priests, not monks—to raise up quickly a secular indigenous clergy in mission lands. Central direction to the whole vast enterprise was provided by the establishment at Rome in 1622 of the Sacred Congregation for the Propagation of the Faith (*Sacra Congregatio de propaganda fide*), by which papal responsibility for the mission was acknowledged and papal control effected. It was concerned with the assignment of territory, ecclesiastical relationships and the support, training and direction of missionaries. Its value was soon demonstrated not only in the expansion of the mission but also in protecting the local missions from domination by colonial officers.

Evangelization went hand-in-hand with the military conquest of Central and South America, the islands of the Caribbean, and the Philippines, where neither primitive society nor religion could withstand the invaders. The missionaries and their supporters among the Spanish colonists strove valiantly to mitigate the horrors of conquest and to protect the natives against exploitation. Bartolomé de las Casas, appointed protector general of the West Indies, is the best-known missionary. Conversion was superficial but at least nominally complete before the end of the period. French colonial policy in North America, unlike that of the Spanish, sought to interfere with Indian life as little as possible. Evangelization, therefore, was not coercive. Missionary work was perhaps in consequence even more heroic than in Spanish territories, but missionary martyrs were more the victims of involvement in intertribal hostilities than of religious persecution or antagonism.

Portuguese colonial expansion was directed to India and the far east, with the major exception of Brazil. Africa was chiefly regarded as an obstacle to be circumnavigated, although there were some minor colonial and missionary ventures there. A Christian kingdom of the Congo existed in the first half of the 16th century. Although numerous orders served in the east, it was the Jesuits pre-eminently who were associated with major developments. Francis Xavier (1506–52) was the great apostle to these peoples. Commissioned as papal nuncio to India and the east, he arrived in Goa in 1542. He laboured among the Parava pearl fishermen near Cape Cormorin, in Travancore, Ceylon and Malacca, and established at Goa a training college for youths from many lands who would return as missionaries. Then he founded a mission in Japan, and seeking to enter China died on an island near Macao. The mission in Japan flourished, and in 1603 there were about 300,000 Christians. However, a series of persecutions of extreme severity began in 1587 and lasted for a half a century. Christianity was proscribed, thousands were martyred and Japan isolated itself from the western world. Great success attended the mission in China under the able leadership of the great Jesuit Matteo Ricci and his successors. The court favoured the mission, and an edict of toleration was proclaimed in 1692. Interorder quarrels, climaxing in the rites controversy, however, incurred the anger of the emperor and brought disfavour and repression on the Christians. Despite the exclusion of missionaries, persecution and isolation, a community of about 250,000 remained at the end of the 18th century. The Dutch drove the Portuguese from Indonesia and Ceylon and excluded Roman Catholic missionaries. Little was accomplished in Malaya, Burma and Thailand, except that the last of these became the base for a large-scale operation in Indo-

china. A large membership was raised in the states of Cambodia, Cochin, Laos and Annam. The Foreign Missionary Society of Paris was the chief agency there. Through intervention for the protection of the missionaries, French influence became predominant in the area. Throughout the whole of south and east Asia, Spanish and Portuguese claims to control ecclesiastical appointments interfered with effective missionary work. Partly to overcome this difficulty and partly to ensure direct oversight of the missions, the Propaganda created few new sees and appointed vicars apostolic instead of diocesan bishops with full episcopal powers. The vicar apostolic was consecrated as the titular bishop of some extinct see and was invested with the personal privileges and powers of a bishop and was assigned to a region where he exercised episcopal powers, not in his own right, but as the personal representative of the bishop of Rome.

**1750 to 1815.**—Latourette regards the period from 1750 to 1815 as a time of recession. Missionary interest declined, contact with China was cut off, some Indians in South America reverted to paganism; but there was no great loss of territory. This was a time of wars which disrupted the home base, and the disintegration of the Portuguese and Spanish empires adversely affected missions. Another cause of diminished activity was the dissolution of the Society of Jesus.

## PROTESTANT MISSIONS

The Protestant churches were slow to undertake missions. In the 16th, 17th and 18th centuries the expansion of Protestantism outside Europe was through emigration, especially to North America. Efforts were made to provide pastoral care for such emigrants and for soldiers, officials and merchants in colonial outposts. Two British foundations, the Society for Promoting Christian Knowledge (1698) and the Society for the Propagation of the Gospel in Foreign Parts (1701), were established for this purpose. Protestant monarchs and their governments in general were not as zealous as the Roman Catholic monarchs in evangelizing their new subjects. However, the Virginia and Massachusetts charters mentioned the propagation of religion, and the chaplains of the Dutch East India company were required to instruct and baptize natives. Contacts with subject peoples or aborigines in the colonies did inspire some missionary efforts. Thus John Eliot's mission to the Indians in Massachusetts drew support from persons in the colony and in the homeland and led to the creation of the Society for the Propagation of the Gospel in New England in 1649, the first genuine missionary society. The Mayhew family began, in 1641, 150 years of service to the Indians of Martha's Vineyard and Nantucket, and there were other ventures, such as the Stockbridge mission. Added to the influence of such examples as these, the voices of Adrianus Savaria, Justus van Heurn, Justinianus von Weltz and a few other prophets called the churches to their missionary obedience.

It was German Pietism which brought forth continuing missionary activity on a large scale. Philipp Jakob Spener, the father of Pietism, advocated missions, and his successor as leader of the movement, August Hermann Francke, made the University of Halle the centre of missionary zeal and training. The missionaries recruited and trained by Francke were sent to Tranquebar in India by King Frederick IV of Denmark beginning in 1705; this monarch having more zeal for missions than his fellow Protestant rulers. The first two missionaries were Bartholomäus Ziegenbalg and Heinrich Plütschau. A lively correspondence among Francke, the missionaries, persons in England associated with the S.P.C.K. and Cotton Mather and others in America diffused knowledge about the enterprise and stimulated interest. Out of the same Pietist circle came Count Nikolaus Ludwig von Zinzendorf. Under his leadership the Moravian refugees on his estate at Herrnhut recovered the apostolic vision and purpose, and the reborn Moravian Church made the mission the chief reason of its existence. The first missionaries went from Herrnhut to St. Thomas in the West Indies in 1731, and within a decade Moravian missionaries were to be found from Greenland to the Cape of Good Hope. The example and spirit of their work influenced John Wesley, William Carey and the founding fathers of the British missionary societies.

Seeing no hope of persuading the churches officially to accept responsibility, the advocates of missions moved to establish voluntary societies. The publication in 1792 of William Carey's *Enquiry into the Obligations of Christians to Use Means for the Conversion of the Heathens* crystallized sentiment and brought action. Carey and a dozen fellow ministers organized the Baptist Missionary society in Oct. 1792, and the following year Carey and John Thomas went to India as the first agents of the society. The London Missionary society was founded in 1795 by ministers and laymen of several denominations; and the Evangelicals in the Church of England organized the Church Missionary society in 1799. The Netherlands Missionary society began in 1797. Thus by the close of the 18th century continuing organs for missions had been established by Protestants.

### Protestant Missionary Advance, 19th and 20th Centuries

The upsurge of missionary interest so apparent among Protestants during the last decade of the 18th century continued steadily to gain momentum throughout the 19th century, which Latourette called the "Great Century" of Christian expansion. The colonial outreach of Protestant European powers broadened the horizons of their people just as the age of discovery had done for the Roman Catholic portions of Europe. The political and cultural prestige of Europe aided missionaries in penetrating all parts of the globe, as did also the development of communications and the relative prevalence of peace. The Industrial Revolution provided rank and file church members with the means of supporting missionaries in increasing numbers. The chief motive was once again obedience to the Great Commission. The aim was the proclamation of the Gospel, and the program was developed experimentally as need and opportunity demanded.

There was no generally accepted theoretical basis and little attempt to provide it until Gustav Warneck founded the study of *Missionswissenschaft* in Germany in the late decades of the 19th century. Looking at needy humanity through the eyes of Christ, the missionaries reached out hands of compassion and proclaimed the Gospel by deed as well as by word and life example. They gave the people the Bible in their own language, after first reducing many languages to writing; they instructed them in modern knowledge as well as in Christian life and doctrine; they taught them to read and write; and they healed their diseases. The vernacular Bible, the schoolbook, and the medicine bag soon became the constant companions of the missionary. The printing press, the school, and the hospital alongside the church became identifying marks of Protestant mission stations. Ignorance, illiteracy and physical suffering were regarded as belonging to the realm of Satan and to be vigorously assaulted. Converts were gathered into churches, but it remained a weakness of Protestant missions in general that until the fourth decade of the 20th century there was much more stress on winning individual allegiance to a "Christian movement" than on building the corporate community, the church. However, by the middle of the 19th century the aim of the missionary enterprise was, in the terms of Henry Venn in England and Rufus Anderson in the United States, the fostering of "self-governing, self-supporting, self-propagating churches."

Missionary agencies increased with each new decade. In Great Britain the Wesleyan Methodist Missionary society was founded in 1813; it embarked on genuine missionary work as well as pastoral service to colonists; and the Glasgow and Edinburgh societies were replaced by an official Committee on Foreign Missions of the Church of Scotland, an exception to the usual pattern of voluntary societies. The interdenominational Basel Mission society for Switzerland and Germany was established in 1815, and the Leipzig, Berlin, Rhenish and other societies followed.

The foreign missionary enterprise of U.S. churches is popularly held to begin with the foundation of a mission band at Williams college in 1806. When some of these men appealed to the Congregational churches of Massachusetts to be commissioned and supported in missionary service, the American Board of Commissioners for Foreign Missions was founded in 1810. It served several Presbyterian and Reformed denominations also for more

than half a century and then became principally a Congregationalist organ. The American Baptist Missionary union came into being in 1814. The Methodist Episcopal Church created its Board of Foreign Missions in 1819, and other denominations soon took a similar step. The U.S. pattern was to be that of denominational boards of missions through which the denomination officially discharged its missionary responsibility in contrast with the voluntary and unofficial societies of Europe. As the decades passed mission boards and societies, either officially or unofficially representing nearly all the churches, came to exist in Europe wherever there was a sufficient body of Protestants in the United States and Canada, in Australia and New Zealand and in South Africa. By 1900 there were more than 300 such boards and societies, and 60 years later there were more than that number in the United States alone.

Because of the reluctance of the societies to commission women with status equal to that of men and to give sufficient emphasis to special work for women and children, women organized both denominational and nondenominational boards and societies. Examples are the Woman's Union Missionary Society of America (1860), the Zenana Bible and Medical mission (1861) and the Church of England Zenana Missionary society (1880). After general missionary societies gave attention to such work, the women's societies merged with the general agencies or became auxiliary to them.

Nondenominational faith missions, with personnel and funds drawn from individuals and congregations across denominational lines, arose in the second half of the 19th century and became more numerous in the 20th. Unlike the denominational agencies, they promise neither salaries nor fixed allowances to their missionaries, but distribute to them the funds received. There was little difference in theological viewpoint between these societies and the church missions originally, but in the 20th century these faith missions might be characterized as fundamentalist. The prototype and model for faith missions was the China Inland mission, which later changed its name to Overseas Missionary Fellowship. It was founded by J. Hudson Taylor in 1865 in order to carry the Gospel into remote interior regions of China where the older missions had not yet been able to establish new stations.

Wars in Europe and America and economic depressions, such as the great one of the 1930s, might at times curtail missionary support, and local disturbances and major catastrophes like the Boxer uprising might occasionally cause a regional setback; but there was a steady expansion of the missionary force up to mid-20th century. Potent forces in recruitment were the Student Volunteer Movement for Foreign Missions, organized in 1886 in the United States, and the Student Volunteer Missionary union, organized in 1892 in Great Britain.

### Growth of the Churches

The labours of the Protestant missionaries resulted in the gathering of meagre first fruits through much of the 19th century, but toward the end of that century the churches began to grow rapidly. The extent to which mature churches had developed in the 20th century was manifested at the Madras conference in 1938, where half of those present represented younger churches.

**Asia.**—India and China competed for major attention, British societies predominating in the former and U.S. in the latter, and more of the resources of the mission went into India than any other country. William Carey and his associates, Joshua Marshman and William Ward, known as the Serampur Trio, set the pattern for mission work in that country, with an emphasis upon the translation of the Bible, the preparation and printing of Christian literature, schools, and the training of a native ministry. Alexander Duff pioneered in higher education, which became an important medium for introducing Christian principles. A vast system of schools from kindergarten to university was developed. Mass movements from outcaste and low-caste groups were notable.

Ceylon and Burma were closely associated with India in missionary developments, and the types of work were the same. The British societies worked with the Sinhalese and the American Board of Commissioners for Foreign Missions among the Tamils of the Jaffna peninsula. The pioneer in Burma was the U.S. missionary Adoniram Judson, who began work in 1813. The Society for the Propagation of the Gospel came later. Only a small group was drawn from the Burman Buddhists, but large churches were built up among the animistic Karens, Kachins and others. The great Karen Baptist Church proved self-supporting and evangelistic to a remarkable degree from the beginning.

Early missionary ventures in southeast Asia were associated with the Dutch East India company, whose chaplains founded many congregations now more than 300 years old. The Dutch missionary societies made Indonesia the exclusive field of their operations, excepting the Moravian mission in Surinam. The German Rhenish mission also entered and developed the renowned Batak church in Sumatra, the community on Nias, and the church among the Dayaks of Borneo. Many missions worked among the Chinese of the area as long as the Chinese ports were closed to foreigners, but withdrew when the ports were opened. The American Methodists remained to work among the Chinese and also among the animists of British Borneo. In Malaya access to the Malays was denied, and missionary efforts were confined to the Chinese and the later Indian immigrants. The Presbyterian Church in the United States maintained the chief work in Thailand, and the Christian and Missionary alliance was almost alone in Indochina.

In the Philippines the work was carried on entirely by U.S. agencies. When the islands passed under control of the United States, seven boards conferred on the obligation which appeared to rest upon the U.S. churches. Six entered into a comity agreement. During half a century a Protestant community of about 710,000 members and adherents arose. The Philippine Independent Church, with about 1,000,000 communicant members, joined in communion with the Episcopal Church.

China was not open to missionary work until the treaties of 1842–44, and it was a quarter of a century more until toleration was granted. However, Robert Morrison had begun work in Canton in 1807, and he and others like the pioneer Karl F. A. Gützlaff managed to lay the foundation for the vast work to come later. The "protection" afforded missionaries and native Christians by foreign powers did much harm, and local antiforeign movements often caused setbacks. Several hundred westerners and thousands of Chinese Christians died for their faith in the Boxer uprising of 1899–1900.

Protestant schools, literature and hospitals mediated western knowledge; and youths interested in national reform and wanting contact with western culture turned in increasing numbers to these institutions as the revolution gathered momentum. Thus Protestant Christianity exerted an influence far greater than its numbers would have indicated. The churches grew rapidly in the 20th century, and during the war years from 1937 to 1945 indigenous sects not related to the missions began to flourish, such as the True Jesus Church.

As a consequence of Communist government in China all missionaries, except a few in prison or under other forms of arrest, were expelled, and the churches isolated. The church was stripped of all functions but worship and fellowship, and the institutions were taken over by the government. However, there remained considerable evangelistic activity. Much of the leadership of the churches was purged on political grounds, and the churches were put under the corporate direction of a "Three-Self Patriotic Movement" which co-ordinated their activities, marshaled them in support of government policy, and served as their liaison agent with the government.

Following the reopening of Japan and the signing of treaties permitting the residence of foreigners, three U.S. missions working in China simultaneously sent representatives into the country in 1859. Early enthusiastic acceptance of Christianity along with other aspects of western culture ended by 1900 as a strong nationalism began to assert itself. Christianity in Japan is predominantly found among urban and middle classes. Government pressure during World War II resulted in the merger of all denominations into the United Church of Christ in Japan (Kyodan), but after the war some of the churches withdrew. The Kyodan remained the largest ecclesiastical body. Higher education has always been a chief feature of the missionary program, and the

formation of the Japan International Christian university at Tokyo was a notable event after the war.

After several heroic attempts to introduce Christianity into Korea had ended in martyrdom, continuing mission work was begun in 1884 by Henry Appenzeller, Horace N. Newton, and Horace G. Underwood. The Korean churches became renowned for self-support, Bible study and evangelistic zeal. Christianity became under Japanese rule something of a vehicle for the preservation of Korean national aspirations, and Christians were often under great pressure. The Korean War and division of the country multiplied difficulties, but the churches continued to grow.

**Pacific Islands.**—The islands of the Pacific early attracted missionaries, beginning with the London Missionary society's party to Tahiti in 1797. But the vast distances, the thousands of islands and the hostility of many of the native peoples presented formidable obstacles. The roll of martyrs is long, including John Williams and Bishop John Patteson.

**Near East and North Africa.**—Protestant efforts in the near east and north Africa were originally directed toward the Jews and to the revival of the ancient Eastern churches. Education, medicine and literature were emphasized. There were few converts from Islam, and the Armenian and Nestorian Evangelicals in Turkey and Iran were destroyed or expelled after World War I.

**Latin America.**—The Evangelical churches in Latin America were started largely from the United States, although several countries received large Protestant immigrant groups. Brazil has the largest number of Evangelicals; Pentecostals form the largest group in Chile. Two important British missions are the South American Missionary society and the Evangelical Union of South America.

**Africa.**—It is impossible to write anything of consequence in a few lines about the vast continent of Africa south of the Sahara. Although the Moravians began work in south Africa in 1737 and some west African missions were founded in the first half of the 19th century in many parts of east Africa and elsewhere, missionary activity was not undertaken till the 20th century. Missions had to face the problems peculiar to work under a colonial government and later met new problems arising in the African republics. Education has been largely in the hands of the missions, but no university education was introduced. Relatively little was done in raising an adequate ministry for what amounted in many places to a mass movement church. African missions contributed largely to inspiration and support of the whole missionary cause through men like the explorer-missionary David Livingstone and his father-in-law, Robert Moffat.

### Missionary Co-operation

A remarkable degree of co-operation characterized the Protestant missionary enterprise from its beginning. One manifestation of this was the foundation of auxiliary services needed by all across denominational lines, including the Bible societies (British and Foreign, 1804; American, 1816) and the Tract societies (Scotland, 1793; London, 1799; American, 1823). Informal missionary fellowships, of which the earliest was the Bombay Missionary fellowship of 1825, soon became regional and national organizations. India set the example for other areas, and there the regional associations merged into the Decennial Missionary conferences, the first of which was held in Dec. 1872–Jan. 1873. These conferences dealt with recognition, transfer and discipline of members and agents; with common policies; and with the division of territory, which became known as comity. Comity became the general rule except in Japan and it resulted in "denominationalism by geography." Beginning with the negative purpose of guaranteeing noninterference in the affairs of a mission within a recognized area, comity became the basis for positive co-operation and ultimately for the maintenance of union institutions.

Parallel with the conferences in the various fields was a series of international popular conferences in Europe and America. These were New York, 1854; London, 1854; Liverpool, 1860; London, 1878; London, 1888; and the Ecumenical Missionary conference in New York in 1900. Regional conferences were also held in the Scandinavian countries, and a Continental Missions conference met at intervals beginning in 1866. Standing organs for continuous consultation and co-operation among the home base administrators began with the German Ausschuss in 1885 and the Foreign Missions Conference of North America in 1893. These experiments in the field and at the home base led to the World Missionary conference at Edinburgh, Scot., in 1910. John R. Mott traveled around the world on behalf of its continuation committee in order to seek acceptance of the conference's findings and to bring into being national conferences of missionary societies, such as the Conference of Missionary Societies of Great Britain and Ireland, and National Christian councils, in which churches and missions co-operated for common action. These two types of councils and conferences were then brought as daughter councils into the International Missionary council, formally organized at Lake Mohonk, N.Y., in 1921 after a delay caused by World War I. Influential World Missionary conferences were held at intervals by the I.M.C., the first at Jerusalem in 1928. These conferences were occasions for survey, study, shaping policy, devising new strategy, and strengthening co-operation. After the formation of the World Council of Churches (*q.v.*) this body and the International Missionary council entered into formal "association." In Nov. 1961, at the meeting of the general assembly of the World council at New Delhi, India, the two bodies merged, the International Missionary council becoming the Division of World Mission and Evangelism of the World Council of Churches, functioning under a 115-member commission. Thus the world mission of the church was brought into the very centre of the ecumenical movement. (*See* Ecumenical Movement.)

### Orthodox Missions

Missionary efforts by Orthodox Eastern churches during the 19th and 20th centuries were limited to those of the Russian church. Missions were established in Siberia, the Aleutian Islands, Alaska and Japan. The last was founded in 1863 by Bishop Nicolai. Archbishop Innocent founded the Orthodox Missionary society at Moscow to forward these efforts.

Missionary activity ceased with the establishment of Communist control in Russia. Because of its origin, the Orthodox church in Japan suffered severely during World Wars I and II, especially World War II, and was greatly reduced in strength. Assistance was given after World War II by the Russian Orthodox Church in the United States.

### Later Roman Catholic Missions

Roman Catholic missionary efforts had never ceased, although they had reached a low ebb by 1800. They were slow in reviving, but eventually became once more a vast enterprise. The Sacred Congregation for the Propagation of the Faith vigorously directed a world-wide mission, and a new organization came to its support. An Institute for the Propagation of the Faith was formed in Lyons in 1822 for the purpose of raising money for the total work. Eventually a National Society for the Propagation of the Faith, often with diocesan branches, came to be established in most countries where the church is strong. As the result of the crippling effect of World War I on certain European countries, and also because of the growth and power of the Catholic community in the United States, the U.S. churches moved suddenly from the status of a mission field themselves to that of supplying the greatest part of the resources for the worldwide mission. After World War II the preeminent position of the U.S. church was still further enhanced. U.S. missionary personnel remained disproportionately small in comparison with the total body, but U.S. branches of the important missionary orders were organized, and purely U.S. agencies, such as the Catholic Foreign Mission Society of America (Maryknoll, N.Y.), were formed.

The outstanding new development in Roman Catholic missions in the 20th century was the promotion of a native clergy and episcopate, strongly supported by the Roman pontiff (Benedict XV, encyclical *Maximum Illud*, Nov. 30, 1919; Pius XI, encyclical *Rerum Ecclesiae*, Feb. 18, 1926; Pius XII, encyclical *Evangelii Praecones*, June 21, 1951). The movement was given dramatic expression when Pius XI in 1926 consecrated six Chinese bishops

There were more than 100 native bishops, vicars apostolic, and prefects apostolic by the mid-1960s. Moreover, the Sacred College of Cardinals included Asians, Africans and representatives of the middle east and Oceania.

BIBLIOGRAPHY.—A full outline of the history of missions and extensive bibliography will be found in the encyclopaedic work by Kenneth Scott Latourette, *A History of the Expansion of Christianity*, 7 vol. (1937–45). For a general outline of Roman Catholic history separately, *see* Joseph Schmidlin, *Catholic Mission History*, ed. by Matthias Braun (1933). The two great sources for Roman Catholic history are *Bibliotheca Missionum*, begun by Robert Streit and continued by J. Dindinger, and the annual on current literature, J. Romerskirchen and J. Dindinger, compilers, *Bibliographia Missionaria*, published under the auspices of the Sacred Congregation for the Propagation of the Faith (1933 *et seq.*). *International Review of Missions* (quarterly) of the International Missionary Council (1912 *et seq.*) includes extensive "International Missionary Bibliography." For information on current literature *see* the *Occasional Bulletin, Book Notes, Annual Select List*, and special bibliographies issued by the Missionary Research Library of New York city. (RT. P. B.)

**MISSISSIPPI,** often called the "Magnolia state" after its official flower, is a south central state of the U.S. The state is bounded on the north by Tennessee, on the east by Alabama, on the south by the Gulf of Mexico and Louisiana, and on the west by Louisiana and Arkansas from which it is separated by the Mississippi and Pearl rivers. The total area is 47,716 sq.mi., of which 493 sq.mi. are water surface. It is the 32nd state of the union in size. The state capital is Jackson and the state entered the union Dec. 10, 1817, as the 20th state. The magnolia is the state flower and tree, and the mockingbird is the state's official bird. The state flag consists of three equal horizontal stripes, the top one blue, the centre white and the bottom red. In the upper corner of the hoist is a union patterned after the Confederate battle flag. The state motto is *Virtute et armis* ("By Valor and Arms").

## PHYSICAL GEOGRAPHY

**Topography.**—Most of Mississippi, which is situated between approximately 30° 13′ and 35° N., and 88° 7′ and 91° 41′ W., lies within the Gulf coastal plain. Rolling hills cover the greater part of the state except for a narrow strip along the Gulf coast and an area in the northwestern section lying between the Yazoo and Mississippi rivers. These two sections are low and poorly drained. The highest elevation, about 800 ft., is in the northeastern part of the state in Tishomingo county.

**Climate.**—Its latitude, low elevation and proximity to the Gulf of Mexico produce, in southern Mississippi, a rather mild and equable climate, but northward the climate is more subject to extremes. The normal mean annual temperature for the state is 64° F. (about 18° C.); on the coast it is 67° and on the northern border 61°. Annual precipitation for the state is about 51 in. (southern half, 54 in.; northern half, 49 in.). Nearly one-third of the rain falls in January, February and March, but July is also wet. The driest months are September and October.

**Soil.**—The soils along the Gulf coast are generally unsuited to agriculture because of their lack of fertility and poor drainage. A few miles from the coast, however, the soils support tung-oil groves and some vegetable and truck crops.

The loess uplands include an area in the western part of the state that stretches from Tennessee to Louisiana between the delta on the west and the sandy-clay hills to the east. These uplands are made from fine, wind-blown soils that erode easily but are very fertile and productive if cultivated properly.

The delta soils to the west of the loess uplands are rich alluvial soils. Where the problem of flooding has been solved by levees, this is the most fertile area in the state and is noted for its cotton, hybrid corn and rice production. Native hardwoods, such as cypress, red gum and swamp hickories also grow there.

The section lying east of the loess uplands and north of the coastal meadows is known as the "piney woods." This includes most of the southern half of the state. Pine forests predominate in this region and furnish raw materials for the lumber and pulpwood industries.

In the northeastern part of the state, there are two very different types of soil. The so-called "prairie section" is a rich agricultural area which formerly produced cotton, but which now produces livestock and dairy products. Native Bermuda grass is the basis for most of the pastures. The other section in northeast Mississippi is that of the sandy-clay hills. There, the soil is of low fertility and subject to erosion. There are small areas, however, where the soil supports cotton and dairy production.

**Coast Line.**—The coast line, about 85 mi. long, is bordered by a beach of white sand and is broken by several small and shallow indentations, among which are St. Louis, Biloxi, Pascagoula and Point Aux Chênes bays. Separated from it by the shallow Mississippi sound is a chain of low, long, narrow sand islands, the largest of which are Petit Bois, Horn, Ship and Cat. Channels have been dredged so that Gulfport and Pascagoula have become ports for ocean vessels.

**Drainage.**—There are five major drainage basins within the state. The Tombigbee river basin drains the northeastern section. The Pascagoula river, formed by the junction of the Leaf and Chickasawhay rivers, drains the southeastern part. The Pearl river drains the south central section. The Mississippi river and its tributaries drain the western section. The Yazoo river, made by the junction of several small rivers, flows into the Mississippi near Vicksburg thus draining northwest Mississippi. The Big Black river, also a tributary of the Mississippi, drains the west central section.

**Plants and Animals.**—More than half of the total acreage of Mississippi is covered with forests. In the piney woods section of the state the longleaf pine is the most outstanding type of tree. Other types of trees found in the state include the live oaks (often hung with Spanish moss), willow, bald cypress, black and sweet gum, white oak, hickory, honey locust, poplar, maple, sycamore and magnolia. National forests in Mississippi include the Homochitto in the southwestern corner of the state, Holly Springs in the north, De Soto in the southeast, and the Tombigbee, Bienville and Delta.

Mississippi woodlands abound in a large variety of flowering trees, shrubs and plants. Magnolias, dogwood, redbud and wild azaleas, commonly called honeysuckle, are among the commonest varieties of the flowering trees and shrubs. Other native flowers include roses, Virginia creeper, black-eyed Susans, violets, wistaria, papaws and primroses. Improved varieties of azaleas and camellias are grown in gardens in the southern part of the state. Roses, iris and all kinds of flowering bulbs thrive in flower gardens. In March many communities set aside days when gardens are open to the public; the city of Natchez observes the whole month.

Formerly, many wild game animals were native to Mississippi, but uncontrolled hunting eliminated most of them. Game animals now hunted include rabbits, foxes, squirrels, raccoons, opossums and deer. Alligators abound in the swampy bayous. Almost all kinds of freshwater fish are abundant. The most commonly caught are black bass, speckled trout, carp, channel and mud cat, bream and perch; in the Gulf-coast area there are also sheepshead, mullet and drum. Chief among the game birds are bobwhite quail, migratory waterfowl, mourning doves and wild turkeys. Coastal birds include the brown pelican, various types of terns, sandpipers and plovers. Among the songbirds are the state's official bird, the mockingbird, bluebirds, brown thrashers, robins, cardinals, blue jays, warblers and sparrows. In the coastal regions and in the delta the egret is fairly common.

**Parks and Monuments.**—The state has developed a system of public parks most of which have facilities for picnicking, water sports and fishing. There are also accommodations for overnight guests and lodges for assemblies. The state parks contain approximately 14,000 ac. of woodland.

National-park areas in the state are the Vicksburg National Military park and the Natchez Trace parkway. The former was established to commemorate the siege of the city in 1863 during the Civil War. In the park are the remains of trenches and gun emplacements that made up the battle lines (*see* VICKSBURG). The Natchez trace is a road that was developed from an Indian

## VIEWS OF MISSISSIPPI

*Top:* The Mississippi river at Natchez. At the foot of the bluffs is the first lumber mill opened in the state (1809)

*Centre left:* Oystermen at daybreak off the shore of Pass Christian, where there are about 30 sq.mi. of shell fishing banks

*Centre right:* Stanton hall, one of more than 40 historic homes in Natchez, was built in the classic style typical of ante-bellum architecture in Mississippi

*Bottom left:* Connelly's tavern or Ellicott's inn, Natchez, built in 1795 in the Spanish Provincial style

*Bottom right:* Former dumping mechanically picked cotton into wagon in which it will be sent to the gin. Cotton is the chief product of the state

trail which followed the watershed from Natchez northeastward between the Big Black and Pearl rivers to the foothills of the Pontotoc ridge. There it left the divide and struck more eastwardly across the Tombigbee river, meeting the Tennessee river near Muscle shoals. Brices (often Brice's) Cross Roads National Battlefield site commemorates the battle fought June 10, 1864, near the town of Baldwyn. Another national battlefield site is at Tupelo where the last major battle of the Civil War to be fought in Mississippi took place in July 1864. Nearby Ackia battleground, where the Chickasaw Indians defeated the French in 1736, a national monument until 1961, is part of Natchez Trace parkway. Around Natchez are grouped approximately 30 antebellum mansions which are open to visitors in the spring of each year. Other places of historical interest include Beauvoir, the last home of Jefferson Davis, near Biloxi, and Friendship cemetery at Columbus where the idea of Memorial day is believed to have had its origin. The Old Spanish Fort in Pascagoula, now a museum, is considered the oldest building in Mississippi; the old state capitol in Jackson, built in 1839, has been restored and is a museum.

## HISTORY

**The Indians.**—The principal Indian tribes living in Mississippi when the white men came were the Chickasaws, the Choctaws and the Natchez. The Chickasaws lived in the northern part of the state, the Natchez in the southwestern portion and the Choctaws in the remainder. It has been estimated that there were 20,000 or 30,000 Indians living within the present boundaries of Mississippi. At first the white men were most interested in trade and in converting the Indians to Christianity, but later they became interested in settling the area for permanent homes, which brought on conflict.

In the second half of the 20th century, a few Indians still lived in Mississippi on reservations provided by the federal government. Physical remains of the prehistoric Indians, such as arrowheads, pottery and mounds, are still frequently seen. One of the best-known mounds is Nanih Waiya, the sacred mound of the Choctaws, which is located in the southern part of Winston county. Mounds in the western part of the state have furnished artifacts for archaeologists. A group of four mounds near the site of old Selsertown in Adams county has been especially productive in supplying relics.

**Exploration and Settlement.**—In the first half of the 16th century the Spanish began the exploration of Mississippi. The most important expedition was led by Hernando de Soto in 1540. He entered Mississippi near the present site of Columbus and spent the winter near Pontotoc. Early in March 1541 hostility between the Spaniards and the Indians flared into open warfare in which the Spanish defeated the Indians and moved westward to make the great discovery of the Mississippi river in May. Successfully crossing the river, the Spanish passed through parts of Arkansas, Louisiana and Texas. In 1542 the expedition returned to the Mississippi river at a point near Natchez, where De Soto died and was buried in the river. Later the remainder of the expedition made its way to the Spanish settlements in Mexico, but their failure to find any precious metals caused the Spanish to lose interest in the area.

More than 100 years later, explorers went down the Mississippi river from the French colony in Canada. Father Jacques Marquette and Louis Jolliet, a trader, explored the river as far south as the Arkansas river. The accounts given of this trip fired the imagination of René Robert Cavelier, sieur de La Salle, who received permission from Louis XIV, king of France, to explore the Mississippi river valley and to build forts. In 1682 La Salle explored the Mississippi river to its mouth and named the territory Louisiana in honour of his sovereign. The explorer met his death in an attempt to establish a colony at the mouth of the river. His death and the involvement of France in a European war caused a postponement of attempts at colonization.

A successful French colonizing expedition led by Pierre le Moyne, sieur d'Iberville, arrived off the coast of Mississippi in 1699. After the exploration of the lower reaches of the Mississippi river and the coast line, Le Moyne decided to settle on Biloxi bay. There the colonists built a fort and named it Fort Maurepas. In 1702 Fort Louis, on Mobile bay, was established and ten years later Mobile was founded. Soon other settlements were begun near the mouth of the Pascagoula river. The oldest house now standing in Mississippi, called Old Spanish Fort, dates from this period. Fort Rosalie, now known as Natchez, was established in 1716.

The development of French Louisiana passed into the hands of the Mississippi company which was promoted by John Law (q.v.). Law's vigorous policies and the transfer of the colony's capital to New Orleans brought about a rapid development. Trouble arose between the French and the Natchez Indians over ownership of the land, however, and on Nov. 28, 1729, the Indians attacked Fort Rosalie and killed or took prisoner the entire population whereupon the French made preparations to punish the Natchez and their allies, the Chickasaws. The French forces attacked the Chickasaws at Ackia, a village near Tupelo, but were defeated. Continued difficulties with the Indians and unwise administration made the colony unprofitable. When the English won the French and Indian War (1754–63), the French were forced to cede all of their territorial claims east of the Mississippi river, except New Orleans, to England.

The British colony of West Florida included the lands west of the Apalachicola river and those south of the 31st parallel, but later the northern boundary was extended to 32° 28′. Pensacola was the capital, but Mobile the principal settlement. Fort Rosalie, renamed Fort Panmure, was not important until a new wave of immigrants came into the area in the 1770s to escape the unrest on the eastern seaboard. West Florida prospered under British rule, but it was occupied by the Spanish during the American Revolution. When the British signed the treaty of peace with the 13 colonies in 1783, the southern boundary was fixed at 31° though Spain did not recognize this boundary. The area was in dispute until the Treaty of San Lorenzo between the United States and Spain was signed in 1795.

**Statehood.**—The Territory of Mississippi, organized in 1798, included land between the Chattahoochee and Mississippi rivers on the east and west and between 32° 28′ and 31° on the north and south. The Indians held the land to the north. About 5,000 people lived in Mississippi territory at that time. The United States set up a territorial government with Winthrop Sargent as governor and Natchez as the first capital. In 1802 the capital was moved to Washington, a small town near Natchez, and it remained the seat of government throughout the territorial period. An important event that affected the people of Mississippi territory was the Yazoo land fraud by which the Georgia legislature sold to speculators most of the land now making up the state of Mississippi (then a part of Georgia's western claims) in 1795. The following year a new legislature rescinded the sale of the land and in 1802 Georgia ceded the land to the federal government. Other important events of the period were the Louisiana Purchase in 1803 and the War of 1812.

Troubles with the Indians increased during the War of 1812 and Gen. Andrew Jackson was sent to subdue them. By the Treaty of Fort Jackson, Aug. 9, 1814, the Indians were forced to cede valuable lands to the federal government. Mississippi territory was then expanded, but congress decided that the area was too large for one state and divided the territory to make the states of Mississippi (1817) and Alabama (1819).

David Holmes, who had served as territorial governor from 1809, became the first governor of the new state of Mississippi. The early years of statehood brought many changes. In 1822 a new capital, located on the Pearl river near the centre of the state, was named for Andrew Jackson. The United States signed several cession treaties with the Indians: Doak's Stand, in 1820, and Dancing Rabbit Creek, in 1830, with the Choctaws; and the treaty of Pontotoc, in 1832, with the Chickasaws. By 1840 Mississippi had 60 counties, and the entire state was in the hands of white settlers. The state had grown so much that a new capitol building was built and occupied in 1839.

This period of development brought prosperity. Roads and railroads were built, and steamboat navigation played an im-

portant part in getting the ever increasing cotton crop to market. The settlement of new lands and the growing demand for cotton made that crop the most important factor in the economy of the state. Negro slaves were brought in to produce the cotton, and by 1840 they outnumbered the white people.

**Civil War and Reconstruction.**—The period between 1850 and 1860 was marked by an intensive discussion of the slavery question. The Whigs and the Democrats united in support of slavery and its extension into the territories. In 1859 the Democratic state convention adopted a resolution favouring immediate secession if a Republican were elected to the presidency. The Democratic candidate for governor was John J. Pettus, who was elected by a large majority. In the presidential election of 1860 Mississippi voted for John C. Breckinridge, the nominee of the southern wing of the Democratic party.

After Lincoln's election Mississippi took immediate steps to withdraw from the union. A convention which met in Jackson on Jan. 7, 1861, passed two days later an ordinance of secession by a vote of 84 to 15. Mississippi was the second state to pass such an ordinance, and it joined other southern states to form the Confederate States of America. The legislature took immediate steps to prepare for defense, and Earl Van Dorn became commander of the Mississippi troops. Jefferson Davis, one of Mississippi's most distinguished citizens, became the president of the Confederacy.

Many battles and skirmishes of the American Civil War were fought on Mississippi soil, but the most important campaign was the fight for Vicksburg, which involved many months of planning and three campaigns. Gen. U. S. Grant led the third campaign which culminated in the siege and capture of the city (July 4, 1863). (For details of the campaign *see* VICKSBURG.) Federal troops, under the command of Gen. B. H. Grierson, moved across the state from Tennessee to Baton Rouge, La. During this raid, the Federals burned public buildings, destroyed factories and wrecked railroads. Other Federal troops, under the command of Gen. William Tecumseh Sherman, moved across Mississippi from Vicksburg to Meridian destroying property and confiscating livestock and provisions. The war ended in Mississippi when Gen. Richard Taylor surrendered his command on May 4, 1865.

In the summer of 1865 a convention met in Jackson to change the constitution. This convention abolished slavery, but refused to ratify the 13th amendment to the constitution of the United States or to make any changes in the state's voting laws which would enable Negroes to vote. Gov. Charles Clark had already been arrested by federal government troops, and the legislature stayed in session only a few hours because of fear that its members would be arrested. However, there was a political campaign in the fall of 1865. Gen. Benjamin G. Humphreys was inaugurated as governor in Oct. 1865 and served until he was removed by federal troops in 1868. Political conditions were chaotic because the federal congress refused to recognize the government of the state. In 1867 congress put into effect its plan of reconstruction, and Mississippi was placed in the fourth military district. The federal soldiers registered voters who took the oath of allegiance to the union and especially encouraged the Negroes to register. Delegates selected by the newly registered voters framed the constitution of 1869. James L. Alcorn, a Republican, was elected governor in 1869, and Mississippi, after meeting all of the requirements of the reconstruction act, was readmitted into the union. The same year the 14th and 15th amendments to the federal constitution were ratified. From 1870 to 1875 the government was under control of the unscrupulous carpetbaggers, Negroes and that part of the white population that was without political experience. Taxes were increased—expenditures had increased nearly threefold between 1869 and 1871—and there was much official corruption, but the state escaped the heavy burden of debt imposed on some of the other Southern states, by reason of constitutional inhibitions.

Political and economic conditions were very unsettled, and race riots broke out in a few communities. By 1875, however, the Democrats had reorganized themselves and were able to win control of the state legislature.

When the legislature assembled in Jackson in Jan. 1876 impeachment proceedings were begun against the governor, Adelbert Ames; the lieutenant governor, A. K. Davis, a Negro; and the superintendent of education, T. W. Cardoza, also a Negro. Davis was convicted and removed from office, and Cardoza and Governor Ames were allowed to resign. John M. Stone, acting president of the senate, became governor. The Democratic legislature instituted a program of economy and reorganized the government. A constitutional convention drew up a new constitution in 1890 which insured the control of the state to the white people.

**The 20th Century.**—The history of Mississippi in the 20th century has been characterized by progressive legislation. The passage of the direct-primary election law in 1902 placed in the hands of the electorate the nomination of public officials. Reforms were effected in the management of the penitentiary; in care of the ill, the handicapped and the indigent; in transportation; and in the provision of educational opportunities. Politically the state supported the Democratic party in every national election from 1876 until 1948, when the electoral vote went to the States' Rights party with Mississippi's governor Fielding L. Wright as the nominee for vice-president. Democratic again in 1952 and 1956, in 1960 the state's presidential electors, unpledged, voted for Sen. Harry F. Byrd of Virginia, and in 1964 Mississippi voted Republican for the first time since 1872, supporting Barry Goldwater over the Democratic candidate, Pres. Lyndon B. Johnson. The Republicans also elected one representative, the first time in 81 years that Mississippi had sent a Republican to congress.

A new predominantly Negro Democratic party had been organized in the early summer of 1964. Its delegates challenged the seating of the Mississippi delegation in the Democratic national convention. In November, it staged an election in which unregistered Negroes expressed their preference for the Democratic candidate for president.

The Council of Federated Organizations (C.O.F.O.), a civil rights coalition, increased its activity during the summer of 1964. Approximately 850 student volunteers set up community libraries, taught literacy and elementary classes, and encouraged Negro voter registration. The workers found a barrier of suspicion, fear, and apathy among the Negro community and opposition in the white community. There was a resurgence of organizations resorting to Ku Klux Klan methods of intimidation. Crosses were burned, churches were bombed and other methods of terrorism were used. The most tragic event was the murder of three of the volunteers in Neshoba county. The enactment of the Civil Rights law of 1964 increased tension but was followed by what appeared to be a strong movement for acceptance of its provisions.

## GOVERNMENT

Mississippi has had four constitutions in its history. The first was drawn up in 1817 when the state was admitted to the union. The constitution of 1832 was more democratic than the first in that it provided for the election of most of the executive and judicial officers. The third constitution was drawn up in 1869 to make it possible for Mississippi to be readmitted into the union after the Civil War. A fourth constitution was written in 1890.

The 1890 constitution has been amended many times. One of its principal objectives was the establishment of qualifications for voting; these provided that a person must live in the state at least two years and in his election district a minimum of one year before becoming eligible to vote. The prospective voter must also be able to read any part of the constitution or be able to understand it when it is read to him. Voters were further required to register four months prior to an election.

The 1890 constitution also provides that the responsibility for state government should be divided among legislative, judicial and executive departments. The legislature consists of two houses, the senate and house of representatives, both elected for four-year terms. The senate has 52 members and the house of representatives, reapportioned in 1963, has 122 members. The legislature meets biennially in even-numbered years for regular sessions and in special session at the call of the governor.

The judicial system consists of justice of the peace courts,

county courts, circuit courts, chancery courts and a supreme court. There is at least one justice of the peace in each of the five supervisors' districts in every county. Some counties that exceed a specified population have county courts, which have exclusive jurisdiction over eminent domain and juvenile cases as well as civil cases of less importance. The circuit courts are the courts of intermediate or general jurisdiction. They serve as appellate courts for cases from justice of the peace and county courts and hear both civil and criminal cases. The chancery courts are specialized courts which deal with divorce cases, deeds, wills, estates and the guardianship of minors. The number of circuit and chancery courts is fixed by statute. The judges of all these courts are elected for four-year terms.

There are nine judges on the supreme court, which is the highest tribunal in the state and hears cases appealed from the chancery and circuit courts. The state has been divided into three supreme court districts, each with three judges, serving eight-year terms. The member with the greatest seniority is the chief justice.

The members of the executive department who are elected by the people are the governor, the lieutenant governor, the secretary of state, the attorney general, the treasurer, the superintendent of public education, the auditor of public accounts, the commissioner of agriculture and commerce, the tax collector, the commissioner of insurance and the land commissioner. All serve four-year terms and all may immediately succeed themselves except the governor, the treasurer and the auditor. There are more than 100 boards and commissions which administer the state's business. Some of these are elected while others are appointed by the governor with the consent of the senate.

**Finance and Taxation.**—In its early history the state received most of its income from the property tax, but in the 20th century there began a decline in the importance of that tax as a source of state income, though it was still important in financing local governments. Mississippi has a homestead exemption law which exempts homes, not to exceed $5,000 and 160 ac., from taxation. Personal and excise taxes have increased in importance as sources of revenue. Personal taxes include income and estate taxes. Business taxes include franchise taxes, licences, corporation net income taxes and the sales tax. The sales tax provides nearly one-half of the revenue for the general fund.

A state tax commission, composed of three members, has important financial responsibilities. It equalizes tax assessments among the counties, assesses all public utility property, administers the homestead exemption law and collects revenue under tax laws designated by the legislature. These taxes provide 90% of the revenue for the general fund. However, the administration of the revenue system is divided among many agencies.

In the second half of the 20th century, the state's general revenue amounted to more than $225,000,000 annually. Of this sum, slightly more than one-fifth was derived from the federal government. The state's expenditures totaled about $225,000,000 annually, and the gross debt stood at more than $100,000,000. Approximately 33½% of the state's revenue was being spent on education, about 23% on highways, approximately 16% on public welfare and slightly more than 5% on health and hospitals. The state's income was nearly four times as great as it had been prior to World War II. State expenditures had increased about the same amount. Though Mississippi had the lowest per capita income of any of the states, such income was about four and one-half times as great as it had been prior to World War II.

## POPULATION

The population of Mississippi in 1820, three years after it had obtained statehood, was 75,448. Its population ranked 22nd among the 27 states and territories that then composed the union, and was classified as 100% rural. The decade between 1830 and 1840 was the period of most rapid growth after achieving statehood—the population increased 175% during that ten-year span. Immediately before the Civil War, in 1860, the state had a population of 791,305 and was 14th in population size among the 42 units of the government at that time; it was about 97% rural in character. At the beginning of the 20th century, the state had slipped to 20th in rank of population (out of 45 units) with a total of 1,551,270 by the 1900 census. It was still largely rural as 92.3% of the people were classified as nonurban dwellers. From 1910 to 1920 the population declined 0.4% and from 1940 to 1950, 0.2%. The trend continued between 1950 and 1960, there being a 0.04% decline in that ten-year period. In 1940, for the first time in 100 years, the white population (1,106,327) of the state outnumbered the Negro population (1,074,578); in 1960, the preponderance of whites over Negroes had grown larger (57.7% native white, 42.3% nonwhite, practically all Negro).

In 1960 Mississippi had a population of 2,178,141, a decrease of 773 from 1950; it was 29th in population size among the states. The population per square mile in 1960 was 45.1 as compared with 49.6 for the U.S. as a whole. The 1960 urban population was 820,805, or 37.7% of the total, continuing the trend toward increasing urban residence. There was one standard metropolitan statistical area (Jackson; comprising Hinds and Rankin counties; pop. [1960] 221,567). In line with the rest of the U.S. the percentage of persons 65 years old or more was 8.2% in 1960. The percentage of the population 14 years old and over that was in the labour force was 51.1% in 1950 and 51.6% in 1960.

*Mississippi: Places of 5,000 or More Population (1960 Census)**

| Place | Population | | | | |
|---|---|---|---|---|---|

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

In 1870 a uniform system of public education was organized. At that time, each county in the state and each city of 5,000 population was made a district in which free public schools were to be maintained for at least four months of the year under the supervision of a board of school directors. Prior to the Civil War there were no public schools for Negroes, but by 1869 there were more than 80.

With the coming of the 20th century there were many changes in the development of public education. In 1910 the consolidation of schools was begun. At first, wagons, and later, school buses, transported students to school. Colleges began to offer courses in education and two teachers' colleges were established. Schools were graded and standards for teachers were raised. A textbook commission was appointed to select uniform textbooks. In the 1940s the state began buying textbooks for children in grammar and high schools. School buildings were improved and school terms were lengthened.

The legislature of Mississippi embarked upon a new chapter in educational history in 1952. It appointed a recess committee on education whose purpose was to study the public-school system and to make recommendations for equalizing and improving educational opportunities. As a result of its study the committee recommended, and the legislature passed, the necessary legislation for a complete reorganization. A state educational finance commission was created with the purpose of receiving and reviewing plans for the consolidation or reorganization of Mississippi's school districts. The commission could also disburse funds made available by the legislature for school construction and equipment. The plans submitted to the finance commission were drawn up after surveys had been made by experts in school administration. When the reorganization plan was complete, Mississippi had only 151 school districts compared with the more than 4,000 it had had formerly. Negro and white children were in the same districts, but in separate schools. Each county's board of education is elected by vote of the qualified electors of each supervisor's district. The county superintendent of education serves as executive secretary of the county school board.

A system of publicly supported junior colleges grew out of the agricultural high schools which had been started in 1908 to improve educational facilities for rural children. The first agricultural high schools to add junior-college work were Pearl River county and Hinds county in 1922. The popularity of the program led to rapid expansion and in the second half of the 20th century there were 17 junior colleges (14 for white students and 3 for Negroes) to provide educational opportunities beyond the high school. In addition there were four private junior colleges for white students and six for Negroes.

**Colleges and Universities.**—Of the many colleges established in Mississippi before 1860, two were still in existence in the second half of the 20th century. Mississippi college at Clinton (affiliated with the Baptist Church), established as Hampstead academy in 1826; and the state University of Mississippi, chartered in 1844 and opened in 1848 at Oxford. Other state-supported schools for white students are Mississippi State university (1878) at Starkville, Mississippi State College for Women (1884) at Columbus, University of Southern Mississippi (1910) at Hattiesburg and Delta State college (1924) at Cleveland. For Negroes there are Alcorn Agricultural and Mechanical college (1871) at Lorman, Jackson State college (1877), which became a four-year degree-granting tax-supported institution in 1940, at Jackson and Mississippi Vocational college (1946) at Itta Bena. Among the privately supported four-year colleges for white students are Belhaven college (Jackson, Presbyterian, 1894), Millsaps college (Jackson, Methodist, 1891), William Carey college (Hattiesburg, Baptist, 1906) and Blue Mountain college (Blue Mountain, Baptist, 1873). A private senior college for Negroes is Tougaloo Southern Christian college (Tougaloo, Congregational Christian and Disciples of Christ, 1869). A scholarship program is financed by the state for Negro students who need to go outside of the state for additional training that the state does not provide.

In 1962, following refusal by Mississippi authorities to obey a federal court order to admit James Meredith, a Negro, to the University of Mississippi, Meredith enrolled in the school under the protection of U.S. marshals. Rioting, which broke out on the campus and in nearby Oxford, was quelled only by the intervention of U.S. army troops and units of the federalized Mississippi national guard.

## HEALTH AND WELFARE

The Mississippi state board of health was organized in 1877, but it did not become an important factor in public health until the 20th century, when the legislature increased its support and expanded its facilities and duties. The board's educational program has been effective in the control and eradication of communicable diseases.

The state's hospital program includes hospital licensing, the allocation of funds to, and the inspection of, hospitals that care for charity patients, and hospital planning as well as construction. The state also provides hospitals at Laurel, Meridian, Natchez and Vicksburg for the care of the indigent. The University hospital, at Jackson, also provides care for such patients. The state sanitorium near Magee provides for tuberculosis patients.

After the Hill-Burton act was adopted by the federal congress in 1946, the Mississippi commission on hospital care formulated a complete plan for hospital construction in the state. These new hospitals and health centres were financed by federal, state and local funds. Within ten years the number of available beds had increased 55% and hospital admissions 117%.

The state legislature established the department of public welfare in 1936 with funds provided by the federal and state governments. The department, operating through the county welfare departments, provides assistance to the indigent aged, the physically disabled, dependent children and the indigent blind. Blind children can be sent to state schools for the blind and there is also a college fund for the aid of the blind. The state also maintains schools for the deaf. The state cares for its mentally retarded at the Ellisville state school and for the mentally ill at hospitals in Meridian and Whitfield.

The department of public welfare supervises probationers; that is, children who have appeared before juvenile courts but were not sent to a training school. Mississippi maintains two training schools for delinquent children, one at Columbia for white children and the Oakley training school, near Raymond, for Negro children.

The Mississippi state penitentiary at Parchman operates farms and shops to provide for the needs of the penitentiary. It also provides vocational training as part of its rehabilitation program as well as an elementary education for those who need and want it.

## THE ECONOMY

**Agriculture.**—Throughout its history Mississippi's economy has been based upon agriculture. Although the percentage of agricultural workers was decreasing, about one-half of the total working population was still employed on the farm in the second half of the 20th century. Cotton has always been the most important single crop, but in the 20th century the boll weevil threatened to destroy the cotton economy. This threat was met by the development of improved varieties of cotton seed and the use of insecticides. The increased use of machines, such as tractors and cotton pickers, and improved agricultural practices also helped cotton maintain its dominance. The value of the cotton crop has been materially increased by the use of the seeds for the manufacture of cottonseed oil and feed. Nevertheless, in spite of these improvements the harvested acreage of cotton has gradually decreased over the years. The production of livestock and livestock products has increased so that they rank next to cotton in cash income. Other crops include hay, soybeans, and corn.

**Industry.**—In the 1930s the state started the "Balance Agriculture With Industry" (B.A.W.I.) plan to promote the development of industry. Under this plan communities gave financial aid to new industries. Such industries were so located that approximately a third of the nonagricultural workers were employed in manufacturing. Since more than one-half of the area of the state is classified as forest lands, it is natural that the manufac-

ture of wood and wood products is the most important industry. After World War II the manufacture of clothing became one of the fastest growing industries. Other important manufacturing industries include food processing, chemicals and textiles.

Electricity furnished by the Tennessee Valley authority has been an asset in the industrial development of northeast Mississippi.

**Minerals.**—Oil and gas are the principal minerals found in Mississippi. In addition to the gas wells within the state, gas pipelines from Louisiana and Texas cross Mississippi making natural gas easily available to a large percentage of the population. Gas extraction plants located in the Cantield and Brookhaven fields produce gasoline and butane and propane gas.

The oil industry had its beginning in 1939 when the Tinsley field in Yazoo county was discovered, and within 20 years there were more than 2,000 producing wells in the state. More than one-third of the land is under lease for oil and gas development. Refineries produce gasoline, kerosene, fuel oil, lubricants and asphalt.

Other natural resources include sand, gravel and limestone suitable for the manufacture of cement; and clay and clay minerals, including deposits usable in the manufacture of brick, tile and pottery, bentonite and fuller's earth.

**Transportation.**—The Mississippi river is one of the most important routes of transportation within the state. The United States government improved navigation on the river by dredging the channel, by providing navigation aids and by flood control. Coal, steel, grain, automobiles, sugar and oil are the principal commodities carried by river freight. Greenville, Vicksburg and Natchez are the leading river ports.

Railroad construction began in Mississippi in 1831 when the first line connected Woodville with St. Francisville, La. At the time of the Civil War, there were two east-west lines and two north-south lines across the state. There was little new construction after the war until the rise of the lumber industry in the early part of the 20th century stimulated the construction of additional lines. The coming of motor transportation and improved highways, however, caused some rail lines to be abandoned.

In 1930 the state highway system was placed under the control of a highway commission. The state built and maintains a primary system of highways which includes the main highways across the state. A secondary system of hard-surfaced farm-to-market roads affords good transportation to the rural areas.

Commercial airplane transportation first came to Mississippi in 1929 when passenger service was begun from Dallas, Tex., to Atlanta, Ga., via Jackson. Later, another route from Chicago to New Orleans also stopped in Jackson. These flights made Jackson an important airport. The Gulf-coast area is served by flights from New Orleans to Jacksonville, Fla. Local service lines operate within the state and provide travel by air between principal cities.

**MISSISSIPPI RIVER,** the "Father of Waters," was named Mishipi by the Ojibwa Indians (*Mis*, "great"; *sipi*, "river"). On some of the early French maps it was so named, and it is eminently deserving of the name. The source of the river was not known until 1832, when Henry Rowe Schoolcraft discovered its origin in a lake he named Itasca (Lat. *veritas*, "true"; *caput*, "head"). (*See* ITASCA, LAKE.) In this northern Minnesota lake district, 1,475 ft. above sea level, three great river systems, the Red, St. Lawrence and Mississippi, have their origin.

The length of this great river can only be approximated due to imperfect drainage in the north and meanders in the south; the U.S. department of the interior, geological survey, gives it as 2,348 mi. The least accurately measured portion is from the mouth of the Ohio to Head-of-Passes below New Orleans, where for 954 mi. the Mississippi flows over land of its own making. The greatest fall in the river is in the 500-mi. stretch upstream from Minneapolis-St. Paul, a drop of 700 ft.

With its two great tributaries, the Ohio and the Missouri, the Mississippi drains an enormous area; water from 31 states and two Canadian provinces flows into the Gulf of Mexico by way of this system. This embraces approximately 1,243,700 sq.mi. or one-eighth of all North America. Expressed another way, its longitudinal expanse is 1,900 mi. and its latitudinal 1,400 mi.

Physiographically the Mississippi drainage basin embraces parts of the Laurentian, Central lowland, Great Plains, Appalachian and Central highlands, Rocky mountains and Gulf coastal plain provinces. Climatically it also includes a diverse group: from humid continental short summer in the north to humid subtropical in the south; from humid continental long summer in the east to steppe and mountain in the west. Mineral endowment and soils represent a similar diversity.

The Mississippi empties into the Gulf of Mexico an estimated 724,000,000,000 cu.ft. of water each year. This is about 1½ times the discharge of the St. Lawrence, 5 times that of the Rhine and

AERIAL VIEW SHOWING THE CONFLUENCE OF THE MISSOURI AND MISSISSIPPI RIVERS A FEW MILES NORTH OF ST. LOUIS. THE MISSOURI IS THE MUDDIER RIVER SHOWN ENTERING THE MISSISSIPPI RIVER FROM THE LEFT

177 times that of the Thames. The Ohio is the greatest contributor to the water of the Mississippi, being about 3½ times that of the Missouri, the next greatest. It is not necessary to view the waters from the air to see that the silt in the Missouri identifies its contribution for miles downstream.

**Tributaries.**—One way of evaluating the Mississippi's contribution to American life is to examine its tributaries. The Mississippi may be resolved into three major regions—headwaters and northern tributaries; the very large tributaries of the middle section; and the lower Mississippi—each region with its distinctive characteristics. For a time during the days of early settlement, the river was a bond that tended to unify these physical regions, but with the westward movement and an occupied continental heartland, the uniqueness of the three tributary regions asserted itself in the character of river use; the unifying effect of the river began to increase again after 1940.

**Northern Region.**—Except in southwestern Wisconsin, the headwaters and northern tributaries flow through an area of comparatively recent release from the continental ice sheet; much of the character of drainage and soil derives from this fact. Physiographically it is essentially the West lakes section of the Central lowland and the Superior upland portion of the Laurentian shield. The prevalence of lakes of all sizes and swamps, plus the fact of flow over a plain of alluvial fill, gives a meandering course to the headwater streams and even to the upper Mississippi itself. The lakes and swamps also greatly reduce the number and stage of floods and limit the usefulness of streams to local commerce.

The larger tributaries from the east are the Wisconsin, Black, St. Croix and Chippewa, names redolent with memories of upper lakes' lumbering. There is but one major tributary from the west, the Minnesota. The better lands of the basin lie to the west, but there are none of the minerals that figure so prominently in the east. The level plains of old Lake Agassiz support an important grain-livestock economy. On the upper Mississippi and its northern tributaries are extensive areas of marshland that support a specialty crop, wild rice, the harvest of which is largely in the hands of Chippewa Indians (who serve as guides or lumbermen for the remainder of the year). Over much of the area there are the marks of three successive exploitations: lumbering, mining and generally subsistence farming.

**Middle Region.**—The middle section of the Mississippi drainage basin is the region that gives the basin its continentality. Two great river systems, the Ohio and Missouri, embrace very extensive areas to the east and west, respectively. This section of the Mississippi and the tributaries has virtually none of the youthful landscape characteristics noted in the headwaters. The river is more deeply entrenched, with the banks generally no more than a mile apart; the names of some of the towns and cities—Council Bluffs, for instance—suggest this.

Tributaries from the east include such important streams as the Rock, Illinois and Kaskaskia; from the west come the Cedar and Des Moines rivers. In considering the apparent paucity of tributaries in this section, it must be remembered that both the Ohio and the Missouri are great river systems, each with many important tributaries.

The middle section of the Mississippi is much more subject to flooding than the northern, owing in part to the absence of lakes but mostly to the rainfall distribution and percentage of runoff of its far-flung eastern and western tributaries. There the Rockies and the Appalachian and Central highlands introduce an entirely different reason for changes in the volume of water moved by the rivers; the timing of their floods can be disastrous to the lower Mississippi river plains. The accessibility of this portion of the Mississippi river valley is one of the three bases of its economic dominance. East of it lie the lower Great Lakes and St. Lawrence river, the only deep-water outlet to the Atlantic; to the east also are the important corridors through the north and Appalachian highlands that give access to the middle Atlantic port cities. Far to the west are the passes through the Rocky mountain barrier. South of it is the route to the Gulf of Mexico, oldest and most important of the water outlets for the heartland of the United States.

**Southern Region.**—The southern portion, below the confluence with the Ohio, has tributaries that differ markedly from those of either section of the river to the north. For almost a thousand miles, the Mississippi, swollen by the waters of the Ohio, pursues a meandering course over its flood plain built upon the underlying coastal plain. As in no other part of the river valley, it may be characterized by its tributary river basins, which tend to parallel the Mississippi itself. From the north they are the St. Francis, Yazoo and Tensas basins, with the Yazoo as the only major eastern tributary; and the Atchafalaya, which was made a distributary. The St. Francis, Yazoo and Tensas basins virtually monopolize the tributaries of the main stream; the major exceptions are, from the west, the Arkansas and Red, two of the longest tributaries to the lower Mississippi.

A third drainage feature is the series of short placid Louisiana streams, which, at least in times of high water, act as distributaries of the lower Mississippi. Among the larger ones are the Teche and La Fourche.

1. Yazoo Basin. In the southern region, longest of the three, the features common to the four parallel tributary basins are far greater than those that distinguish one from another. The only important tributary basin to the east of the Mississippi is the Yazoo, lying between Memphis and Vicksburg. The Yazoo river follows a very meandering course on this alluvial plain, with a fall of only 7½ in. per mile or about twice that of the Mississippi a few miles to the west. Prior to the completion of the system of levees in 1886, the Yazoo basin was subject to overflow by the larger stream; after that time it became one of the major cotton-growing regions in the south.

2. St. Francis Basin. The St. Francis is the northernmost and largest of the alluvial basins on the west side of the Mississippi; the Black and St. Francis rivers follow nearly parallel courses along the major axis of this basin. The southern end of the basin is hard to determine since the Arkansas flows in from the Rockies and merges its alluvial plain with the St. Francis as it makes its difficult entry into the Mississippi. In most respects the St. Francis basin is similar to the Yazoo, although interrupted by Crowley's ridge.

3. Tensas Basin. The Tensas basin comprises the flood plain on the west side of the Mississippi from the Arkansas to the Red river. It, too, has a vaguely defined southern boundary where it merges with the flood plain of the Ouachita river coming in from the Ozark highlands. In all essential respects, this basin is similar to the Yazoo. The long Red river, which makes a doubtful entrance into the Mississippi, has a very low gradient, much silt and a number of meandering tributaries on both sides. Several of these tributaries long ago were dammed by logs to form lakes of varying sizes; its waters merge with the Atchafalaya river on the south.

4. Atchafalaya Basin. The fourth and final alluvial basin is that of the Atchafalaya, west of Baton Rouge and New Orleans. While similar to the other three alluvial basins of the lower Mississippi, this river was naturally an independent stream; engineers made it a distributary of the Mississippi to use when the need arises in times of flood.

**Use.**—Earliest to discover the low divide separating the Mississippi from the Great Lakes and to evaluate the usefulness of the river were the French from the St. Lawrence valley, whose fur traders, traveling with a priest, started many Mississippi valley villages before the English appeared. Among them were: Peoria, 1680; Detroit, 1701; New Orleans, 1718; and St. Louis, 1764. Ohio was the only state in the old Northwest Territory with no French land claims at the time the public domain was established. In a sense the French were not true colonists since their economy never passed the fur-trading dominance; fur trade tends to discourage the evolution of a permanent economy. To these French trappers, the river was the final link in the St. Lawrence-Great Lakes-Mississippi waterway to the warm Gulf of Mexico and the Caribbean. They recognized its geographical advantage and unifying influence in terms of continental development, but they were numerically and economically inadequate to secure and hold it. After the treaty of Paris in 1763, French

settlements in the St. Lawrence valley became part of the British North American colonies.

The British tidewater colonies along the middle Atlantic coast were forbidden to expand westward across the Appalachian highlands into the Mississippi valley by the British North America act. To the American continental congress and its successors, the Mississippi river was at first a threat and then an invitation; the purchase in 1803 of the Louisiana territory ended the threat. Lacking the power to protect lives or land titles in the old Northwest territory, the nation's first public domain, the continental congress forbade settlement in this part of the Mississippi valley; after enactment of the ordinance of 1787, however, settlement was permitted. This territory developed into the nation's first corn and wheat belt; it soon found a ready market for its surplus farm products in the old cotton-growing south. The Mississippi's big eastern tributary then gathered the commodities for shipment down the Mississippi; until the Civil War peak of steamboating, commerce on the Mississippi grew rapidly. By 1840 one-half of all commercial vessels under American registry were in use on the Mississippi river system. After the Civil War, steamboat traffic declined; the railroads gave better service.

The emergency in transportation incident to World War I resulted in such rail congestion that the federal government attempted to stimulate river transport; the cessation of hostilities did not end this effort. The Federal Barge Lines were established in 1918 to demonstrate the economy of barge traffic; 40 years later, river barge traffic had grown so spectacularly on all parts of the Mississippi system that the Federal Barge Lines were sold to a private carrier.

**Improvements.**—Factors accounting for the increase in traffic on the Mississippi are many and varied. Improvements in the river and in transportation equipment lagged prior to 1928, but thereafter, and especially after World War II, great strides were made. The process of levee maintenance, straightening of the channels, desilting, devices for flood alleviation (if not always control), and dredging of channels, especially below New Orleans, have always been in progress.

Most Mississippi locks, like those in its busiest tributary the Ohio, measure 600 ft. by 110 ft., making double locking necessary. The Falls of St. Anthony (Minneapolis-St. Paul) are bypassed by canals constructed by the corps of engineers. The lower lock is 1,200 ft. long and has a rise of 25 ft.; the upper lock has a rise of 50 ft. (highest on the river). This particular lock illustrates a significant change in river improvements, a change that attempts to integrate river transport with the recentralization of the nation's manufacturing. Above the upper lock a harbour 3½ mi. long was constructed to serve the commerce of and through the Twin Cities. Adjacent to the harbour a 3,000-ac. tract of reclaimed land was developed to serve as an "industrial park" for newly located factories.

Farther south, New Orleans constructed an industrial canal linking Lake Pontchartrain with the river and offering planned industrial sites for new factories. St. Louis built a terminal for river traffic, with the result that tonnage handled nearly tripled between the late 1940s and late 1950s. Near Keokuk, Ia., the locks are 1,200 ft. long, 110 ft. wide and 38 ft. deep, a type planned for all locks subsequently constructed.

Improvements in towboats and barges proceeded more rapidly than did river facilities. Specialized barges were developed for certain commodities—molten sulfur, petroleum, new automobiles, acids and alkalis—and the size of barges, power of towboats and aids to navigation also increased. A barge 300 ft. long holds 1,000,000 gal. of petroleum; a railroad tank car holds 13,000 gal. An oil-fired, air-conditioned excursion steamer carries 4,000 passengers. A St. Louis firm built a towboat with diesel engines generating 8,500 h.p., ten rudders and five decks carrying a crew of 17; it could move 40-barge tows from St. Louis to New Orleans in ten days at rates, depending upon the commodity, from 12% to 50% lower than railroad rates. Such a tow moves more than twice the tonnage of most ocean freighters. Not many of the 4,200 modern diesel towboats on the Mississippi river system are as large, but the trend is upward. Approximately 8% of intercity freight is moved over these waters.

Manufacturing industries began to be attracted to Mississippi river sites, particularly after World War II. In this choice of location, though improvements in the river were influential, the prime factor was expanding markets and rising freight costs. These industries consume a diversity of raw materials and produce a variety of commodities, but the most important, perhaps, are those that require much power in processing. In the south the chemical industries have come to dominate the Intracoastal waterway, which contributes much tonnage to commerce on the Mississippi above New Orleans. St. Louis, Memphis, Baton Rouge and New Orleans have all become important manufacturing cities, each with a wide market area. Among the smaller cities that might be named are Dubuque, Davenport, Vicksburg and Chalmette.

**Problems.**—It is to be expected that there will be problems connected with the regular use of such a large river as the Mississippi. Some of these problems, in fact most of them, stem from the physical circumstances of the river; historically, there are the difficulties of using the Mississippi as a boundary between states. The changing course of the main channel is a periodic problem for counties and states, particularly in the southern third of the river, though some stabilization has been achieved.

Floods have always been a very serious problem, not only to navigation on the river, but to riparian occupance as well. Experience since the early 19th century, together with the findings of the Waterways Experiment station operated by the federal government near Vicksburg, resulted in a vast system of river controls and harbour improvements. Aside from the flood control measures established on tributary rivers (for instance, the Tennessee Valley authority, Miami Valley Conservancy district and Missouri Valley authority), the several Mississippi engineering districts constructed a complex pattern of reservoirs, floodways, spillways, distributary channels and levees in the lower third of the river system.

Despite these improvements, the regular commercial use of the Mississippi is attended by serious hazards. Ice and high water are perennial problems. Channels shift and bars are formed. The river functions as a commercial artery only if dredging is constantly underway at several points, notably in the channels below New Orleans. The devices for reducing flood damage in themselves give rise to risk of property damage.

The chief economic problem centres around financial support of river navigation, flood control measures, etc. The channel is maintained and lighted, levees are built, locks are operated and personnel are licensed at federal expense; only the transportation equipment is taxed. Even on the busiest river of the Mississippi system, the Ohio, if the hidden costs are considered, traffic is partly subsidized by the tax-paying public.

**MISSISSIPPI RIVER STEAMBOAT.** Few phases of 19th-century North American life had so wide and vivid an influence on the region and people around it as the Mississippi river steamboat. For 50 years, from about 1820 to 1870, this "swimming volcano," as one passenger called it, dominated the economy, agriculture, commerce and social customs of the middle area of the United States.

These "palaces on paddle wheels" made possible the golden age of the central south and Mississippi valley during the days before the Civil War. They gave its greatest growth to New Orleans, queen city of the Mississippi, and determined the direction of development of other cities, towns and rural areas. They made fortunes for their owners and for plantation masters; they brought

much of the old south in touch with the world and aided in the growth of slavery and the cotton economy.

In a region still not far removed from its frontier period, the steamboats provided a primary contact with other people and other ways of life for thousands of men and women. They gave to American tradition such figures as the waistcoated Mississippi gambler, the Negro roustabout who dragged cargoes on and off, and emotion-charged incidents such as the bizarre explosions on the river and the great Mississippi races.

Steamboat pioneering began in America in 1787 when John Fitch of Connecticut made a successful trial. Robert Fulton's profitable experimentation followed, but not until 1811 was a vessel built especially for the "western waters," the lower Mississippi—the "New Orleans," built at Pittsburgh, Pa., under the direction of Nicholas J. Roosevelt, agent for Fulton and Robert R. Livingston. Most observers predicted disaster when Roosevelt, with his wife, started down the Ohio. The way was dangerous and the Mississippi an especially hazardous stream, with eddies, rapids, hidden snags and sand bars.

The trip began in May and did not end until Jan. 10, 1812. The vessel had many difficulties, again and again it tied up for repairs. After traversing the Ohio falls it continued downriver; at New Madrid, Mo., a violent earthquake made the earth open and river banks crumble away, but the "New Orleans" survived. After wild excitement at many points, it arrived at the Creole city.

There Fulton and Livingston began in early 1812 the operation of a service between New Orleans and Natchez, Miss., under a monopoly contract with the territory of Orleans, one of a number of such contracts obtained in various states. The vessel traveled eight miles an hour downstream, three miles up. Within two years the "New Orleans" sank, though her engine was rescued. Fulton and Livingston continued operations in this western area, but the former wrote soon afterward of his weariness and disgust at the expense and losses.

Nevertheless J. G. Flügel, an observant passenger on a second "New Orleans" steamer of 1817, described the "elegance" of the boat, with "red bombazette curtains and fringes and mosquito bars," sofas, chairs and looking glasses. Despite Fulton's gloomy remarks, Flügel claimed that on one such Natchez-New Orleans trip net proceeds reached $4,000. "There is within the bounds of knowledge," he asserted, "no business in any part of the globe which is more lucrative than this . . ." ("Diary of J. G. Flugel," *Louisiana Historical Quarterly*, published by the Louisiana Historical Society, July 1924.)

Yet the Mississippi remained a treacherous stream. In 1816 Henry Miller Shreve of Shreveport, La., made history by launching his "Washington"; before long it made the trip from New Orleans to Louisville in a phenomenal time of 25 days. In so doing Shreve flouted the Fulton-Livingston claim to an exclusive right to navigate the river. For several years the two sides fought the matter in courts, and eventually the monopoly was rejected there.

Shreve's work has given him the title of father of Mississippi navigation. An engineer-boatman-inventor, he had realized that vessels planned for clear, deep eastern waters would never do well on the Mississippi. He made radical changes in design; drawing up the engine, he mounted it on a hull as shallow as that of a barge. The engine itself was high pressure, capable of making progress against the Mississippi's might.

A tall second deck was added and paddle wheels placed at the side. Though many hooted at the strange-looking thing, so tall in the air, so light in the water, Shreve's experiment became the prototype of all Mississippi steamboats.

From then on the people of the Mississippi valley and tributaries turned to the steam vessels. In 1814 New Orleans, near the mouth of the river, had counted hardly 20 steamboat arrivals. Within 20 years the figure had reached 1,200. Cotton was spreading over the south and southwest; sugar had become the major crop of the area below New Orleans. For the south a new day had begun.

About New Orleans the steamboat-cotton wealth was crystallizing. By the 1830s its banking capital exceeded that of New York city; its port competed with New York as the nation's largest, and in exports it frequently ran ahead of its eastern rival. In a single decade New Orleans' population doubled.

Upriver the steamboats brought soaring prosperity to Memphis, Tenn., St. Louis, Mo., Natchez and other points. Along the Mississippi and its tributaries the roads were short and undependable; the rivers were the highways of the day and they ran south to New Orleans and the ocean below it. "The master street of the world," one enthusiast called the New Orleans water front; nowhere else, it was said, could be found such a concentration of steamboats. They stretched for four or five miles, curving with the river itself, sometimes two and three deep.

Lady Emmeline Wortley described the procession of the river boats on the lower river: "By night the scene is one of startling interest and magical splendor. Hundreds of lights are glancing in different directions from the villages, towns, farms and plantations on shore, and from the magnificent 'floating palaces' of steamers, that frequently look like moving mountains of light and flame, so brilliantly are these enormous leviathans illuminated, outside and inside . . . steamer after steamer coming sweeping, sounding, thundering on. . . ." (Lady Emmeline Stuart Wortley, *Travels in the United States*, Harper & Brothers, New York, 1851.)

Vessels grew larger, engines more powerful, paddle wheels bigger. The double smokestack became the symbol of the steamboat, and between them many a boat carried a gilded ornament or a flamboyant design of some kind—a cotton bale, a star, an anchor. Paddle boxes had their own ornamentation. Inside all might be white "gingerbread," wood curlicued and gilded, knobbed and flowered. Eventually exteriors were similarly trimmed until, as more than one person noted, they looked like wedding cakes afloat.

All steamboats of any size ultimately had "lounges" or central cabins in the style of ornate hotel lobbies, with rich rugs, oil paintings and lines of chandeliers. Chefs were taken from famous restaurants and had large staffs to assist them. A number of boats had large orchestras, and there were maids and butlers to assist cabin passengers. Surviving menus show scores of dishes, with choices of as many as 7 soups and 15 desserts. Now and then a vessel printed its own newspaper as it went up and down the river. For the men there were bars, long and mirrored and almost always jammed, barber shops and lounging quarters.

Eliza Ripley in her *Social Life in Old New Orleans* tells how one imaginative owner decorated stateroom doors (and flattered particularly good steamboat patrons) with views of some of the great plantation homes along the Mississippi. Nevertheless, Mrs. Ripley makes clear that, with all the display, such trips might be arduous. On the popular "Grey Eagle," berths were so narrow that, in trying to turn over, she fell out and landed in the washbasin on the opposite side. Her sister, sitting on the lower berth to braid Eliza's pigtails, "then sent me forth so that she could braid her own." Service proved negligent, meals confused and disorganized.

Outside the cabins a simpler, rougher life went on. Roustabouts and crew stretched on the decks, and with them deck passengers

PADDLE WHEEL STEAMBOAT

who might be poor traders trying to sell wares in the hinterlands, new settlers and their wives, immigrants from Europe or flatboatmen going upriver. (The latter continued to flourish for downriver trips, in spite of the arrival of steam power.) In the social caste system of the south such passengers received little heed and almost no care; they sat or lay wherever they could.

The captain became an omnipotent person, a man with vast authority over life, commerce or well-being. He could remove a passenger at a word, and tales are told of luckless ones dropped at marsh edges. He lived in splendour on land and water, often a man of many anecdotes, perhaps of prodigal hospitality when in good mood, but of sulfurous rages and thundering orders when others crossed him.

The steamboat pilot was a man deferred to by all on board, including the captain. He received top pay, and generally deserved it. On him depended the safety of passengers and crew, day and night. His was a rare ability, part long training, part detailed knowledge of an unbelievably complicated subject, part a quality approaching instinct.

The Mississippi remained treacherous, filled with snags, with driftwood, with shoal points just below the surface. Perched high above the steamboat, the pilot operated in darkness, depending on memory, on years of accumulated skills and on informed guesswork, for the river changed constantly and the pilot had to take chances at every point.

Mark Twain (Samuel Clemens) in his *Life on the Mississippi* has an inspired, often-quoted description of his interview with a pilot, while a cub on the river. Clemens was told he must "get this entire river by heart . . . know it just like ABC. . . . It is all there is left to steer by on a very dark night. Everything else is blotted out and gone." (*Life on the Mississippi*, Hillcrest ed., *The Writings of Mark Twain*, vol. ix, Harper & Brothers, New York, 1904.) Moreover, the cub had to learn that on a clear starlit night black shadows had special qualities that must be understood and that a certain line on the surface meant an obstruction, while another only a wind. But how could he know the difference? His teacher could not explain precisely; Clemens must watch and learn. It was no wonder that the cub said, at one point, that he wished he were dead. He later became an expert, however.

The blowing of the steamboat whistle, signaling an approach to a town, could electrify a river community. Hundreds would race to the riverbank to watch the excitement, to see who arrived, what news the crew brought, how high the cotton bales towered on the deck. (Sometimes the cotton filled every foot of space, blotting out light from cabin windows, so that candles had to be used by day.) The steamer carried foodstuffs and manufactured goods; it took produce and materials for transshipment.

At other points hundreds watched the procession of the steamboats. Since the engines swallowed fuel hungrily, men cut down vast supplies of cordwood and stacked them for quick pickups when needed. At isolated spots, tiny settlement points or the edges of plantations, individuals or clusters also stood on the banks for hours with flares to await the next vessel. Most steamboats would halt anywhere for business, even performing casual errands.

Smaller vessels, the showboats, were also moving along the Mississippi and tributaries with plays and vaudeville, little companies of entertainers with a staple line of melodramatic favourites. The showboats made their greatest successes at towns which had no other theatre. About them, as about the steamboats, went colonels, ministers, lawyers, prostitutes, thieves, schoolgirls, housewives—a cross section of the population of the day.

Repeatedly stories were whispered of well-dressed individuals, soft-mannered, hard-eyed, who struck up acquaintances with young travelers or others new to the river. After a few minutes at the bar the conversation went to cards; a game followed and in the morning the river gambler might leave with $10,000, a year's plantation profits. Other accounts describe games that went on for 36 or more hours, whole estates being lost by the lift of a card. Some gamblers operated singly, others in pairs, many maintaining that they operated "fairly and honestly."

The average life span of a vessel was four to five years. Not built to last long, the vessels' engines sometimes were poorly constructed and maintained, and the steamboats fell victim to obstructions in the river, to exploded boilers or mishandling in the engine room—or simply the yearning for speed. Time schedules constantly quickened. In Shreve's day the New Orleans–Louisville run was 25 days; in 1853 the "Eclipse" shortened it to less than 4½.

From 1810 to 1850 an estimated 4,000 persons died in steamboat disasters. Classic accounts describe the drowning of scores, the hurling of bodies across banks; many lingered on, horribly burned, others were never found. A large proportion of such disasters could be traced to the custom of races on the river. Captains of two vessels leaving a city about the same time or meeting in the river, would frown and shout at one another; from crew and passengers a cry would go up, "Beat 'm!" From then on hysteria would seize men and women. Shouting, waving, they would stare intently as one, then the other took the lead.

Safety precautions would be flouted, engines pushed beyond capacity, and then tragedy sometimes followed. Again, however, such races were also carefully prearranged, with thousands learning of them in advance and looking on from shore. The winning vessel would gain a new popularity, a great commercial advantage, if it survived.

Meanwhile, little heeded by the proud steamboat interests, two potent rivals were in the making. Railroad construction began early at Baltimore, Md., in the upper south, with the launching of the Baltimore and Ohio railroad in 1828. Bad times of 1839, however, deterred other large-scale southern railways, and along the Mississippi leaders scoffed at the new medium. Canal construction also started in 1828, between Baltimore and Cumberland, Md., yet few river people saw a reason for concern. Nothing could be faster or cheaper than the steamboats, they insisted.

Nevertheless by the 1850s patterns were changing. The new methods of transport were tapping the old steamboat market. River trade continued to thrive, often reaching new high totals; at the same time, however, railroads and canals took an ever greater share. The Civil War of 1861–65 played havoc with river transportation; for many miles gunboats replaced steamboats and the railroads proved their growing efficiency.

The postwar period saw a revival of steamboating, with new vessels and new spurts of prosperity. After dark years of neglect, the streams were improved, levees built higher; transportation became safer, and for a time many felt that old times had come back. The year 1870 witnessed a steamboat excitement such as the nation had never known, the greatest race of all.

Almost annually the time upriver had been reduced in successive competitions. The distance from New Orleans to Natchez had taken Henry Shreve five and one-half days; by 1835 it required only a day and 21 hours. In 1853 the "Natchez" (one of many bearing the name) cut the time to 17½ hours. On June 30, 1870, another "Natchez" under Capt. T. P. Leathers, faced the "Robert E. Lee," Capt. John W. Cannon commanding. The two would race up to Natchez and beyond to St. Louis.

Along the river tens of thousands planned to watch; newspapers printed elaborate details and telegraph wires carried information to the world. Men bet unprecedented sums; reputations and fortunes were in the balance. The result was a raging contest and also a bitter controversy. Cannon stripped down his "Lee," rejecting freight, ripping out rigging, upper works, even doors and shutters to cut wind resistance, carrying jute knots and fat side meat to feed the fires. Leathers, more confident for his "Natchez," quietly took on some small freight, otherwise everything would be as usual, he said.

The race began at New Orleans at 5 P.M. A short way upriver at Baton Rouge, La., Cannon made a surprise maneuver; he had arranged to have a fast boat loaded with additional fuel. The "Lee" did not stop to load as expected, but slowed up while the other vessel lay alongside under full steam, and the transfer was thus made. The "Natchez" had to use the usual method. Yet thousands were certain that the latter boat would make up the gap. At Memphis, Vicksburg, Miss., Cairo, Ill., and other points the interest boiled high, but the "Lee" won, reaching St. Louis in 3 days, 18 hours and 14 minutes.

Slowly the old-time steamboats retired from the river. Today

towboats and barges move in a heavy stream along the Mississippi and its tributaries; inland waterways development has brought a new prosperity, but of a different sort. The days of glamorous passenger service, of arrogant "palaces," colourful crews and roustabouts live on only in story and song.

**MISSOULA,** a city of western Montana, U.S., on the Clark fork of the Columbia river, at the mouth of the Bitterroot; the seat of Missoula county and the seat of the state university, opened in 1895. The city lies at the foot of the mountains in a broad valley which is the bed of a glacial lake, at an elevation of 3,223 ft. Missoula valley is the hub of five great western valleys —lower Flathead, Bitterroot, Hellgate, Blackfoot and St. Regis. The city is a regional headquarters for the U.S. forest service and is the training centre for the famous smoke-jumping crews of forest fire fighters. Ft. Missoula, a pioneer fort now inactive, is located near the city. The Flathead Indian reservation is about 30 mi. N.W. The federal laboratory for the study and control of Rocky mountain spotted fever and similar diseases is at Hamilton, 35 mi. S.

The lumber industry is represented by a large mill at Bonner, 10 mi. E., and a paper pulp mill west of the city. A large beet sugar refinery is located in the city. Dairy products are also important.

The first settlement in the region was made in 1841, when Father Pierre Jean de Smet founded St. Mary's mission at the present Stevensville, 30 mi. S. of Missoula. The area now included by Missoula county was successively a part of Oregon, Washington and Idaho territories before Montana territory was formed in 1864. The city was founded in 1865 and incorporated in 1885; the name is from an Indian word of uncertain meaning. Missoula adopted a commission-manager form of government in 1954, but returned to the mayor-council form in 1958. For comparative population figures *see* table in MONTANA: *Population.*

(M. G. Bu.)

**MISSOURI,** popularly known as the "Show Me" state, one of the west north-central states of the United States. Its area is 69,686 sq.mi., including 548 sq.mi. of inland water, making it 19th in size among the states. Its greatest width is 282 mi., length 304 mi. On the east the Mississippi river separates it from Illinois, Kentucky and Tennessee; on the north is Iowa and a short stretch of the Des Moines river; on the south is Arkansas; and on the west are Oklahoma, Kansas and Nebraska, with the Missouri river bend on the northwest. The state takes its name from the Missouri river, called by explorers after a neighbouring Indian tribe; the meaning of the word is not known. Missouri was admitted to the union in 1821 as the 24th state; its capital is at Jefferson City. The state flower is the downy hawthorn (*Crataegus mollis*), the tree the dogwood and the bird the bluebird. The state motto is a quotation from Cicero, *Salus populi suprema lex esto* ("Let the Welfare of the People Be the Supreme Law"); "Missouri Waltz" is the official state song. The state flag, adopted in 1913, has three horizontal bars of red, white and blue, on which is a circular device enclosing the state coat of arms surrounded by 24 stars.

## PHYSICAL GEOGRAPHY

**Physical Features.**—The area that is now Missouri (between 36° and 40° 35' N. lat. and 89° 5' and 95° 45' W. long.) was alternately sea bottom and dry land at many times during its geologic history. Only large bodies of water could have deposited such huge and uniform areas of rock. Ripple marks are common in the sandstone of the Ozarks, and fossils in the rock show remains of coral and other sea organisms. Marine sediments probably covered even the ancient granite and porphyry hills, though later erosion has removed some overlying rock, exposing the igneous strata. At one time molten rocks formed the entire surface of the state; as these cooled, stream erosion created a vast plain interrupted by occasional knobs, mountains and valleys. Into the primeval sea rivers emptied mud and clay which became shale; sand turned into sandstone; gravel became conglomerate; and the remains of sea organisms helped form limestone (calcium carbonate) and dolomite (calcium magnesium carbonate). Factors in the formation of the state's four geologic regions were glaciation, uneven arching of bedrock, and erosion and weathering of various types of rocks.

*Glaciated Plains.*—Two major glaciers covered most of north Missouri; a third glacier entered from Illinois, affecting St. Louis and St. Charles counties. To the west of Jefferson City glaciation crossed the Missouri river to the northern edge of Pettis county; to the east it stopped a few miles short of the present river bed. Glaciers forced streams out of their valleys in the bedrock with deposits of clay, sand, gravel and boulders.

*Ozarks.*—Great springs, caves and sinkholes are common in the Ozarks and bordering areas where ground water has dissolved soluble dolomites or limestone. Springs also flow from beds of permeable material, such as sandstone. The Missouri Geological survey defines this region of hills, plateaus and deep valleys as extending to the north bluffs of the Missouri river valley as far west as Glasgow. The eastern margin spills over into Illinois from St. Charles county, returning to Missouri at Cape Girardeau and running southwest through Poplar Bluff and into Arkansas. The western edge stops short of Sedalia, Osceola and Springfield, which are in the western plains region, thence extends southwest to the tip of Oklahoma. Some streams follow courses cut thousands of years ago through sediments, occasionally encountering hard knobs of granite or porphyry, with a consequent narrowing of the valley to form what are called locally shut-ins. In the course of time the Ozarks were worn down to a plain, on which sluggish streams meandered in crooked channels similar to those of the present Mississippi. When the Ozarks were again uplifted, the streams stayed in their old channels, cutting deep valleys, some as much as 400 ft. below the adjacent uplands. The state's highest point is Taum Sauk mountain in Iron county, 1,772 ft. While large areas of the Ozarks reach 1,400 ft. in altitude, parts are less than 1,000 ft. above sea level; elsewhere in the state elevations above 1,200 ft. are not unusual. (*See* also OZARKS.)

*Western Plains.*—The bedrock of the plains adjacent to the Ozarks is cherty or flinty limestone with lower layers of shale. Large limestone quarries are common around Springfield, Osceola and Sedalia; pure, brittle limestone that takes a marblelike finish is found in the vicinity of Carthage and Joplin. The bedrock is younger west of a line through Jasper, Cedar, St. Clair, Benton, Pettis and Saline counties; in these sediments are deposits of coal, oil and gas.

*Southeastern Lowlands.*—Long after the seas had permanently withdrawn from the rest of Missouri, an arm of the last sea to reach the state extended from the present Gulf of Mexico, covering the lowlands that were in the process of sinking. This sea deposited a thick accumulation of sand, clay and shale, later easily eroded by the Mississippi river. This area includes Stoddard, Dunklin, New Madrid, Mississippi, Pemiscot and parts of Butler, Bollinger, Scott and Cape Girardeau counties; altitude 230 ft.

**Climate.**—The weather in general is changeable, but there are many periods when it is settled and moderate; winters are fairly brisk, with occasional short periods of extreme cold; excessively warm summers are the exception. Average number of days with temperatures below 32° F. ranges from about 105 in the north to about 65 in the extreme southeast. Average annual precipitation ranges from about 50 in. in the southeastern lowlands to 32 in. in the extreme northwest, about 42% falling in the crop-growing months, May through August. Occasionally, summer thundershowers are accompanied by hail and high winds. Tornadoes, usually with narrow paths, dip down once or twice a year, often disintegrating after a few miles. Extremes of heat, cold, drought and moisture occur. Winters in the Ozarks are milder than in the upland plain and prairie section, largely due to differences in latitude, but summers average cooler because of the higher altitude.

**Soil.**—A blanket of wind-blown dust or loess spread over much of the state during the glacial period. This thick yellow silt caps the bluffs on the Missouri and the Mississippi upstream from the central part of the state, in the northwest, to depths of 50 to 75 ft. Bands of alluvium in the bottom lands of the larger streams form

another area of productive soils. Glacial till, clay with a small mixture of sand and gravel, found in the north, varies in fertility, depending on plant organic material. In the Ozarks bedrock is mainly cherty limestone and dolomite, which tends to gravelly or stony soils low in fertility. Shales are the most important soil-forming materials in the prairie region of the southwest. Most upland areas have a heavy or claylike subsoil, favourable to retention of water in ponds but reducing absorption and increasing runoff and erosion. Depth of surface or topsoil ranges from one to three feet for most alluvial or bottom-land soils to four inches or less on severely eroded hillsides. Loess soils in the northwest are 18 in. or more deep. Approximately ten inches is normal throughout the northeastern, central and southwestern sections, and six to eight inches in most of the Ozarks. Deepest soils are in the drainage area of the southeast lowlands and in the Missouri and Mississippi bottoms.

**Vegetation.**—Forests (mostly oak-hickory type) once covered more than two-thirds of Missouri, although the prairie lands of the north and west had trees only in the valleys. Most of this was cut over during the period of ruinous lumbering in the 19th and early 20th centuries (see *Lumbering*, below), and the lush grass of the original prairies has disappeared. Even today, however, black willow, sycamore, red cedar, American elm, oak, hickory, ash, walnut, hazelnut, linden and maple trees may be found throughout the state, as well as honey locust, dogwood, redbud, sumac, hackberry, persimmon, papaw, wild plum, cherry and crab apple. Many kinds of berries grow wild, as do wild flowers; from spring to late autumn, forests and pastures are bright with goldenrod, milkweed, spiderwort, sweet William, roses, bloodroot, columbine, verbena, shooting star, jack-in-the pulpit, trumpet vine, bittersweet, asters and many others. The swamp regions that remain have characteristic vegetation, including bald cypress, corkwood, water locust, swamp cottonwood, etc.

**Animal Life.**—The large game animals—buffalo (bison), elk, black bear, panther, antelope, badger—that once were numerous in Missouri have all disappeared past recall. Others, such as snakebird, deer and beaver, whose numbers were reduced by hunting, lumbering and land cultivation, are being brought back by conservation efforts. A nonpartisan conservation commission, first provided for in 1936 and financed largely from sale of hunting and fishing permits, has co-operated in habitat development, restoring food, cover and water for animal life. Encouragement of farm pond construction, erosion control plantings of shrubs and a program of education have increased the numbers of principal small species—quail, rabbit, squirrel and doves. Live trapping and redistribution multiplied beaver from a few colonies to populations permitting an annual open season on all major streams. Deer were similarly increased to an estimated 250,000 animals, distributed state-wide, with a legal harvest of about 14,000 annually. The commission developed over 30 areas for waterfowl shooting, warm-water fishing, trout fishing, general hunting and natural production of wildlife for trapping and redistribution. Lying in the heart of the great Mississippi flyway, Missouri is visited by more than 400 kinds of birds, and waterfowl-hunting opportunities have been increased by public shooting areas.

**Parks.**—The state park board of the department of conservation maintains cabins, camping grounds and dining lodges in many of the 30 state parks, approximating 70,000 ac. The most popular of these are around the large springs in the Ozarks. Alley Spring State park, in Shannon county, has an old mill and a pool fed by an average flow of 80,800,000 gal. of water a day. Bennett spring, near Lebanon, is larger, and Big spring, the largest single spring in the U.S., near Van Buren, pours 252,000,000 gal. daily into Current river. Similarly picturesque parks are Montauk, in Dent county; Roaring River, in Barry county, and Round Spring, in Shannon county.

Lake of the Ozarks State park, near Osage beach, the largest of the parks, has 89 mi. of shore line and about 4,000 ac. of water. The lake itself, formed by a hydroelectric power dam on the Osage river, is the largest lake in Missouri, with a shore line totaling 1,372 mi. Several streams flowing in deep valleys have been dammed, providing extensive multiple-purpose reservoirs combining facilities for water recreation with flood control, municipal water supply and electric power production: Taneycomo and Bull Shoals lakes (White river); Clearwater reservoir (Black river); Wappapello reservoir (St. Francis river). Preservation of the swift-flowing Current, Jack's Fork and Eleven Point rivers in their natural state has been the objective of conservationists and the national park service.

Tourism is an important business in Missouri. The $500,000,000 spent annually by tourists places it 11th among the states in this regard. Points of interest are the Truman library, at Independence; the Harry S. Truman Birthplace Memorial shrine, at Lamar; the George Washington Carver National memorial, near Diamond; and the boyhood home of Gen. John J. Pershing at Laclede.

## HISTORY

Numerous Indian mounds scattered about the state and discoveries of almost every type of arrowhead and spear point indicate an early and varied prehistoric population. Perhaps the largest mound is one found in Pemiscot county that is 400 ft. long, 250 ft. wide and 35 ft. high, surfaced with a sort of soft brick.

Early French explorers, Louis Jolliet and Jacques Marquette, opened communication from Canada by way of the Great Lakes and the Mississippi river in 1673. Although the Spanish Hernando De Soto discovered the Mississippi in 1541, René Robert Cavelier, Sieur de La Salle, who reached the Gulf of Mexico from upstream in 1682, claimed formal possession of the entire valley for France. Though some early historians credited both De Soto and Francisco Vásquez de Coronado with reaching the Missouri country, it is now considered that both stopped short of this.

In a two-day period, March 9–10, 1804, upper Louisiana, which in 1812 became the territory of Missouri, was successively under three flags, Spanish, French and American. The Louisiana Purchase of 1803 did not end the power struggle over the mid-continent. Spanish policy thereafter was directed toward dismemberment of the United States or at least prevention of southwestward expansion toward Mexico, or New Spain. Large Spanish land grants west of the Mississippi had been given to American settlers in a mistaken effort to encourage disaffection, and some Americans in high places were on the pension list of the Spanish king. During the earlier period of French control fabulous reports of silver deposits near the Meramec river resulted by 1720 in mining operations by the Company of the Indies, a part of John Law's Mississippi bubble (*see* LAW, JOHN), in what became the world's greatest lead field.

Under the same speculative auspices Ft. Orleans was built on the Missouri river in what now is Carroll county. This trading post was designed to cultivate Indian relations as a countermove to a Spanish advance that had met disaster in what now is Nebraska. This farthest west outpost was abandoned by 1728 or 1729. Missouri's first permanent settlement, Ste. Geneviève, dates from about 1735, when French-Canadian habitants of Kaskaskia crossed the Mississippi from the Illinois country to work the lead mines.

Founding of St. Louis (*q.v.*) as a fur-trading post by Pierre Laclède Liguest came in 1764. Nearby, at the mouth of Des Pères river, as early as 1700, French Roman Catholic missionaries had set up a short-lived station with a large Indian population. A trading post that became St. Charles was established 21 mi. N.W. of St. Louis in 1780; this was the first state capital, 1821–26.

**American Migration.**—Encouraged by the Spanish ambassador to the United States, Col. George Morgan of New Jersey in 1789 gathered a party of 70 Americans to found a model city, New Madrid, across from the mouth of the Ohio, where two French-Canadians had a trading post. Failing to receive concessions, including self-government, from the governor general at New Orleans, Morgan returned east, though many of his associates remained. Development of this southeastern area was impeded for years by the severe earthquake of 1811–12, which turned much land into swamp. Upriver, on higher ground, Louis Lorimier prior to 1793 received a grant to what became Cape Girardeau, where a small post had been established several years before.

Most of the newcomers were Americans.

A landmark near Defiance, in St. Charles county, is the house built by Nathan Boone, in which his father, the frontiersman Daniel Boone, died in 1820. The elder Boone having lost his Kentucky land claims welcomed the offer (1795) of Spanish Lieut. Gov. Zenon Trudeau to provide 845 ac. in Femme Osage district, where Daniel Morgan Boone, his eldest son, previously had settled. A party of settlers, including his youngest son, Nathan Boone, came with the famous pioneer, who was given a magistrate's office. That central Missouri district popularly called the Boonslick country was connected with St. Charles by Boonslick road, a main trail for settlers by 1822. At the terminus of Boonslick road was the town of Franklin, long since washed into the Missouri river, an early outfitting point for the Santa Fe trail and boyhood home of the scout Kit Carson. There a government land office had first year sales (1815–19) exceeding 662,000 ac., valued at $1,894,000, less than $3 an acre. By 1830 the Boonslick country had a population of 43,394 out of the state total of 140,455.

Moses Austin in 1797, with a background in lead mining in Connecticut and Virginia, obtained a Spanish grant to Mine à Breton (or Burton), where the town of Potosi developed, in Washington county. Improving on older methods, Austin sank the first mine shaft, built furnaces, a shot tower and sheet lead plant in the woods, as well as a sawmill, flour mill, roads and bridges. Involvement in failure of the Bank of St. Louis in the panic of 1819 led him to attempt to recoup his fortunes in Texas, then a part of New Spain, where he was to settle 300 families. His death in 1821 left his son, Stephen F. Austin, to carry on as the "Father of Texas," one of the long line of Missourians whose further migrations gave the state the name "Mother of the West."

**Indian Relations.**—When the white man came, the Osage and the Missouri were the main Indian tribes, apparently numbering about 15,000. Sauk and Fox war parties had almost destroyed the Missouri by 1789. Early exploration of the upper reaches of the Missouri by Meriwether Lewis and William Clark (1804–06) and two expeditions by Zebulon M. Pike, sent by Gov. James Wilkinson to the north and the southwest, encouraged trade relations, as well as added to geographic knowledge. During the War of 1812 Indian unrest stirred by the British and the Tories who had fled to Canada menaced outlying settlements. The governorship of Clark (1813–20) and his later administration of Indian affairs developed confidence among the chiefs, who often visited him in St. Louis, the administrative centre. Friction with remaining tribes was lessened by giving them lands farther to the west before settlers swarmed in.

In a final treaty with the Big and Little Osage nations in 1825, Clark awarded them a 50-mi. square tract in Kansas; a $7,000 annuity for 20 years, in money, merchandise, provisions or domestic animals, as desired; 600 head of cattle, 600 hogs, 1,000 domestic fowls, 10 yoke of oxen and 6 carts, farming implements and a blacksmith paid by the government to keep the tools fit; and comfortable and commodious houses for the principal chiefs. The proceeds of 54 sections of land were to support an Osage school, and reservations were to be established for mixed Indians-whites.

**Building a State.**—Desire for self-government was realized on Aug. 10, 1821, when Missouri was admitted to the union as the 24th state. (The struggle that took place in congress before the state's admission is described in the article MISSOURI COMPROMISE.) The population was 70,000. Southerners, comprising the first wave of settlers after statehood, took over fertile bottom lands as farmers, unlike their French predecessors, who had gathered in communities and tilled only small common fields, living mainly on the fur trade. No taxes had been collected by France or Spain; by 1805 U.S. authorities announced that taxes could be paid in shaven deerskins at the rate of three pounds to the dollar before a certain date. A shortage of currency made lead, as well as pelts, a medium of exchange.

Opening of steamboat transportation on the Mississippi in 1817 (two years later on the Missouri) quickened and expanded the fur trade. Trappers worked more than 1,000 mi. up the Missouri, also reaching the Green river, and perhaps Great Salt lake, and opening South pass to California and Oregon. It was estimated that 250,000 buffalo were killed in 1848, and 25,000 buffalo tongues were shipped to St. Louis. The western branch of John Jacob Astor's American Fur company brought back 67,000 buffalo robes in 1840. Cargoes of tallow from bear and buffalo, a substitute for lard, sometimes were poured into hollowed-out boats and towed to market. Finally the development of the silk hat and an accompanying fashion for other furs diminished the market, much of which had been for manufacture of felt or beaver hats.

In much the same way the day of the steamboat passed. The first steamboat reached St. Louis in 1817, and the traffic expanded rapidly. In 1860 more than 5,000 vessels arrived at St. Louis. But the American Civil War played havoc with river traffic, and after the war the frantic interest in railroading also led to the decline of the steamboat. (*See* also MISSISSIPPI RIVER STEAMBOAT.)

Bonds issued to promote rail lines during the period of intensive speculation cost the state treasury $25,000,000; many towns and counties bonded themselves for lines never built. The first railroad across the state, the Hannibal & St. Joseph (1859), short-cut Missouri river traffic and was connected with St. Louis by the North Missouri line at Macon. Four years earlier the Pacific railroad had been extended from St. Louis to the capital, Jefferson City; by 1865 this reached Kansas City on the western border. By 1858 the St. Louis & Iron Mountain railroad had an 86-mi. line to the Pilot Knob mining district; another line had reached Rolla by 1861. The great Eads bridge across the Mississippi at St. Louis was completed in 1874, a lower deck for rail traffic competing with the ferries; since 1857 a railroad from Cincinnati had disembarked passengers on the east bank of the river.

In the meantime overland trade with Santa Fe, N.M., had boomed from its opening in 1821, when Mexico had freed itself from Spain. The first expedition, by William Becknell and 21 men, started from Franklin. By 1827 the take-off had shifted west to Independence, and in the '40s to Westport, later a part of Kansas City. Traffic in cotton goods, cutlery and easily freighted products reached a value of $250,000 by 1831. A good part of this was in Mexican silver dollars, which were cut into halves, quarters and half-quarters, or bits, as preferable to wildcat paper. The exchange also laid the foundation of Missouri's extensive mule trade; in 1832 the caravans brought back 1,300 mules, jacks and jennets, or female burros. (*See* also SANTA FE TRAIL.)

**Slavery and Politics.**—Well-to-do southerners moving west for cheap land chose Missouri in preference to the Northwest territory, where slavery was forbidden. Slave labour also had been used extensively in French lead mining. At the outbreak of the American Civil War there were 144,000 slaves and 29,000 masters in a total Missouri population of 1,182,000; these Negroes were taxed as property, assessed at $44,000,000 in 1860. The traditional southern institution came under question by later arrivals from the north and by the German immigrants who began to arrive in the 1830s. To a certain extent free labour was discouraged by slave competition, but the growing abolition movement was based on moral rather than economic grounds, while defense of slavery was involved in the emotional issue of states' rights.

The controversy mounted after statehood was granted under the Missouri Compromise (*q.v.*). Sen. Thomas Hart Benton as early as 1828 sought backing for gradual emancipation allied with an educational program. Elijah P. Lovejoy in 1837 was forced to leave St. Louis by a mob that pillaged the print shop from which his abolitionist *The Observer* was issued; five weeks later he was killed across the river, in Alton, Ill. The difficulties experienced by the Mormons in Independence and later in Daviess and Caldwell counties (1831–39) were based partly on the fact that the Mormons, mostly northerners and easterners, were abolitionists while their neighbours, many from southern states, were not. (*See* also LATTER-DAY SAINTS, CHURCH OF JESUS CHRIST OF.) The legislature in 1847 established penalties for teaching any Negro to read or write and forbade any free Negro to enter the state. Benton's refusal to push the slavery cause ended his 30 years in the senate in 1851.

The Dred Scott case, originating in St. Louis in 1846 and calling into question the constitutionality of the Missouri Compromise limitation on slavery, sharpened the issues. Annexation of Texas,

*Top right:* The state capital, Jefferson City. In the right foreground is the governor's mansion.

*Centre left:* Blockhouse of Fort Osage, Sibley, established in 1808 as a military and trading post by William Clark of the Lewis and Clark expedition.

*Bottom left:* Picking cotton near Kennett, business centre of Dunklin county. Cotton is a major agricultural product of the state.

*Bottom right:* Marble quarry, Carthage, an area rich in marble, zinc and lead.

war with Mexico and the Kansas-Nebraska act of 1854 found Missouri officially on the slavery side. The Kansas-Nebraska act, leaving the question of free soil or slavery to residents of the territories, led to persistent border troubles between Missouri and Kansas (*q.v.*), in which peaceful citizens suffered. Emancipation was advocated by the Free-Soil movement in 1856, led by Francis P. Blair, Jr., and B. Gratz Brown. In the first summer of the war Gen. John C. Frémont from headquarters in St. Louis proclaimed the freedom of all slaves owned by active secessionists in the state. This was reversed by President Lincoln's policy, which sought to compensate border-state slaveowners in advance of unpaid emancipation in the Confederate states. Nothing coming of this, the state legislature in 1863 voted for gradual emancipation and abolition by 1870. The new state constitution, proclaimed by Gov. Thomas C. Fletcher, a radical Republican, on Jan. 11, 1865, abolished slavery.

**Civil War and Reconstruction.**—Of all Missourians of military age 60% served in the war, 109,000 in the Union army and 30,000 in the Confederate. Federal casualties reached 14,600 dead. While many engagements were fought in the state, that of greatest magnitude was the battle of Wilson's Creek, Aug. 10, 1861, in which Gen. Nathaniel Lyon was killed and his outnumbered Federal troops forced back toward Springfield. Governor Jackson, who advocated secession, had fled from Jefferson City before Lyon's advance, and a provisional government, headed by Judge Hamilton R. Gamble as governor, was established through action by a delegate convention that had voted against secession. Efforts to take St. Louis, stronghold of Union strategy, were defeated by Gen. U. S. Grant at Belmont, Mississippi county, and by Gen. Thomas Ewing at the battle of Pilot Knob in Sept. 1864. In the latter attack Gen. Sterling Price lost 1,000 men out of the Confederate force of 12,000; Union losses were 200. Ruins of the earthworks of Ft. Davidson, the Federal stand, are visible along the Iron county highway. Swerving back across the state, Price finally was defeated in the battle of Westport, three days' losses amounting to 1,000 on each side, putting an end to Confederate hopes in Missouri.

Guerrilla warfare ravaged Missouri throughout the war, particularly along the Kansas border. Gen. Thomas Ewing, of the 11th Kansas volunteers, by his drastic order no. 11 in 1863 compelled all residents of several Missouri border counties except those within a mile of principal towns to leave their homes within 15 days. Those proving loyalty could stay at any military station or move to the interior of Kansas. All grain and hay not delivered to the nearest post was destroyed. A famous painting by the Missouri artist George Caleb Bingham depicts a family leaving their looted and burning home, a picture indicating the reaction to the deportations even by Union sympathizers.

Similar revulsion arose at the end of the war to a new state constitution listing 86 acts that a citizen must deny under oath in order to vote. No person who had aided or sympathized with the Confederacy could function as a lawyer, teacher or minister. The constitutional convention also ordered all court officers removed in order to forestall legal obstruction. The radical Republicans could not realize that the war was over, and it was 1870 before Sen. Carl Schurz, supported by conservative Republicans among his fellow Germans and with the aid of the reorganized Democratic party, elected B. Gratz Brown governor and obtained repeal of the loyalty test (its clause disqualifying professional men from practice had previously, in 1867, been declared unconstitutional by the U.S. supreme court). In 1872 Democrats assumed control of the state and in the ensuing 88 years were interrupted by only five Republican governors. The period closed with a new constitution drawn up in 1875, putting a limit on taxes, requiring a two-thirds majority in bond elections and limiting state debt to $250,000 in any one year, a reference to heavy losses in railroad financing.

Major historical developments in the 20th century have included the framing and adoption in 1945 of a new state constitution, including the nonpartisan plan for electing judges that came to be known as the "Missouri plan" and was followed by several other states; the general trend toward increasing urban population and declining rural population; the successful integration of public and parochial schools; the development of public health and welfare programs; and economic developments marked by increasing farm mechanization and expanding industrial and mineral production, all discussed in more detail below.

Mid-20th-century sessions of the general assembly authorized watershed conservation districts; tightened regulation of nursing homes for the aged (after loss of 72 lives in a fire); and widened the powers of the Bi-State Development agency to own and operate facilities, from bridges to airports and transportation, in the metropolitan area adjacent to St. Louis in Missouri and Illinois.

## GOVERNMENT

Under the constitution adopted in 1945 six executive officers are elected for four-year terms: governor, lieutenant governor, secretary of state, state auditor, state treasurer and attorney general. Election of the auditor is held independently, at mid-term. All other heads of departments are appointed by the governor. There are 114 counties, plus the city of St. Louis, which ranks as a county in itself. Each county is entitled to at least one member in the house of representatives, the more populous counties having more, all elected for two-year terms. There are 34 senatorial districts, each elects one senator for four years, half of the body coming up for election every two years. The general assembly meets in the capital, Jefferson City, in odd-numbered years.

Under a nonpartisan court plan the governor appoints one of three persons named by a special commission to fill vacancies in the supreme court and courts of appeals. The chairman of this nonpartisan commission is the chief justice of the state supreme court; members of the bar in each appeals district elect one member, and the governor selects one citizen, not a member of the bar, from each of the three appeals districts. At the next general election after the appointee has been on the bench for at least one year the people vote on a special ballot as to whether he shall be retained in office. Vacancies in circuit courts of the city of St. Louis and in Jackson county (Kansas City) are filled similarly. Upon expiration of a judicial term an incumbent wishing to succeed himself is listed on a ballot without party designation, and voters vote yes or no on the question as to whether he shall be retained in office.

Sales tax receipts provide about 61% of the state's general revenue, income tax 23%, liquor taxes 4.44% and general property tax 1.25%. A gasoline tax is earmarked for highway use.

## POPULATION

The 1960 census recorded a population of 4,319,813, an increase of 9.2% over the 1950 population of 3,954,653. Population in 1810 was 19,783; in 1860, 1,182,012; and in 1900, 3,106,665. Allowing for area adjustments in 1963, the state's four standard metropolitan statistical areas—Kansas City (shared with Kansas), St. Joseph, St. Louis (shared with Illinois) and Springfield—had a 1960 total population of 3,414,071 (including 457,198 in Illinois and 329,287 in Kansas). Only 33.4% of those enumerated constituted the rural population.

In 1960 nonwhites in the state were 9.2%, almost all Negro. Foreign-born white were 1.8%, mainly from Germany. Italy and the United Kingdom ranked next, and there were considerable numbers of Irish, Austrians and Poles.

The population per square mile in 1960 was 67.0, as compared with 57.1 in 1950 and with 49.6 for the U.S. in 1960. The number of occupied dwelling units (or households) in 1960 was approximately 1,360,000, as compared with 1,190,000 in 1950. The average household size had declined from 3.3 in 1950 to 3.2 in 1960.

There were 97.2 males per 100 females in the 1960 population, as compared with 96.4 in 1950. Of the population 14 years old and over, 53.7% was in the labour force. 13.0% of employed males were engaged in agriculture, 7.8% in construction, 26.4% in manufacturing, 5.8% in transportation, 17.6% in wholesale and retail trade and 11.2% in service activities of all kinds.

The most conspicuous population trend is that toward increase in urban and comparative decline in rural population, but the latter is real as well as comparative. In 1960, with 786 places of less

*Populations are reported as constituted at date of each census. †Returned until 1918 as Florissant, from 1920 to 1940 as St. Ferdinand and from 1940 as Florissant.
Note: Dash indicates place did not exist during reported census, or data not available.

than 2,500 population, offering little employment opportunity, a heavy migration, particularly of younger people, to industrial centres, some outside the state, was under way. Most counties have experienced a population decline, and many of them had fewer people in 1960 than they did in 1890; in the northwestern half of the state all counties without major cities had fewer people than they had in 1890. The six southeastern counties are the only rural counties to show upward trends. The percentage of persons 65 years of age and older was 2.2% higher than the national average, explainable largely by the emigration of younger persons.

## EDUCATION

Efforts to obtain a standard level of educational opportunity in both urban and rural schools led to the establishment of a foundation program of equalization in 1955. It was successful in reducing the number of school districts, which numbered 8,400 in 1947, to fewer than 3,000 by the late 1950s. In addition to consolidation, the foundation program offered incentives and means for improved teaching. The state constitution requires that at least one-fourth of general revenue be apportioned for support of public schools; to this a cigarette tax was added under the foundation program. Legal limitations prevent use of state school funds for children under 6 years of age and for persons 21 or over, and this interferes with kindergarten and adult educational activities. A state board of education composed of lay members appointed by the governor performs routine functions, with an administrator in charge.

Special schools include the State School for the Deaf, at Fulton, and the State School for the Blind, at St. Louis.

**University of Missouri.**—The University of Missouri, first state university west of the Mississippi, was established in 1839. It later became the first land-grant college in the west through its school of agriculture and mechanical arts on the main campus at Columbia and the school of mines and metallurgy at Rolla. In the early 1960s there were 14 schools and colleges on the 900-ac. main campus, with an enrollment of more than 11,000 full-time resident students, and 3,000 additional students at Rolla, a centre of scientific research and engineering. More than 10,000 correspondence students were enrolled annually, and 1,160 were in extension courses for college credit. The agricultural extension service reached thousands of persons for farm and home programs, and the agricultural experiment station conducted research, teaching and field work on more than 23,000 ac. of farm lands and timberlands, as well as in laboratories.

The school of journalism, established in 1908, was the first of its kind; it operates a newspaper and provides a staff for the radio and television stations. The college of arts and science includes the school of social work. The schools of forestry and of home economics are allied with the college of agriculture. There are also colleges of education and of engineering; a graduate school; a school of business and public administration; a school of law; a school of medicine, including a school of nursing and a separate school of veterinary medicine.

The university library contains nearly 1,000,000 volumes.

**Other Institutions of Higher Education.**—Broadening of the curriculum of state normal schools led to renaming these, each under its regional board of regents: Northeast Missouri State Teachers college (founded 1867), Kirksville; Southeast Missouri State college (1873), Cape Girardeau; Central Missouri State college (1870), Warrensburg; Northwest Missouri State college (1905), Maryville; and Southwest Missouri State college (1906), Springfield. Lincoln university, established for Negroes in 1866 at Jefferson City, has been integrated racially, as have other state schools. In 1808 Ste. Genevieve academy was chartered, and such private or church-related schools reached 204 by 1850. Ten denominational colleges, chiefly Protestant, belonged to the Missouri College union in the early 1960s. These were included among 19 senior colleges, of which St. Louis university (Roman Catholic; 1818) and Washington university (nonsectarian; 1853), both of St. Louis, were the largest (*see* ST. LOUIS). The University of Kansas City (nonsectarian), chartered in 1929, enrolls nearly 2,000 students annually and has a library of approximately 200,000 volumes. There were also 14 junior colleges, including several operated as part of the public-school system of some communities, and a number of religious seminaries.

## HEALTH AND WELFARE

Missouri has pioneered in the mothers' pension plan (aid to dependent children originated in Jackson county in 1911); in special education for handicapped children; and in harmonizing its juvenile court code with modern conditions. It also integrated its schools in prompt and orderly fashion after the supreme court decision of 1954 declared racial segregation in public schools to be unconstitutional. Such progress seldom has come suddenly by passing laws—Roman Catholic parochial schools ended segregation before the public-school system did—reform originating, in-

stead, in the responsible concern of large groups of citizens. Among such factors are the Missouri Association for Social Welfare, the League of Women Voters, and religious agencies such as the Metropolitan Church Federation of St. Louis, with its counseling service, training programs and interpretation of current needs through radio, television, press and pulpit.

Although hospital facilities have been poorly distributed about the state, St. Louis and Kansas City provide outstanding medical centres. The department of health and welfare, set up under the state constitution of 1945, operates a cancer hospital at Columbia and a tuberculosis sanatorium at Mount Vernon. Its division of mental diseases has hospitals at Fulton, St. Joseph, Nevada, Farmington and St. Louis, in addition to the Missouri State school at Marshall for the care and training of mentally retarded and epileptic children, and the St. Louis Training school for mental defectives between 5 and 20 years of age. The division of welfare assists persons over 65, dependent children, victims of calamity, the disabled and the blind and also administers direct relief and child welfare service. The state department of correction controls a penitentiary for men at Jefferson City and an auxiliary for women at Tipton and the Intermediate Reformatory for Young Men at Algoa Farms, near the capital. There are also several prison farms, with two canneries, two dairies, a pickle factory, a slaughterhouse and two quarries. In 1957 the site for the medium security prison was acquired near Moberly. A training school for boys is at Boonville, that for girls at Chillicothe.

## ECONOMY

Nearly half the counties by the 1960s had no village with a population as large as 2,500, and only 18 counties had towns larger than 10,000. Increasing farm mechanization had resulted in two-thirds of rural youth, mainly those of greater aptitude, both men and women, leaving to seek economic opportunity in larger centres. The result was a reservoir of unskilled labour at wages slightly below the national level. Four distinct rural areas stem from interacting economic, social, cultural and physical characteristics. Largest is that north of the Missouri river, extending south along the western border to Jasper and Lawrence counties; this has a relatively high level of living, with emphasis on education and commercialized farming. Another begins with Cole county, extending along the Missouri and Mississippi to Cape Girardeau, including early French settlements but with a German background, dating to 1837, at Hermann. Here are Lutheran and Catholic parochial schools, less attendance at high school, lower relief expenditures and some off-farm employment. A third division is the Ozarks, populated by descendants of southern highlanders, with much subsistence and part-time farming and a higher birth rate, altogether reminiscent of early America. Six counties in southeast Missouri form the fourth area, with a high percentage of Negro labour, tenant farming, with little permanent tenure, and fixed social classes.

**Agriculture.**—Fewer but larger farms have resulted from increasing mechanization. The bureau of the census in the second half of the 20th century reported a total of about 200,000 farms in Missouri, a decline of 17.5% during and after World War II. The census of 1930 listed 55,000 more farms and an average acre value of $53.23, as compared with $81.45 in the 1950s. Though total acreage in use remained approximately unchanged, average farm size increased in 25 years from 132.2 ac. to 169.6 (28%). Missouri ranks third in farm co-operative membership, following Minnesota and Illinois. The Missouri Farmers association, centred in Columbia, marketing crops and processing and distributing supplies ranging from seeds to tractor fuel, reported over 155,000 members in the second half of the 20th century, operating three feed mills, three fertilizer plants, two plants processing poultry, eight handling milk, and a packing house. The Consumers Co-operative association of Kansas City, a regional supply agency operating in 11 states, reported $130,000,000 of supplies distributed annually, mainly petroleum, fertilizer and feed. Loans from the Rural Electrification administration, chiefly to co-operatives, by the early 1960s had provided power to nearly all the state's farms. The number of tenants decreased from a peak of 91,000 in 1940 to 35,000 in a period of 15 years. Factors favourable to better rural living included the soil conservation service (through erosion control and water management) and the Farmers Home administration, both in the U.S. department of agriculture; the latter provided loans to family-sized operators to improve living and operating conditions and for purchase, enlargement or development of farms.

Cash farm income from cattle, hogs, milk, poultry and eggs represents well over 60% of total farm income. Chief crops, in order of cash value, are corn, wheat, soybeans, cotton (flat, an excellent long-staple variety) and hay.

**Industry.**—Of states west of the Mississippi, Missouri ranks third in manufacturing, after California and Texas. A tendency toward decentralization, notably in the shoe and clothing industries, has supplemented the basic food processing and lumber operations usually seen outside metropolitan areas. Wide diversity is reflected in the more than 6,000 industrial establishments, with nearly 400,000 employees, an annual payroll of $1,600,000,000, and a $3,200,000,000 value added by manufacture annually in the second half of the 20th century, the latter sum having nearly doubled in the ten-year period following World War II. The leading industries, in order according to value added by manufacture, are transportation equipment, food and kindred products, chemicals and kindred products, machinery (excluding electrical), fabricated metal products and leather and leather products. Of the 448 classifications used by the federal census of manufactures, nearly 400 are represented in Missouri. The rapidly growing tourist industry, especially after World War II, contributed substantially to the state's economy (see *Physical Geography: Parks* above).

**Mining.**—Mineral production by the early 1960s was valued at about $150,000,000 annually. Missouri leads the states in production of lead, as it has since 1906, and barite; it is the second largest producer of lime and the third of fire clay. Its five principal minerals, in order of value, are cement, stone, lead, lime and coal. Nonmetals account for 63% of the total mineral value, metals 29% and mineral fuels 8%. A notable increase in iron ore potential accompanied drilling discoveries in the Pea ridge district near Sullivan of high-grade deposits estimated at 100,000,000 tons, located at great depths. Government aid in financing exploration for strategic minerals led to discoveries of lead in the Vibernum area of southeast Missouri, said to exceed the old lead belt, which it parallels at a lower level. Bituminous coal is produced in numerous small mines scattered over the state, the largest being found in Henry, Macon, Bates, Barton and St. Clair counties; 96% of the tonnage is supplied by strip mines. Metals in small production include cobalt, copper, nickel, manganese and silver, with less amounts of cadmium, gallium, germanium and indium.

**Forestry.**—Through a system of reforestation, fire protection and tax concessions to owners of well-managed forest croplands, much of the damage of earlier unrestricted lumbering has been offset. While most of the stands were immature in the early 1960s, trees grew on more than 15,000,000 ac., more than one-third of the state. In addition to state forests, comprising 170,000 ac., the Clark and Mark Twain National forests, in the southern Ozarks, protected 1,359,000 ac.

Damage created by open-range livestock in several counties was an obstacle to pulp mill establishment, although protected areas showed possibilities of increased growth. Replanting of 50,000 ac. mainly in shortleaf pine added a new wood to the commoner oak and hickory.

**Trade and Finance.**—Missouri is the only state with two federal reserve banks, one in St. Louis and another in Kansas City, reflecting the central geographic location, with large terminal farm markets and processing and distribution facilities. St. Louis also is a centre of farm credit agencies set up by the federal government but passing into farmer ownership—a land bank, a production credit association and a bank for co-operatives. Many communities have established industrial development corporations to attract new industries.

**Transportation and Communication.**—From the founding

of the first newspaper, the *Missouri Gazette*, by Joseph Charless in 1808, at St. Louis, journalism has developed an aggressive tradition carried on by many noted editors. In the second half of the 20th century the press was supplemented by about 20 television stations and 100 radio broadcasting establishments. The two largest cities were main airline terminals, others being served by regional feeder lines. There were 23 trunk-line railroads, and federal and state highways crisscrossed the state, leaving no point more than a few miles from a modern highway. Many pipelines carrying natural gas, oil and gasoline crossed the state from the southwest. Waterways to the Gulf of Mexico from Kansas City and above had been supplemented by access to the St. Lawrence seaway through the Illinois river canal. Modern towboats made the round trip from St. Louis to New Orleans in 16 days, comparing favourably with schedules of river packets of old days. Whereas a modern tow consisted of 8,000 to 10,000 tons of freight, packets had been hard pressed to handle 600 tons, though some had carried 2,000.

**MISSOURI COMPROMISE,** a term referring to the compromise measures worked out in the U.S. congress that prepared the way for admission of Missouri as the 24th state. The immediate issue was whether slavery should be permanently legalized in the new state; a second issue was the policy of congress toward slavery in the territories west of the Mississippi river.

In Dec. 1818 congress received a petition to authorize Missouri to form a state government. When this was considered in the house of representatives on Feb. 13, 1819, James Tallmadge of New York introduced an amendment providing that no additional slaves should be admitted into Missouri and that children of slaves already there should be freed at the age of 25. Debates on this amendment revived the sectional controversies between north and south which had appeared periodically in the preceding 40 years. The amendment was accepted by the house, but rejected by the senate. Congress adjourned March 4, 1819, without acting on the Missouri bill.

The following summer a considerable body of public opinion in the north was rallied in support of the Tallmadge proposal. Much of this anti-Missouri sentiment, as it was called, arose from a genuine conviction that slavery was morally wrong. Political expediency was mixed with moral convictions. Many of the leading anti-Missouri men had been active in the Federalist party which seemed to be in the process of disintegration; it was charged that they were seeking an issue on which to rebuild their party. The Federalist leadership of the anti-Missouri group caused some northern Democrats to reconsider their support of the Tallmadge amendment and to favour a compromise that would thwart efforts to revive the Federalist party.

The 16th congress assembled in Dec. 1819 and on Jan. 3, 1820, the house voted to enable Maine to form a state government. The senate amended the bill to authorize both Maine and Missouri to frame state constitutions, the latter without restriction as to slavery. To this the senate added an amendment offered by J. B. Thomas of Illinois to exclude slavery from all other parts of the Louisiana Purchase north of the latitude 36° 30′, the southern boundary of Missouri. When the house refused to accept this compromise, Henry Clay took active leadership of the compromise group. Even with all his skill, the compromise proposals probably could not have passed the house as a single bill. A large majority of northern congressmen still were opposed to the unrestricted admission of Missouri while a larger proportion of southern congressmen opposed any limitation on the extension of slavery. Clay forced separate votes, however, and all the controversial measures passed by slender majorities and were signed by President James Monroe on March 3 and 6, 1820.

Final admission of Missouri faced one more hurdle. The constitution of the new state included a provision excluding free Negroes and mulattoes, and a majority in the house was unwilling to vote for the admission of Missouri until that clause was stricken from the constitution. Again Clay worked for compromise and won over enough votes by a proposal to make the admission of Missouri contingent on an act by its legislature agreeing never to impair the rights of the citizens of any state. This is sometimes known as the second Missouri Compromise.

Debates on the admission of Missouri raised constitutional as well as political questions. In the final action congress accepted the southern contention that it could impose no restrictions on new states which did not apply equally to all states. It also accepted the argument of northerners that it did have the power to regulate slavery in the territories. More significant however was the impact upon attitudes toward slavery and sectional interests. The debate alerted extreme antislavery groups in the north to the implications of the extension of slavery, but northern Democrats preferred continued co-operation with southern Democrats to the espousal of a strictly sectional issue. In the south the attack on slavery solidified sectional determination to defend slavery. No southern leader thereafter could support any restriction on slavery and remain in public life; within a few years southern spokesmen were defending the thesis that slavery was essential to the welfare of the south and was indeed morally defensible. In 1854 the Missouri Compromise was repealed.

**MISSOURI RIVER,** longest of the tributaries of the Mississippi, is formed by the confluence of the Jefferson, Madison and Gallatin rivers in the Rocky mountain area of southwestern Montana, 8,000 ft. above sea level. Flowing at first northward onto the high plains, the Missouri then turns eastward before assuming its winding, unstable course southeasterly to the Mississippi. For most of the way the river flows through its two major physiographic sections, the high and the low Great Plains, finally debouching into the Mississippi over its own alluvial plain 2,466 mi. from its source.

**Basin.**—The area drained by this great river system is about 529,400 sq mi., of which 2,550 sq mi. are in Canada. Elevations within the basin are extreme: from 14,000 ft. above sea level in the Rockies near the continental divide to 400 ft. where the Missouri joins the Mississippi.

In general the northern plains are lower than the southern Great Plains. Four areas stand out in contrast with the prevailing surface of the Great Plains. In north central Nebraska are the Sand hills, a region of low sand hills, small enclosed basins and intermittent streams, principally affording pasture for cattle. A second area of rolling terrain with thin limestone soils fitted only for grazing is the Flint hills in east central Kansas. The third hill area is the concentration of erosional land forms in west central South Dakota known as the Bad Lands, where, even under the most favourable climatic conditions, grazing is generally the highest use of the land. The most verdant of the hill or mountain areas on the plains is the Black hills of western South Dakota. Most of this area is national forest, and recreation is the

BY COURTESY OF THE U.S. ARMY CORPS OF ENGINEERS

CONFLUENCE OF THE MADISON, JEFFERSON AND GALLATIN RIVERS NEAR THREE FORKS, MONT., FORMING THE MISSOURI RIVER

source of most of its income. A final hill area is the Ozark highland in the far southeastern part of the Missouri basin. Although well-watered and once forested, the steep slopes and thin soils preclude crop agriculture except in the valley bottoms. Recreation is the major source of income over most of the highlands.

The apparent uniformity of the remainder of the Missouri basin is deceptive. The badland type of topography is found on a smaller scale in many places, particularly in the middle valley of the Little Missouri and along the upper courses of most of the longer rivers. Continental glaciation has also resulted in differentiating the land surface in the northern and northeastern portions of the basin where old glacial channels that once were the beds of glacial lakes, plains, morainic deposits and till plains are found. (*See* also PLEISTOCENE EPOCH.) In east central Nebraska are rolling plains of wind deposition; this loess soil is productive when watered. Most extensive of all subdivisions of the basin are the high plains on the west formed by outwash from the cordilleran glaciation of the Rockies. In the main, soils are fairly deep and fertile. Their ability to absorb and hold water varies widely and is, perhaps, their most critical quality from the viewpoint of agriculture.

The climates prevailing over the basin are arid, with the extreme temperature ranges characteristic of a mid-latitude, continental interior. Most of the larger cities are in the drier western portion, including Denver, Colo., Laramie and Cheyenne, Wyo., and Great Falls and Helena, Mont. Tornadoes, blizzards, torrential rains, heavy snows, sustained high temperatures (perhaps three weeks) and searing droughts have discouraged permanent settlement. In no other part of the interior U.S. are average wind velocities so high as on the Great Plains. The high rate of air movement increases evaporation and promotes dust blowing on fields that are or have been cultivated. Hail insurance is commonly taken on about half of the wheat acreage on a representative farm or ranch on the western Great Plains.

The population of the Missouri basin is about 7,000,000; these states have shown a decline in population since 1930 whereas the nation has significantly increased.

**Flow.**—The flow of the Missouri and of most of its tributaries is exceedingly varied, with the lowest on the Missouri in winter and the greatest from April to June, the flood season. The average flow near the mouth is 64,000 cu ft. per second; the minimum is 4,200 cu.ft., and the maximum is 900,000 cu ft. With unprotected slopes and with such violent fluctuations in flow, erosion and silting are major problems.

**Tributaries.**—The tributaries of the Missouri are nearly all from the west; chief among them are the Yellowstone, Platte, Milk, Kansas, James, Little Missouri, Big Sioux, Niobrara, Osage and Grand, all but the last are essentially Great Plains rivers. Unlike the tributaries of the Ohio, those of the Missouri rarely afford natural corridors through hill or mountain terrain.

**Navigation.**—The mouth of the Missouri was discovered in 1673 by Jacques Marquette and Louis Jolliet while they were coming down the Mississippi. Early in the 18th century French fur traders began to ascend the river, and in 1764 St. Louis was established as a depot; but the first exploration of the river from its mouth to its headwaters was made in 1804–05 by Meriwether Lewis and William Clark. Until many years later the commerce on the river was restricted to the fur trade, and was carried on with such primitive craft as the canoe, the pirogue, the bullboat and the keelboat. The river was little used during the early movement to the west; instead the central route over South pass in west central Wyoming, an important link in the Oregon trail, was followed until railroads were constructed farther south. The first attempt to navigate the Missouri with steamboats was made in 1819. The American Fur company began to use steamers in 1830 and flat-bottomed Mackinaw boats, keelboats and small steamboats were in use on the Missouri below Fort Benton, Mont., 2,285 mi. from the Mississippi, between 1840 and 1870. Steamboat traffic was at its height in 1855, when no fewer than 60 regular packets were engaged in it, but its decline began in the following year with the completion of the Hannibal and St. Joseph railway to St. Joseph, Mo., and by the end of the 19th century it had almost disappeared.

For the first 150 years after settlement along the river little was done to render the Missouri more useful as a waterway or as a source of water for agriculture or power. In 1944 congress authorized a comprehensive program for flood control and water resource development in the Missouri river basin. It embraced a system of more than 100 dams and reservoirs on the Missouri and certain of its tributaries. Local flood protection, involving levees and bank stabilization, and a deeper channel were provided for from Sioux City, Ia., to the Mississippi, a distance of 760 mi. By the time a more ambitious plan, the Missouri River Basin program, or simply the Pick-Sloan program, was presented early in the 1950's, a substantial part of the channel and regulatory reservoir undertaking had been completed or nearly so. Commercial barge lines began operations on the Missouri in 1953 and within a few years their tonnage amounted to more than 400,000 a year—about twice the total at the peak of the old steamboat days.

**Irrigation.**—Irrigation does not stand as a remedy for the drought problem in Great Plains agriculture. In the eastern part of the basin many farmers are by no means certain that its cost is justified in the long run. Rainfall fluctuates so widely around a critical point for crop production that even a slight reduction in moisture affects crop yields seriously. In the larger, drier western portion, it is a physical rather than an economic problem generally. Nearly all of the functioning irrigation districts are on the upper reaches of rivers along the Rocky mountain front. Largest of these districts is the Colorado piedmont from Denver to Fort Collins. Others are in the Big Horn basin of Wyoming, along the larger rivers in Montana, on the North Platte near Scotts Bluff, and on the South Platte from Ogallala to Grand Island, Nebraska. These districts account for the greater part of the 5,000,000 ac. under irrigation in the Missouri basin. The 30 units of the Missouri River Basin program involve 2,500,000 ac. of newly irrigated land and 250,000 ac. with a supplementary water supply. Most of these irrigated districts are on the eastern or low Great Plains, many of them on the shorter rivers which follow generally parallel courses to the Mississippi. On these streams the pattern of irrigated districts is similar to beads on a string. Three large areas of concentrated irrigation development are in eastern Nebraska and the Dakotas. In any such program for conservation in the harsh but relatively simple environment of the western Missouri basin, land use is subject to most of the physical and economic hazards of the humid east, plus others more or less restricted to the higher, drier lands of the west. Hay and sugar beets are most prevalent in irrigated areas. There are other crops important in several districts, including potatoes, fruits and vege-

tables. Prime requisite in these cash crops grown under irrigation is a high return per acre. Beets are grown in rotation with small grains, alfalfa, and sometimes corn, depending upon the elevation; they rarely are the major crop in any of the districts.

Livestock-feeding operations are integrated into the farm program, with beef cattle and lambs being fattened, in part on the feed crops, sugar beet tops and beet pulp.

**Power.**—In addition to irrigation, power development and flood protection are goals of the larger projects. There is no single, integrated power system to serve the entire basin, as in the TVA. At the beginning of the second half of the 20th century there were 9 federal hydroelectric installations and 17 operated by nonfederal and private agencies, with a total capacity of 500,548 kw. The basin program includes 36 federal installations, with a total capacity (including the 17) of 3,000,000 kw. By states their distribution is: Montana 8, North Dakota 6, Wyoming 5, South Dakota 3, Colorado 3 and Kansas 2.

**Floods.**—The paucity of large cities in the basin probably reduces the news value of Missouri basin floods to eastern newspapers. However, on the 6,000,000 ac. of agricultural land subject to flood, the federal government has reported damage of $200,000,000 in a single year. Visible manifestations of attempts to alleviate the flood problem are the huge dams and reservoirs which have been constructed, nearly all of them on the Missouri. Among them are Fort Peck, Garrison, Fort Randall, Oahe, Gavins Point, Harlan County (Republican River) and Lake of the Ozarks. (*See* also DAM.)

**Mineral Resources.**—Historically the mining centre of the Missouri basin has been the Black hills, where gold, silver and lead have been mined since 1874. Bituminous coal and lignite are mined at several places in North Dakota, Montana and Wyoming. A relative newcomer to basin mining is in northern Montana and North Dakota where the big Beaver Lodge and Tioga petroleum fields are developing in the Williston basin lying athwart the international border.

**Manufacturing.**—Except for Denver, dominant manufacturing city in the Missouri basin, the industrialization of the region has been based upon the conversion of the agricultural surplus. The production of flour, beet sugar, stock feeds, meat, leather, canned fruit and dairy products are most widespread. The manufacture of cement is established at a few places, and a beginning has been made in petroleum refining and petrochemical products. With the established manufacturing of the east north central states and the rising importance of Denver and Salt Lake City, the prospect for industrialization in the thinly populated Missouri basin is not great. *See* also UNITED STATES (OF AMERICA): *Physiography; Rivers and Harbours: Great Plains Province;* and references under "Missouri River" in the Index.

**MIST,** a light fog or hydrometeor (*q.v.*) which reduces horizontal visibility at the earth's surface to not less than 1 km. (⅝ mi.). The *International Cloud Atlas* (1956) defined mist as "a suspension in the air of microscopic water droplets or wet hygroscopic particles, reducing the visibility at the earth's surface." Mist forms a generally thin, grayish veil covering the landscape; the relative humidity is generally lower than 100%, and the air does not feel raw or clammy. In some parts of the United States drizzle (*q.v.*) is called "mist," as is haze (*q.v.*) in British countries. *See* FOG. (R. G. SE.; X.)

**MISTINGUETT** (stage name of JEANNE MARIE BOURGEOIS) (1873–1956), the most famous and popular French comedienne of her time. The daughter of an upholsterer, she was born at the village of La Pointe-Raguet, near Montmorency, on April 5, 1873. The name Mistinguett (Miss Tinguiett), derived from a song in a musical show, *Miss Helyett*, was suggested by her allegedly English-looking, protruding front teeth. Her greatest fame was achieved in Paris in spectacular revues at the Moulin Rouge and the Casino de Paris. She often partnered Maurice Chevalier, and her best-remembered songs are "C'est mon homme" and "J'en ai marre." She wrote two books: *Mistinguett and Her Confessions* (1938) and *Mistinguett, Queen of the Paris Night* (1954). After a long career, during which she appeared in London and toured the Americas, she died at Bougival, near Paris, on Jan. 5, 1956.

Mistinguett was not highly talented as a dancer, nor did she have a good voice, but she had vitality, conviction, a winning personality and a pair of legs celebrated for their beauty; even in old age she was able to play young parts.

**MISTLETOE,** common name for many species of semiparasitic green plants belonging to the Loranthaceae (*q.v.*) or mistletoe family. In Europe the commonly known species, the traditional mistletoe of literature, is *Viscum album*, found native from Great Britain to northern Asia. In the U.S. the common mistletoes are in the genera *Phoradendron* and *Arceuthobium*.

JOHN H. GERARD

AMERICAN MISTLETOE (PHORADENDRON FLAVESCENS) PARASITIC ON VARIOUS DECIDUOUS TREES

Pliny the Elder is the authority for the reverence in which the mistletoe was held by the druids. Prepared as a draft, it was used as a supposed cure for sterility and a remedy for poisons. Later, the mistletoe became esteemed as a traditional Christmas decoration. In modern times branches of *Phoradendron flavescens*, especially those with berries, are gathered for sale during the Christmas holidays. The traditional mistletoe, bound in a religious and sentimental aura, gave rise to the pleasant custom of kissing under the mistletoe, thought by some to lead to inevitable matrimony.

**Traditional Mistletoe.**—In England *Viscum album* is most abundant on the apple tree and is rarely found on the oak. Poplars, willows, lindens and hawthorns are its favourite habitats. Mistletoe forms a drooping yellowish evergreen bush, two to three feet long, particularly noticeable in winter when it contrasts with the naked limbs of deciduous trees or with the deep green of evergreen trees serving as hosts. The thickly crowded, forking branches bear opposite leaves about two inches long and oval to lance shaped. Small flowers, male and female on different plants, yellower than the leaves, appear in late winter and soon give rise to white berries, which when ripe are filled with a viscous semitransparent pulp.

Most fruit-eating birds eat the berries and thereby distribute the seed; this is accomplished when the bird wipes its beak, to which seeds adhere, against the bark of a tree. The viscid pulp soon hardens, affording a protection to the seed; in germination the sucker root penetrates the bark of the susceptible host and establishes a connection through which nourishment and water are derived from the host (mistletoes, being green, manufacture some of their own food).

Mistletoes, one of the few groups of higher plants parasitic on both deciduous and evergreen trees and shrubs, are slow in growth but very persistent; their natural death is determined by the death of the host. Sometimes merely pests, they may, if abundant, kill desirable trees. They may be controlled by removing the brittle green growth as completely as possible.

**American Mistletoes.**—*Phoradendron flavescens*, very similar to the traditional mistletoe of Europe, occurs especially on deciduous trees from New Jersey to Florida and westward to Texas and Kansas. The larger *P. macrophyllum* grows in bushy clumps two to eight feet in diameter and parasitizes chiefly poplar and willow from Texas to central California. Along the Pacific coast *P. villosum* occurs chiefly on oak; *P. juniperinum*, with scalelike

leaves, grows on junipers and incense cedar; *P. bolleana*, with pearllike berries, occurs on cypress; and the mesquite mistletoe (*P. californicum*), with slender pendulous branches, parasitizes mesquite, creosote bush and cat's-claw. In eastern North America *Arceuthobium pusillum* is a very small parasite on coniferous trees. Many species of the genus *Loranthus* inhabit the tropical regions of the eastern hemisphere.

*See* also PLANT DISEASES: *Causes*.

**MISTRA** (MISTRAS), a ruined Byzantine city in Greece, built on a prominent spur of Mt. Taygetus 7 km. (4 mi.) W. of Sparta. Founded as a fortress in the Frankish principality of the Morea by Guillaume de Villehardouin in 1248–49, it was handed over to the Byzantine emperor Michael VIII Palaeologus in 1262 by the treaty of Constantinople. In 1348 it became the capital of the Byzantine despotate of the Morea, being ruled by members first of the Cantacuzeno family (1348–80) and then of the Palaeologan dynasty (1382–1460). Mistra was the lively centre of a brilliant court life, comparable to that of contemporary Renaissance cities in Italy. Its shining ornament was the Neoplatonist George Gemistus Pletho (*q.v.*). Mistra was handed over to the Turks in 1460 and became their administrative centre for the Morea.

It declined in numbers and importance after its occupation by the Venetians (1687–1715) and was already practically deserted when Greece won independence from Turkey in 1829. The few remaining families were evacuated in 1952 because Mistra became an archaeological area, but the Pantanassa, a small convent for women, is still inhabited. Fine Byzantine frescoes survive in the chief churches: the cathedral (metropolis) of St. Demetrius, SS. Theodore and the Aphentiko (both belonging to the former convent of Brontocheion), Hagia Sophia, Peribleptos and Pantanassa. Many other buildings remain, including the walls of the palace of the despots, and the ruined Villehardouin fortress crowns the hill.

**MISTRAL, FRÉDÉRIC** (1830–1914), Provençal poet, the leader of the 19th-century revival of Provençal language and literature, who was awarded the Nobel prize for literature in 1905, was born at Maillane (Bouches-du-Rhône), on Sept. 8, 1830. His father was a well-to-do farmer and he was given a good schooling at the Collège Royal of Avignon (later renamed the Lycée Frédéric Mistral), where he had Joseph Roumanille (*see* PROVENÇAL LITERATURE) as teacher. He took a degree in law at the University of Aix in 1851. Wealthy enough to live without following a profession, he early decided to devote himself to the rehabilitation of Provençal life, and especially of the language, and this, with his literary activities, was his main occupation throughout a long life. In 1854, with several friends, he founded the *Félibrige*, an association for the maintenance of the Provençal language and customs, extended later to include the whole of southern France ("le pays de la langue d'oc"), and was its chief organizer and inspirer till his death at Maillane, on March 25, 1914.

Galled by the contempt in which Provençal was held and inspired by its past glories when, as the language of the Troubadours (*q.v.*), it was the cultured speech of southern France and was used by poets in Italy and Spain, Mistral threw himself into the literary revival of *langue d'oc* which was taking place all over the south of France. His charm, intelligence, commanding presence and great poetic gifts soon placed him at its head in Provence itself, and eventually throughout the Midi. By encouraging the composition of prose and verse in the language, by publishing popular magazines and almanacs, by organizing local games and dance and costume festivals, he sought to restore to the Midi the sense of nationhood which he claimed it had once possessed and which had been crushed by the tyrannical influence of Paris as the centre of culture. He based his activity on the countryside, where the language was most alive, but centres were established also in the towns. He undertook the preparation of a scholarly dictionary of *langue d'oc*, *Lou Tresor dóu Felibrige* (2 vol., 1878), to which he devoted some 20 years' work.

His poems were only one aspect of his campaign for Provençal culture, but it is as a poet that he is remembered. His attempts to restore *langue d'oc* to its ancient position were not entirely successful, but his poetic genius has given it some enduring masterpieces and he is one of the greatest of French poets.

His literary output consists of four long narrative poems: *Mirèio* (1859), *Calendau* (1867), *Nerto* (1884), *Lou Poèmo dóu Rose* (1897); a historical tragedy, *La Reino Jano* (1890); two volumes of lyrics, *Li Isclo d'or* (1875; definitive edition 1889) and *Li Oulivado* (1912); and many short stories, collected in *Proso d'Armano* (three volumes, 1926–29). His first narrative poem *Li Meissoun*, written in 1845, was posthumously published in the *Revue de France* (July–Aug. 1927). His volume of memoirs, *Moun espelido* (*Mes origines*, 1906; English translation 1907), is his best-known work, but his claim to greatness rests on his first and last long poems, *Mirèio*, and *Lou Poèmo dóu Rose* (Eng. trans. *The Song of the Rhône*, 1937), both full-scale epics in 12 cantos. *Mirèio*, which is set in the poet's own time and district, is the story of the love of a rich farmer's daughter and a poor basketmaker's son, thwarted by the girl's parents and ending with her death in the church of Les Saintes-Maries-de-la-Mer. Into this poem Mistral poured his love for the countryside where he was born. Narration, dialogue, description and lyricism are skilfully combined, and the poem is a blend of spontaneity and artistry, most clearly perceptible in the springy, musical quality of its highly individual stanaic form. The vivid evocations of the landscape, and of the moments of each day and of the seasons of the year make this love story also a great nature poem. Its idealization of people and places is never allowed to become excessive and it avoids the weakness and falsity of much pastoral literature.

*Lou Poèmo dóu Rose* is about navigation on the Rhône about 1830, just before the introduction of steam. The poem moves downstream from Lyons to Beaucaire with the barge "Lou Caburle," on board which there come, at different stages of the voyage, a romantic young prince of Holland and the daughter of a poor ferryman. The romance between them is cut short by the disaster which closes the poem, when the first steamboat to sail on the Rhône accidentally sinks "Lou Caburle" and, though the crew swims ashore, the lovers are drowned. The poem is written in unrhymed lines of ten syllables, a verse of great strength and variety. Less musical and more dense in style than *Mirèio*, this epic is just as full of life and colour. It reflects, however, a feeling of longing and loss; though it is not a confession of personal failure, an intuition grows upon the reader that Mistral, as he looks back, realizes that his aim has not been reached and that much of what he loves is, like his heroes, doomed to perish.

Mistral's lyrics, impersonal in their themes for the most part, include some exceptionally beautiful songs.

BIBLIOGRAPHY—C. M. Girdlestone, *Dreamer and Striver: the Poetry of Frédéric Mistral* (1957); N. Decrempe, *Mistral, maçe de l'Occident* (1954); R. Lafont, *Mistral ou l'illusion* (1954). (C. M. G.)

**MISTRAL, GABRIELA** (1889–1957), pseudonym of LUCILA GODOY ALCAYAGA, Chilean poet, who won the Nobel prize for literature in 1945, was born in Vicuña, Chile, April 7, 1889. Her prize winning "Sonetos de la Muerte" ("Sonnets of Death") made her poetic ability known in 1914. *Desolación* (1922) includes "Dolor"—the aftermath of a love affair tragically ended by the suicide of her lover. *Ternura* (1924, enlarged in 1945) and *Tala* (1938) evidence a broader interest in mankind; but love—of children, the downtrodden, nature and God—remained her principal theme. Her verse, more often virile than feminine and frequently coloured by figures and words peculiarly her own, is characterized by great warmth of feeling and strong emotional power, but in the poems for children there is a haunting, wistful strain of maternal tenderness. Her poetry has been translated into English, French, Italian, German and Swedish. Her prose is simple, discreet, and at times tense with emotion, but does not surpass her verse. She died on Jan. 10, 1957, at Hempstead, N.Y.

**MISTRAL:** *see* WIND: *Local Winds*

**MITCHAM,** a borough of Surrey, Eng., which under the London Government Act 1963 was to be amalgamated on April 1, 1965, with the borough of Wimbledon and the urban district of Merton and Morden to form the new London borough of Merton (*see* LONDON). Mitcham borough (1934) is a residential area with some light industries 8 mi. S. of Charing Cross. Pop. (1961) 63,653. Area 4.6 sq mi. Mitcham is a parliamentary constituency. It is mentioned in Domesday Book as Mitchelham. In the 18th and 19th centuries it was known for its cultivation of lavender and peppermint.

**MITCHELL, DONALD GRANT** (1822–1908), U.S. author, won his greatest vogue by blending the moods of gentle fancy and tender sentiment which characterized popular taste in the 1850s, making his pseudonym, "Ik Marvel," a household name. Born in Norwich, Conn., April 12, 1822, he graduated from Yale in 1841, and was U.S. consul at Venice, Italy (1853–54). His best known books, *Reveries of a Bachelor* (1850) and *Dream Life* (1851), occupy the border line between fiction and essay. Their evocation of rural delights, their treatment of youthful love and sorrow, and their escapism to a dream world have perennial charm. Most significant among his later works are *My Farm at Edgewood* (1863), recording his interest in agriculture, and *Dr. Johns* (1866), a novel reflecting his religious liberalism.

*See* Waldo H. Dunn, *The Life of Donald G. Mitchell* (1922).
(H. R. Bs.)

**MITCHELL, JOHN THOMAS WHITEHEAD** (1828–1895), a dominant figure in the English co-operative movement, was born in Rochdale, Lancashire, Eng., on Oct. 18, 1828. Becoming interested in the co-operative movement at an early age, he joined the Rochdale Society of Equitable Pioneers in 1853 and was appointed its secretary in 1857. He shaped the policy of the Co-operative Wholesale society, which was established in 1863, and was its chairman from 1874 until his death at Rochdale on March 16, 1895.

Mitchell's great contribution was to crystallize the concept of consumer's co-operation. He emphasized the fundamental importance of the role of the consumer, and his ideas constitute the theoretical and practical basis of the co-operative movement in Great Britain. An essential feature of the Rochdale system, which was subsequently adopted in many other countries, was the return of dividends on all purchases to members of the society. *See* also CO-OPERATIVES.

(GA. S.)

**MITCHELL, MARGARET** (1900–1949), U.S. novelist, author of *Gone With the Wind*, was born in Atlanta, Ga., in 1900. She attended Washington seminary in Atlanta and Smith college, Northampton, Mass. Called back from college by her mother's death, she wrote for the *Atlanta Journal* from 1922 until, in 1926, an ankle injury forced her retirement from the paper. It was then that she began to write her one book, *Gone With the Wind*, a novel about the American Civil War and the Reconstruction as seen from a southern point of view. She worked on the book for ten years, and it was published in June 1936. In 1937 Miss Mitchell received the Pulitzer prize for fiction. After the motion-picture rights were sold for $50,000, the picture made from the novel received an Academy award in 1940.

*Gone With the Wind* was almost certainly the largest selling novel in the history of U.S. publishing. A million copies were sold in the first six months after its publication, 50,000 of them in one day. Two million copies had been sold in the U.S. by 1939, and over 8,000,000, in 40 countries, before her death.

Margaret Mitchell married John R. Marsh in 1925. She died on Aug. 16, 1949, after having been struck by an automobile in Atlanta.

**MITCHELL, MARIA** (1818–1889), U.S. astronomer who made photographs of the sun and a special study of Jupiter and Saturn, was born on Nantucket Island, Mass., Aug. 1, 1818. In 1865 she became professor of astronomy and director of the observatory at Vassar college; and in 1888 professor emeritus. She died at Lynn, Mass., on June 28, 1889.

*See* Phebe Mitchell Kendall, *Maria Mitchell: Life, Letters and Journals* (1896); Helen Wright, *Sweeper in the Sky* (1949).

**MITCHELL, REGINALD JOSEPH** (1895–1937), British aircraft designer who produced the Spitfire fighter, was born at Talke, near Stoke-on-Trent, Staffordshire, on May 20, 1895. He was apprenticed to an engineering firm at Stoke and, after a period as assistant engineer there, joined the Supermarine Aviation works at Southampton in 1916, becoming chief engineer and designer in 1920. In 1922 he collaborated with Hubert Scott-Paine in producing a flying boat which won the Schneider trophy. Continuing this collaboration, he designed a number of marine craft ranging from large flying boats to small racing float seaplanes. In 1925 his S-4 floatplane raised the world speed record to 226.752 m.p.h. and in 1927, 1929 and 1931 his aircraft won the Schneider trophy on three successive occasions.

In 1931, Flight Lieutenant Stainforth raised the world speed record to 407.5 m.p.h. in Mitchell's S-6B. Mitchell's last aircraft was the famous eight-gun Spitfire fighter (1936) which contributed much to victory in the battle of Britain during World War II, and of which nearly 19,000 were built. He died at Southampton on June 11, 1937.
(D. CR.)

**MITCHELL, SILAS WEIR** (1829–1914), U.S. physician and author, who excelled in novels of psychology and historical romance, was born in Philadelphia, Pa., Feb. 15, 1829. He studied at the University of Pennsylvania and Jefferson Medical college (M.D., 1850), both in his native city. As an army surgeon during the American Civil War he became interested in nervous diseases, and was soon renowned for his "rest cure." In 1866 he published "The Case of George Dedlow," a story notable for its psychological insights and realistic war scenes. He wrote some 170 medical monographs on topics ranging from snake venom to neurasthenia, doing valuable pioneering work in several fields. *Wear and Tear* (1871) and *Fat and Blood* (1877), medical popularizations, were best sellers.

Mitchell also wrote juvenile stories, verse and prose fiction. Perhaps his most notable works are: *Roland Blake* (1886); *Hugh Wynne* (1898); *The Adventures of François* (1899); *Circumstance* (1901); *Constance Trescott* (1905); and *The Red City* (1907). His complete works were published as "The Author's Definitive Edition" in 16 volumes (1913–14). Mitchell died in Philadelphia, Jan. 4, 1914.

*See* Anna Burr, *Weir Mitchell: His Life and Letters* (1929); E. P. Earnest, *S. Weir Mitchell: Novelist and Physician* (1950); David Rein, *S. Weir Mitchell as a Psychiatric Novelist* (1952).

**MITCHELL, SIR THOMAS LIVINGSTONE** (1792–1855), British explorer of Australia, was born at Craigend, Stirlingshire, Scot., on June 16, 1792. A distinguished surveyor in the Peninsular War, he was appointed surveyor general of New South Wales in 1828. Mitchell explored northern and western New South Wales (1831 and 1835); discovered "Australia Felix," the western district of Victoria (1836); and attempted to travel overland from Sydney to the Gulf of Carpentaria (1845–47). He published the journals of his explorations (1838), an Australian geography (1851), texts on surveying and military exercises and a translation of *Os Lusiadas* by L. de Camões (1854). He was knighted in 1839, and died in Sydney on Oct. 5, 1855.
(T. M. Py.)

**MITCHELL, WESLEY CLAIR** (1874–1948), U.S. economist, who made pioneering studies of the money economy and became the world's foremost authority on business cycles, was born in Rushville, Ill., on Aug. 5, 1874. He attended The University of Chicago, where he came under the influence of Thorstein Veblen and John Dewey. Though his life was devoted primarily to economic research, he also taught economics at various universities, principally at Columbia.

In 1920 Mitchell helped to organize the National Bureau of Economic Research and was its director of research until 1945. He served as chief of the price section of the War Industries board during World War I, as chairman of Pres. Herbert Hoover's Research Committee on Social Trends, as a member of the National

Planning board in 1933 and of the National Resources board in 1934–35. For many years Mitchell played a leading role in the Social Science Research council and the Bureau of Educational Experiments. Under his leadership quantitative studies of economic behaviour developed rapidly in the United States and abroad. Mitchell died in New York city on Oct. 29, 1948.

Among his publications are *Business Cycles* (1913), *Business Cycles: the Problem and Its Setting* (1927), *The Backward Art of Spending Money and Other Essays* (1937) and *Measuring Business Cycles*, with A. F. Burns (1946). (A. F. Bs.)

**MITCHELL, WILLIAM** (1879–1936), U.S. army officer, pioneer in military aviation, was born Dec. 29, 1879, in Nice, France, of American parents. His father, John Lendrum Mitchell, later became U.S. senator from Wisconsin. Young Mitchell attended Racine college in Wisconsin and Columbian (later George Washington) university in Washington, D.C. He left college to enlist as a private in the infantry at the outbreak of the Spanish-American War in 1898. Shortly after, he received a commission as a second lieutenant in the signal corps and embarked on a military career that lasted for more than a quarter of a century.

Mitchell served in Cuba, the Philippines and Alaska and in 1909 he graduated from the Army Staff college at Ft. Leavenworth. In 1915 he was assigned to the aviation section of the signal corps. He learned to fly during the winter of 1915–16 at a school located in Newport News, Va., to which he commuted on week ends from Washington. When the U.S. entered World War I, Mitchell was already in Europe as an observer. By the time Gen. John J. Pershing arrived in France as commander of the American expeditionary forces on July 4, 1917, Mitchell had become the best-informed American aviation officer in Europe.

Always a man of action, Mitchell became the outstanding U.S. combat air commander of the war. In Sept. 1918 he commanded a French-U.S. air armada of almost 1,500 planes, the largest concentration of air power up to that time. This powerful force helped the U.S. 1st army wipe out the St. Mihiel salient. In the subsequent Meuse-Argonne campaign, Mitchell, promoted to brigadier general in Oct. 1918, used formations of up to 200 planes for mass bombing of enemy targets. His aggressive tactics reflected not only his character but also his ideas on the use of air power. In the latter, he was influenced by the great British air commander Maj. Gen. Hugh Trenchard, the foremost advocate and practitioner of strategic air bombardment during World War I.

Mitchell returned to Washington after the war to be appointed assistant chief of the air service in 1919. He became a strong proponent of an independent U.S. air force and of unified control of air power, both of which were opposed by the army general staff and the navy. Mitchell challenged the concept of the navy as the first line of defense and mobilized congressional and public opinion to induce the navy to permit him to carry out bombing tests against old battleships. In July 1921 he commanded air service bombers that sank the former German dreadnought "Ostfriesland" in 21½ minutes off the Virginia coast. When air service bombers sank two obsolete U.S. ships in tests off Cape Hatteras in Sept. 1923, the navy took the lesson to heart and began to build its forces around the aircraft carrier.

As Mitchell's hopes for recognition and appreciation of the future of air power failed to materialize, he became increasingly outspoken in his criticism of the military hierarchy that did not accept his views. At the expiration of his term as assistant chief of air service in April 1925 he was sent to San Antonio, Tex., in his permanent grade of colonel, as air officer of the 5th corps area. But this departure from the seat of government did not silence him; he continued to write and speak in behalf of his views. The climax came in Sept. 1925 when the loss of the navy dirigible "Shenandoah" in a storm inspired Mitchell to publicly accuse the war and navy departments of "incompetency, criminal negligence and almost treasonable administration of the National Defense." In Dec. 1925 an army court-martial convicted him of insubordination. Sentenced to suspension from rank and duty for five years, he resigned from the army as of Feb. 1, 1926, and devoted the remaining ten years of his life to propagating his gospel of air power.

Mitchell died Feb. 19, 1936. He did not witness the vindication of much that he stood for. Had Mitchell lived through World War II he would have seen the fulfillment of many of his prophecies of air warfare: strategic bombardment, mass air-borne operations, the strategic importance of Alaska and the polar areas and the eclipse of the battleship by the airplane. During his life he was awarded many decorations and honours both by his own and other countries. In 1946 congress authorized a special medal in his honour; it was presented to Mitchell's son in 1948 by the chief of staff of the newly created U.S. air force.

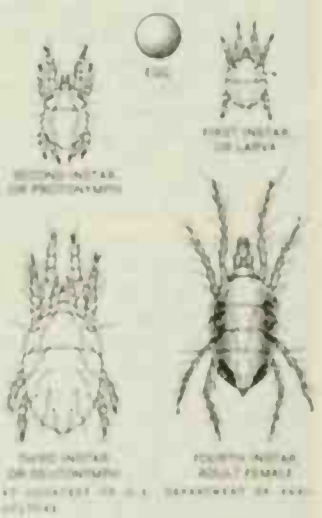
**MITCHELL, MOUNT,** a peak of the Black mountains, a short cross range extending north from the Blue Ridge through Yancey county, North Carolina, and a part of the Appalachian mountain system. It is the highest (6,684 ft. above sea level) peak in the United States east of the Mississippi river. In the same region there are about a dozen summits above 6,000 ft., the noblest of them being Blackstock Knob (6,359 ft.), Big Craggy Mount (6,105 ft.) and Balsam Cone (6,611 ft.). The mountains of North Carolina were not subject to glaciation and are, therefore, covered with a mantle of soil to the top, except for rocky precipices. They are covered with hardwood and pine forests in the lower elevations, and in the upper parts with an unbroken mantle of spruce and balsam.

*See* also BLUE RIDGE; APPALACHIAN MOUNTAINS.

**MITCHELSTOWN** (BAILE AN MHISTEALAIGH), a town and agricultural centre of County Cork, Republic of Ireland, lies southwest of the Galtee mountains and 32 mi. N.E. of Cork city by road. Pop. (1961) 2,655. It has large creameries with ancillary industries manufacturing cheese (Galtee) and chocolate crumb.

The Mitchelstown caves, about 8 mi. N.E. in County Tipperary, are among the finest limestone caves in the British Isles. They extend for miles underground and are divided into two groups—the double-chambered Old or Desmond caves (where the earl of Desmond hid in 1601) and the New caves discovered in 1833. The latter are a maze of galleries and chambers, with names such as the House of Lords, Lot's Wife, etc., containing stalactites and stalagmites. (A. McC.)

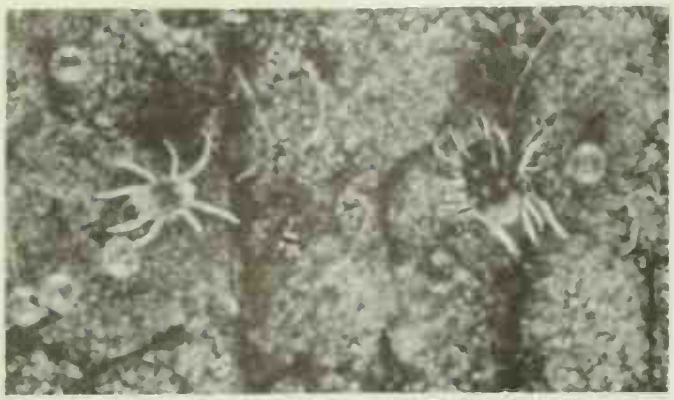
**MITE,** any of the small spider relatives that constitute several orders of the Acarina (Acari), a subclass of arachnids that includes also the ticks (*see* ARACHNIDA for another classification). The Acarina live in varied habitats, being found in brackish water, fresh water, hot springs, in soil and on plants, and are parasitic on and in animals. Some of the parasitic kinds may be found in such diverse habitats as the nasal passages, lungs, stomach and deeper body tissues. A few of the mites, and many of the ticks, are carriers of diseases to man and animals, and can cause enormous losses, especially in the case of ticks transmitting cattle diseases. Plant-feeding mites cause damage by feeding on the leaf tissues, or by transmitting virus diseases to the plants.



LIFE STAGES OF A COMMON RED SPIDER MITE, TETRANYCHUS TELARIUS

The Acarina are distinguished by small size (mites up to ¼ in.; ticks to about 1½ in.), and a non-segmented body, in which the head, thorax and abdomen are broadly joined, only the mouth-parts being separate. There are usually four pairs of legs. In general mites and ticks breathe by means of air tubes or tracheae, although many have no breathing apparatus and respiration takes place through the skin alone.

Although mites have been known since the time of Aristotle,



EUROPEAN RED MITE (PANONYCHUS ULMI): EGGS, YOUNG AND ADULTS ON UNDERSIDE OF APPLE LEAF

they were studied only sporadically until World War II, when mite-borne scrub typhus caused sickness and death to the troops in the south Pacific. Also, interest has been spurred because insecticides such as DDT have eliminated many mite and insect predators, and have fostered the development of acaricidal resistance. Furthermore some mites are carriers of virus diseases of important crops such as wheat and peaches.

The subclass Acarina may be divided into seven orders, the Notostigmata, Tetrastigmata, Metastigmata, Mesostigmata, Cryptostigmata, Astigmata and Prostigmata.

The Notostigmata and Tetrastigmata consist of a few species of primitive mites of no economic importance to man.

The Metastigmata comprises the ticks (*q.v.*).

The Mesostigmata, a large group, includes the well-known chicken mite, the northern fowl mite and the rat mite (all of which will attack man), the nasal mites of dogs and birds, the lung mites of monkeys and the predatory mites found on foliage of trees and plants. These predatory mites are at times of great benefit in controlling plant-feeding mites.

The Cryptostigmata (beetle mites) occur in soil and humus, and occasionally on tree trunks and foliage. In general, they are not considered harmful, and may play a significant role in the breakdown of organic matter, since they constitute a large part of the soil fauna. A few species transmit tapeworms to ruminants; the mite ingests the tapeworm egg and is then in turn eaten along with herbage by stock.

The Astigmata contains the grain and cheese mites (Acaridae), itch mites (Sarcoptidae) of man and animals, scab mites (Psoroptidae), feather mites of birds, mites associated with insects and many free-living forms. Grain mites not only damage stored products but can also cause dermatitis to handlers of infested products. Itch mites burrow into the dermal layers of the skin of man, as well as into the hides of dogs, pigs, sheep and goats, causing injury. Scab mites are found on sheep and cattle, sometimes causing serious injury. Others are found in the air sacs of bird lungs, or in the nasal passages and stomach of bats.

The Prostigmata contains the plant-feeding mites and the chiggers, as well as many predators; it is a large group found in soil, on plants and as parasites of animals. These mites may have from one pair of degenerate legs to the usual four pairs. The bud or gall mites (Eriophyidae), about $\frac{1}{150}$ of an inch long, cause injury to plants either by distortion of leaves and fruit through injection of a toxin, by damaging leaves by feeding, or by transmitting a virus that kills the plant. An infestation of common plant-feeding spider mites or "red spiders" (Tetranychidae) can, at times, completely defoliate the hosts; this family is becoming increasingly difficult to control because of the development of resistance to acaricides. Of great interest to man are the harvest mites or chiggers (Trombiculidae), which cause irritation by their bites, both to man and animals, or sickness or death to man by transmitting tsutsugamushi disease or scrub typhus in the far east and south Pacific (see TYPHUS FEVER). The chigger (*q.v.*) is of interest biologically because only the larval form is parasitic, the nymphs and adults being predaceous on small arthropods and their eggs. In this order are some tiny wormlike follicle mites (Demodicidae) that live in the pores of man and animals, at times causing irritation, and in the case of domestic animals, serious injury or death if not treated. A large group of prostigmatic mites live in fresh water (Hydrachnidae, Limnocharidae, Eylaidae, etc.) and can be found in lakes, streams and hot springs; another group (Halacaridae) is found in brackish water along the coasts.

*See* also ARACHNIDA and references under "Mite" in the Index.

**MITFORD, MARY RUSSELL** (1787–1855), English dramatist, poet and essayist, chiefly remembered for her delightful sketches of village life, was born at Alresford, Hampshire, on Dec. 16, 1787. She was the only daughter of George Mitford, a dashing, irresponsible character fond of fast living, whose extravagance compelled the family, in 1820, to leave their house in Reading (built when Mary, at the age of ten, won £20,000 in a lottery) for a labourer's cottage in the nearby village of Three Mile Cross. Thereafter, until his death in 1842, his daughter struggled to provide for him and to pay his gambling debts out of her literary earnings. In 1810 she published *Miscellaneous Poems* (2nd ed., 1811); her narrative poem *Christina* (1811) was revised by Samuel Taylor Coleridge, who inserted some lines; other volumes of mild romantic verse followed. She then turned to the theatre, with some success, her greatest triumph being *Rienzi*, which had 34 performances at Drury Lane in 1828 and also met with acclaim in the United States. An unrelieved blank verse tragedy in classical style, it still has power.

Her reputation, however, rests on the sketches that fill the five volumes of *Our Village* (1824–32; ed. by Sir John Squire, Everyman's Library, 1936). These sketches, based on her observation of life in and around Three Mile Cross, catch the pleasant atmosphere of the English countryside and the quaintness of village characters. As Elizabeth Barrett Browning wrote, "through all the beauty there is a clear vein of sense, and a quickness of observation. . . ." But the unpleasant aspects of country life are omitted.

In the last volume of *Our Village* and in the ensuing books—the best of which are *Belford Regis* (1835), a picture of Reading, and *Country Stories* (1837)—there are signs of exhaustion, and the wit is replaced by a gentler humour. However they do contain numerous passages that illuminate English provincial life in the late 18th and early 19th centuries.

Her friends included Coleridge, Charles Lamb and, in later life, Elizabeth Barrett Browning. She considered letter writing an art, and some of her delightful correspondence survives in the *Life* (1870, ed. by A. G. K. L'Estrange) and the *Letters* (1872, ed. by H. Chorley). Her *Recollections of a Literary Life* (1852), intermingles pleasant chat about her favourite books with autobiography. In 1837 she received a civil list pension. She died at Swallowfield, near Reading, on Jan. 10, 1855.

**MITHILA,** an ancient city and a medieval kingdom of India. The city (perhaps modern Janakpur in southern Nepal) flourished in the time of the Upanishads and during the period described by the *Ramayana*, perhaps the 8th and 7th centuries B.C. It was the capital of Videha, a kingdom which at its greatest extent lay between the Ganges river and the Himalayas, the Gandak and the Kosi rivers in northern Bihar and southern Nepal. It had been swampland before its colonization by the Aryan tribes who built Mithila, and the city prospered, owing partly to the fertility of the region. To the court of King Janaka came Yajnavalkya and other Upanishadic philosophers; and Sita, heroine of the *Ramayana*, was the daughter of a King Janaka of Mithila, a city then well-planned and spacious, boasting of beautiful gardens and buildings. The early kings of Mithila claimed descent from the sun through Ikshvaku. By the 6th century B.C. the Videhas had

formed an aristocratic republic, and had joined a confederacy of republican tribes, the Vajjis, whose boundaries were those of greater Videha. They were subjugated about 450 B.C. by Ajatasatru of Magadha. The old city decayed, and Mithila in later times was a name of greater Videha, also known as Tirabhukti (modern Tirhut), long noted for its conservatism and the learning of its Brahmans. Among its rulers were a learned dynasty of Brahman kings who reigned from the 14th to the 16th centuries; at the court of the most famous, Siva Simha, Vidyapati (fl. A.D. 1400) wrote the Maithili lyrics still sung in northeastern India.

(R. THI.)

**MITHRADATES,** less correctly MITHRIDATES, a Persian name derived from Mithra, the sun-god, and the Indo-European root *da*, "to give," *i.e.*, "given by Mithra." The name occurs also in the forms Mitradates and Meherdates. It was borne by a large number of oriental kings, soldiers and statesmen. The most important are three kings of Parthia of the Arsacid dynasty (*see* PERSIAN HISTORY: *Parthian Empire*) and six kings of Pontus (*q.v.*). There were also three kings of Commagene, two of the Bosporan kingdom and one of Armenia (A.D. 35/36–51).

**Kings of Parthia.**—MITHRADATES I (Arsaces VI), successor of his brother Phraates I, came to the Parthian throne at an uncertain date between 174 and 160 B.C. Before 160 he seized Media from Timarchus, who was the governor of the eastern provinces of the Seleucid empire. Turning to the east he won two provinces from the Bactrian king Eucratides (*q.v.*). After conquering Elymais he occupied Babylonia (142 or 141 B.C.); by this time he controlled most of the former Seleucid satrapies to the west of Bactria as far as the border of Mesopotamia. The Seleucid king Demetrius (*q.v.*) II Nicator recaptured Babylon (141 or 140 B.C.) but was defeated and made prisoner shortly afterward; Mithradates detained him in honourable captivity, giving him his daughter Rhodogune in marriage. Mithradates died about 138. Diodorus Siculus praised him as a mild ruler; and the fact that from 140 his coins carry the epithet *philhellen*, "Greek-loving" (till then he only called himself "the great king Arsaces"), shows that he tried to conciliate his Greek subjects.

MITHRADATES II (*c.* 124–*c.* 87 B.C.) succeeded his father Artabanus, who was killed in battle against the Saca nomads invading Iran from the northeast. He recovered the eastern provinces that had been overrun by the Sacae, and, in the west, conquered Mesopotamia and defeated the Armenian king Artavasdes. The most successful and perhaps the greatest of the Parthian kings, he died about 87 B.C.

MITHRADATES III usurped the throne from his elder brother Orodes in 56 B.C. but was driven out the next year. He took refuge with the Roman governor of Syria, Aulus Gabinius. Returning to Parthia he was defeated and put to death (54).

**Kings of Pontus.**—The Mithradatids of Pontus were descendants of an ancient Persian noble family. The details of their origin and the system of numbering them have been involved in some obscurity since the loss of the historical works of Hieronymus of Cardia, on which classical writers relied. The following account conforms to the view of M. Rostovtzeff (*see Bibliography*).

MITHRADATES I, to whom (rather than to his son) the epithet CTISTES ("founder") seems to belong, was ruler of Cius on the Propontis (in succession, it is said, to two of his kinsmen, an earlier Mithradates and Ariobarzanes) from 337/336 B.C. till his death in 302/301. Suspected of treachery by Antigonus I Monophthalmus, he may have been escaping to the east with his son when he was killed.

MITHRADATES II, to whom scholars before Rostovtzeff commonly assigned the title Mithradates I Ctistes, was the son of the foregoing. Warned by his friend Demetrius Poliorcetes, the son of Antigonus, that he had incurred the same disfavour as his father, he fled to Paphlagonia, where he seized Cimiata, a fort at the foot of the Olgassys range (modern Ilgaz Daglari). Joined by the Macedonian garrison and by neighbouring populations, he conquered Cappadocian and Paphlagonian territories on both sides of the Halys river to form the nucleus of his kingdom of Pontic Cappadocia or Pontus (*q.v.*). He died in 266/265 B.C., leaving the kingdom to his son Ariobarzanes.

MITHRADATES III was very young when he succeeded his father, Ariobarzanes (*c.* 255 B.C.). Early in his reign the Gauls of Galatia (*q.v.*) invaded Pontus. Mithradates was at the battle of Ancyra (*c.* 240), in which he assisted Antiochus (*q.v.*) Hierax against the latter's brother, the Seleucid king Seleucus II Callinicus. His wife, their sister Laodice, had brought him Greater Phrygia as her dowry; and his daughter, also named Laodice, married a later Seleucid king, Antiochus (*q.v.*) III. He attacked Sinope (Sinop) (*c.* 220) but it was not taken until after his death (*c.* 185). His son and successor Pharnaces I took Sinope (183), which he made the capital of the kingdom instead of Amasya (Amasia), and tried also to extend his power into the Tauric Chersonese (Crimea).

MITHRADATES IV PHILOPATOR PHILADELPHUS, a younger son of Mithradates III, may have reigned for a time conjointly with his brother Pharnaces and then occupied the throne in a form of regency (*c.* 170–*c.* 150) for the latter's son. He assisted Attalus II of Pergamum to resist Prusias II of Bithynia.

MITHRADATES V EUERGETES, the son of Pharnaces, appears to have become sole ruler of Pontus *c.* 150 B.C. At first a friend of the Romans, he sent them a contingent during the Third Punic War and helped them to get possession of Pergamum (bequeathed to them by Attalus III, but claimed by Aristonicus, a natural son of Eumenes II). Nicomedes II of Bithynia also helped the Romans in this affair (133–131 B.C.), and both he and Mithradates expected to be rewarded with Phrygia. A commission awarded it to Mithradates, but the Roman senate refused to ratify the bargain on the grounds of bribery. Mithradates appears to have taken Phrygia without waiting for a new award. He invaded Cappadocia and married his daughter to the young king Ariarathes VI Epiphanes. He acquired the succession of Paphlagonia from its last king, Pylaemenes, and obtained a kind of protectorate over Galatia. At the height of his power, in 121 or 120 B.C., he was assassinated by his courtiers during a banquet in his palace at Sinope.

MITHRADATES VI EUPATOR, called THE GREAT (d. 63 B.C.), succeeded his father Mithradates Euergetes *c.* 121 B.C. He was then only a boy and for a few years his mother ruled in his place. About 115 she was deposed and thrown into prison, and Eupator ruled alone. He began his long career of conquest by dispatching successful expeditions to the Crimea and to Colchis (on the eastern shore of the Black sea). Both districts were added to the Pontic kingdom. To the Greeks of the Tauric Chersonese and the Cimmerian Bosporus (Crimea and Straits of Kerch) Mithradates was a deliverer from their Scythian enemies and they gladly surrendered their independence in return for the protection given to them by his armies. In Asia Minor, however, the royal dominions had been considerably diminished after the death of Mithradates V.: Paphlagonia had freed itself, and Phrygia (*c.* 116 B.C.) had been linked to the Roman province of Asia. The king's first move there was to partition Paphlagonia and Galatia between himself and Nicomedes III of Bithynia; but next he quarreled with Nicomedes over Cappadocia. Successful at first on two occasions, he was on both deprived of his advantage by Roman intervention (*c.* 95 and 92). While appearing to acquiesce, he resolved to expel the Romans from Asia. A first attempt to depose Nicomedes IV of Bithynia, who was completely subservient to the Romans, was frustrated (*c.* 90). Then Nicomedes, instigated by Rome, attacked Pontic territory, and Mithradates, after protesting in vain to the Romans, finally declared war (88).

Nicomedes and the Roman armies were defeated and flung back to the coasts of the Propontis and the Aegean. The Roman province of Asia was occupied and most of the Greek cities in western Asia Minor allied themselves with Mithradates, though a few held out against him, such as Rhodes, which he besieged unsuccessfully. He also sent large armies into Greece, where Athens and other cities took his side. But the Roman generals, Sulla in Greece and Fimbria in Asia, defeated his forces in several battles during 86 and 85. In 88 he had arranged a general massacre of the Roman and Italian residents in Asia (80,000 are said to have perished), in order that the Greek cities, his accessories in the crime, should feel irrevocably committed to the struggle against Rome. As the war turned against him his former leniency toward the Greeks

changed to severity; every kind of intimidation was resorted to—deportations, murders, freeing of slaves. But this reign of terror could not prevent the cities from deserting to the victorious side. In 85 when the war was clearly lost he made peace with Sulla in the treaty of Dardanus, abandoning his conquests, surrendering his fleet, and paying a fine of 2,000 talents.

In what is called the Second Mithradatic War, L. Licinius Murena invaded Pontus without any good reason in 83, but was defeated in 82. Hostilities were suspended, but disputes constantly occurred, and in 74 a general war broke out. Mithradates defeated M. Aurelius Cotta, the Roman consul, at Chalcedon; but Lucullus worsted him outside Cyzicus (73) and drove him in 72 to take refuge in Armenia with his son-in-law Tigranes. After two great victories at Tigranocerta (69) and Artaxata (68), Lucullus was disconcerted by the defeat of his lieutenants and by mutiny. (*See* LUCULLUS, LUCIUS LICINIUS.) In 66 he was superseded by Pompey, who completely defeated both Mithradates and Tigranes. Mithradates established himself in 64 at Panticapaeum (Kerch) on the Cimmerian Bosporus and was planning an invasion of Italy by way of the Danube when his own troops, led by his son Pharnaces II, revolted. After vainly trying to poison himself, Mithradates ordered a Gallic mercenary to kill him. So perished (63 B.C.) Rome's greatest enemy in Asia Minor. His body was sent to Pompey, who buried it in the royal sepulchre at Sinope.

Mithradates was a man of great stature and physical strength, a brave fighter and a keen hunter. The ancient historians have invested him with a halo of romance and many strange stories are told of his life. Whatever their truth, there can be no doubt that he had some of the worst traits of the oriental despot, cruelty and sensuality in particular. On the other hand, it cannot be denied that he was a ruler of astonishing energy and determination, or that he possessed political skill of a high order. The fact that he was one of the few men to offer a serious challenge to the Roman republic is sufficient testimony to his ability. He organized the forces at his disposal very effectively and he had a good grasp of strategy. He was unlucky in having to face three exceptionally brilliant Roman generals; unlucky, too, in coming to power at a time when the Hellenistic world was in the final stage of its collapse. It is quite conceivable that had he been born a century earlier he could have constructed an enduring Greco-Asiatic empire after the fashion of the Parthian kings. A cunning, brutal tyrant, he concerned himself solely with maintaining and strengthening his own power. He posed as the champion of Hellenism, the "new Dionysus," but this was in furtherance of his political ambitions; it is no proof that he was deeply imbued with Greek culture or that he felt a mission to promote its extension within his domains. Hellenism made advances in Pontus during his reign, as it had under his predecessors, but this was a natural process. He treated all alike. Greek, Roman and Asiatic were welcome at his court provided that they could be of use to him (his military subordinates were mostly Greeks, though in later years he employed several Roman renegades); but he trusted no one. Just as it is impossible to speak of his favouring one religion or culture above another, so it is impossible to believe that he had any notion of bringing Greeks and Asiatics closer together in a new kind of political and social system. His posing as a liberator of the Greeks from Roman oppression and, later, his encouragement of social revolution in the Greek cities of the province of Asia were in both cases the actions of an opportunist seeking immediate political advantages.

**MITHRAISM,** the worship of the Indo-Iranian god of light Mithra (Sanskrit *Mitra*), which spread from Persia to Asia Minor and thence to Rome and many parts of the Roman empire. One of the last of the oriental mystery cults to reach the west, Mithraism was also one of the most vigorous, and in the final death struggle of paganism it emerged as a chief rival and opponent of Christianity.

**History.**—The position of Mithra in Iran, though greater than that of Mitra in Vedic India, held little promise of the god's future career in the west. He is not mentioned in the *Gathas*, which suggests that he was deliberately ignored in the monotheistic reforms of Zoroaster. Later Zoroastrianism found room for him, though only as subordinate to the supreme god Ormizd (Ahura Mazda). He appears with Ormizd and Anahita, the goddess of waters, in royal inscriptions of the 4th century B.C., and Achaemenid kings of the period seem to have regarded him as their special patron. The Avestan hymns, notably *Yasht* x, depict him as the god of heavenly light, all-seeing, the guardian of oaths, protector of the righteous in this world and the next, and above all as archfoe of the powers of evil and darkness and hence god of battles.

It was not, however, this national cult of Mithra that was to attract the west, but rather an amalgam, in effect a new creation, that sprang up abroad in the wake of the Persian conquests. The scanty information available does not make it possible to trace the development in detail, but it was almost certainly in eastern Anatolia, where Persian traditions survived longest, that the new religion took its definitive form. Babylonia contributed, as it did to most forms of late paganism, the fatal allure of its pseudo science, Chaldaean astrology, while Greek artists and Greek religion and philosophy provided the models, at least indirectly, for Mithraic iconography and the Mithraic mysteries. Yet despite its veneer of Hellenization, the cult had little appeal for Greeks, and only scattered traces are found in Greece and the Greek east.

A passage of Plutarch (*Pompey*, 24) may imply that the rites were first brought to the attention of the west by Cilician pirates captured in 67 B.C., but it was not until late in the 1st century A.D. that Mithraism took firm root in the west, and it began to expand rapidly only in the following century. Rome itself, and its seaport Ostia, always remained a great centre of the cult, which reached to Numidia in the south and as far north as the Roman wall in Britain. It was, however, in the Danubian provinces and along the Rhine that Mithra was most popular, apart from Rome; in western Gaul and the Spanish peninsula he seldom appears.

The new religion owed its diffusion primarily to the army, many of whose recruits were drawn from the Anatolian centres of Mithraic worship, and also to the traffic in oriental slaves; trade routes too played a part, since the stern probity of the god was attractive to the mercantile classes. The cult's chief appeal was at all times to the lowly and humble, and the influence and extent of imperial interest probably has been overemphasized by some scholars. The initiation of the emperor Commodus (A.D. 180–192) was a passing fancy without lasting effect. The institution by Aurelian (A.D. 274) of a state cult of the "unconquerable Sun," *Sol invictus*, may have contributed incidentally to the prestige of Mithra, who also bore this proud title, but Mithra never achieved a place in the public cults of the state, and it is not until *c.* 307, under Diocletian, that an imperial dedication to Sol Invictus Mithra, acclaiming him as "a protector of the empire," is found. Yet in fact Dacia, long a stronghold of Mithraism, had already been abandoned to the barbarians (*c.* 270)—the first Roman province to suffer this fate.

With the advent of the Christian emperors, imperial favour gave way to hostility and even to persecution. The victory of Theodosius in 394 effectively put an end to the cult, but not before the pagan revival under Julian the Apostate (360–363) and the final rally of the pagan aristocracy at Rome had for a few decades made the Persian god a principal symbol of the dying past.

**Monuments, Myth and Ritual.**—In the absence of liturgical works or extensive literary accounts, the interpretation of Mithraism depends chiefly on archaeological evidence, above all the sculptures that adorned the sanctuaries. Dedicatory inscriptions, in Latin or Greek, provide some significant details, and the polemic of Christian writers is often suggestive.

The Mithraic chapels, referred to as *spelaea* ("grottoes"), were sometimes actual caves, more often small underground crypts. A narrow aisle was flanked on both sides by a broad raised bench, on which the worshipers, rarely more than 50 in number, could kneel or recline. At one end, often apselike, stood the representation of Mithra slaying the bull, evidently the crowning episode in Mithraic myth and perhaps in the ritual. The scene normally

includes a pair of torch bearers flanking the central figures, a scorpion attacking the genitals of the bull, a serpent drinking its blood and a dog springing toward the wound in its side. Sun-god, raven (perhaps the messenger of the sun-god), tree, lion and ewer are sometimes added, and, framing the scene, the signs of the zodiac. Finally, this whole unit may be surrounded by a series of smaller panels, filled with mythical scenes or symbolic figures.

On the basis of the sculptures, eked out with references from the literature, attempts have been made to reconstruct the Mithraic theology and legend. Though probably subordinate both to the first principle, Zurvan Akarana (Infinite Time), and to Ahura Mazda, Mithra, as the creator and as mediator between man and the higher gods, was clearly the chief deity of the cult as practised. A curious lion-headed human figure, about which a serpent coils, has usually been identified as Zurvan Akarana, but it seems more likely that he is instead Ahriman, the power of death and darkness, who was perhaps regarded as the prince of this world. Mithra's own legend is depicted in detail, though the interpretation necessarily remains dubious. Among the events that appear certain are the birth of Mithra from a rock, his shooting an arrow at a cliff to bring forth water, his adventures in pursuit of the sacred bull, ending with his reluctant (?) sacrifice of the animal, his alliance with the sun-god, the banquet shared with him and his ascent to heaven in the chariot of the Sun. According to Persian sources the bull, apparently in origin a vegetation spirit, by its death gave birth to all living things; thus Mithra became the creator of life, as by his other exploits he was its protector against evil.

As to the organization of the mysteries, it is known that there were seven degrees of initiation open to the adept, perhaps corresponding to the seven planetary spheres to be traversed by the soul in its upward progress: *Corax*, Raven; *Nymphius*, Bridegroom; *Miles*, Soldier; *Leo*, Lion; *Perses*, Persian; *Heliodromus*, Courier of the Sun; *Pater*, Father. (Except that *Pater* is the highest and *Leo* somewhere in the middle, there is no certainty as to the order.) Those in the lowest ranks were called servants, those in the ranks of *Leo* and above, participants, perhaps with reference to the sacred meal of bread and water, which Christian writers likened to the Eucharist.

Initiation was open to men of all ages, even boys; women were excluded. Intensive purifications, including perhaps a sort of baptism, were prerequisite to initiation, and at each degree the initiate underwent certain ordeals, which however crude or fearsome were charged for him with symbolic meaning; thus the *Miles* was branded on the forehead, to mark him henceforth as a recruit in the army of Mithra, sworn to combat all evil. At the head of each group was either a *Pater* or priest. The latter was designated, in usual Roman fashion, as *sacerdos* or *antistes*; there is no hint of the Persian *magus* or anything resembling a priestly caste. Despite the fixity of the iconography and, presumably, of the doctrines, there was no ecumenical organization or hierarchy; at most in each large centre there was a *pater patrum*, as it were, an overseer or bishop. Since Mithraism never became, officially, a recognized cult of the Roman empire, the separate groups of worship remained, like other nonpublic cults, private associations, administered by their own nonclerical officials and supported by private contributions. The numerous dedications, together with the simplicity of the sanctuaries, attest the fervid piety of the worshipers and no less their prevailingly modest circumstances. In fact the cult knew no social distinctions, and slave, freeman, rich, poor, labourer and noble met here as equals.

Like the other oriental mystery religions, but perhaps with more cause, Mithraism offered the appeal of an exotic and ancient wisdom. It professed to explain the origins of the universe and also its end; and Mithra, who had created once and was now man's defender and helper, would in those final days inaugurate a new order in which the faithful would enjoy forever a blessed immortality. Mithra, like the other oriental gods, offered man deliverance, but unlike such others as Attis or Osiris he could also serve as an ideal, a heroic leader for man to follow and emulate in the struggle against evil. A vigorous and positive morality characterized Mithraism throughout its career and constituted one of its chief attractions.

"THE GOD MITHRA SACRIFICING A BULL." ROMAN BAS-RELIEF IN THE LOUVRE, PARIS (HEAD HAS BEEN RESTORED)

**Relations to Christianity.**—The oft-quoted opinion of Ernest Renan, that if the growth of Christianity had been stopped early in its history the world would have been Mithraic, has less value, perhaps, as a historical judgment than for its evocation of how the religious conflict might have seemed to a 3rd-century Christian or Mithraist. Superficially, at least, the two religions had much in common: a divine Lord by whose deeds, performed once (unlike the annual passion of an Attis or an Osiris), man was assured of salvation; a sacramental meal; a ritual of baptism; a concept of religion that could liken the religious life to enlistment and service under a divine commander, *militia Christi* or *militia Mithrae* (though in the case of Mithraism this perhaps did not imply the cosmic struggle between good and evil that appears in both Christianity and Zoroastrianism); not dissimilar ideas of heaven and hell and of a Last Judgment; and a moral code considerably higher and more rigid than that found in contemporary society or required by most other cults. It is not surprising that pious Christians regarded these traits of the rival religion as satanic inventions, parodies of the rites and beliefs of the true church. The last stages of paganism did indeed witness some conscious borrowing of Christian religious patterns, but the more deeply rooted similarities are best explained in terms of a common oriental background.

The similarities were in any case outweighed by the differences, and in these Christianity generally had the advantage. In a period when philosophic and popular thought was increasingly tending to monotheism, Mithraism, for all its exaltation of Mithra, was securely bound to its polytheistic traditions. Mithraism suffered, too, in comparison by having as its redeemer a mythical figure, whose appeal could never match that of the historical Jesus worshiped by Christians as God incarnate. And Mithraism was fatally weak in its exclusion of women. Its distribution, except in the metropolitan centres, is significant: it flourished chiefly where particular conditions, military or mercantile, created a "man's world," and it was weakest where ordinary civilian patterns prevailed. Mithraism failed to use the family as a source of religious strength and continuity. This failure may help to explain why, when the circumstances favourable to its growth at last changed, the imposing edifice of Mithraism collapsed so suddenly and disappeared with such surprising rapidity.

1900), his conclusions were also published separately as *Les Mystères de Mithra*, 3rd ed. (1913), 3rd German ed. with latest supplements (1923) and *Les Religions orientales dans le paganisme romain*, 4th ed., ch. vi (1929). Good surveys: H. Stuart Jones, "Mithraism" in Hastings, *Encyclopaedia of Religion and Ethics* (1915); E. Wüst, "Mithras" in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft* (1932). F. Saxl, *Mithras*, richly illustrated, supplements Cumont for the monuments (1931), as does M. J. Vermaseren, *Corpus Inscriptionum et Monumentorum Religionis Mithriacae*, vol. i (1956). Illustrations: in J. Leipoldt, *Die Religion des Mithra*, in Haas, *Bilderatlas zur Religionsgeschichte*, vol. xv (1930). Later studies: see references in M. P. Nilsson, *Geschichte der griechischen Religion*, vol. ii (1950). New discoveries continue to be made: a nontechnical account of a Mithraeum discovered in 1949 is given by I. A. Richmond in *Recent Archaeological Excavations in Britain*, ed. by R. L. S. Bruce-Mitford, ch. iv, with good plates (1956). The important Mithraeum from Doura-Europus was brought to the U.S. and reassembled in the Yale university art gallery in New Haven, Conn. (F. R. Wx.)

**MITO,** historic Japanese city and capital of Ibaraki prefecture in central Honshu. A commercial and railroad centre, it is about 60 mi. N.E. of Tokyo on the northern edge of the Tokyo plain. Between 1940 and 1960 its area increased from 13 sq.km. (5 sq.mi.) to 146 sq.km. (56.4 sq.mi.) and the population from 66,300 to 139,389. An ancient castle town, Mito became the seat of one of the three main branches of the Tokugawa family in 1606.
(C. A. Mr.)

**MITRE, BARTOLOMÉ** (1821–1906), was an Argentine statesman, soldier and author who contributed much to his nation's progress in the second half of the 19th century. Born in Buenos Aires on July 26, 1821, Mitre moved with his family to Uruguay in the 1830s. He entered military school and joined the liberal exiles from Argentina in their literary opposition to the dictator Juan Manuel de Rosas. Because of his liberalism, Mitre became an exile from Argentina. From Uruguay he traveled to Bolivia, Peru and Chile, where he studied, wrote, served in military campaigns and plotted against Rosas. When Rosas was finally defeated at Caseros (1852), Mitre played a prominent role as commander of Uruguayan artillery.

After the fall of Rosas, Argentina desperately needed constitutional government to unify the nation and develop the economy. Mitre believed that the port city and fertile agricultural province of Buenos Aires must lead the country. Therefore, he worked to split his province away from the new Argentine Confederation; as governor and commander of the provincial army he defeated the forces of the confederation at Pavón (1861). He then moved the national capital to Buenos Aires and was elected president of Argentina, serving from 1862 to 1868. An informed believer in the doctrines of European liberalism, Mitre created and strengthened instruments of civil administration, suppressed provincial *caudillos* and encouraged foreign immigration and investment. He also led the allied forces for a time during the Paraguayan War.

After his presidency Mitre was elected to the senate, where he long served. In 1874 he led an unsuccessful revolution, claiming that he had been defrauded of the presidency by the government in the elections of that year. In 1891, in another unfortunate venture into presidential politics, he became the candidate of the new middle class Unión Cívica party, only to withdraw in favour of the conservatives, thus assuring the continued political domination of the oligarchy.

Despite these events Mitre in the last years of his life came to hold a high position in Argentine hearts as a wise and honest elder statesman, a link to the turbulent past and a guide in the booming present. He died in Buenos Aires on Jan. 18, 1906.

His contributions to Argentine cultural development were also of first importance. He was founder and proprietor of the newspaper *La Nación* (1870). He wrote much poetry and many prose works and did considerable translating, including Dante's *Divine Comedy*. His major accomplishments were his historical studies. He wrote the multivolume works *Historia de Belgrano* and *Historia de San Martín*, and he was the founder of the Argentine Academy of History. (T. F. McG.)

**MITRE,** a liturgical headdress of the Western Church, generally proper to bishops. The word is derived through the Latin from the Greek *mitra*, "turban."

In the Roman Catholic Church its actual form is that of a sort

BY COURTESY OF MUSÉE GROENINGE, BRUGES. PHOTOGRAPH, ART REFERENCE BUREAU

DETAIL OF ST. DONATIAN WEARING MITRE AND BANDS FROM "MADONNA WITH CANON VAN DER PAELEN." PAINTED FOR THE CHURCH OF ST. DONATIAN IN BRUGES, BELG., BY JAN VAN EYCK, 1436. IN MUSÉE GROENINGE (MUSÉE COMMUNAL DES BEAUX-ARTS), BRUGES

of folding cap consisting of two halves which, when not worn, lie flat upon each other. These sides are stiffened and when the mitre is worn rise in front and behind like two horns pointed at the tips. From the lower rim of the mitre at the back hang two bands (*infulae*), terminating in fringes. Mitres are divided into three classes: (1) *mitra pretiosa* (precious mitre), decorated with jewels, gold plates, etc.; (2) *mitra auriphrygiata* (golden or orphreyed mitre), of white silk, sometimes embroidered with gold and silver thread or small pearls or of cloth of gold plain; (3) *mitra simplex* (simple mitre), of white silk damask, silk or linen, with the two falling bands behind terminating in red fringes. Mitres have been since the 12th century the distinctive headdress of bishops, but the right to wear them, as in the case of the other episcopal insignia, is granted by the popes to other dignitaries. Bishops alone (including of course the pope and his cardinals) are entitled to wear the *pretiosa* and *auriphrygiata;* others wear the *mitra simplex*.

The original form of the mitre was that of the early papal tiara (*q.v.*); *i.e.*, a somewhat high conical cap. The stages of its general development from this shape to the high double-horned modern mitre are clearly traceable though it is impossible exactly to distinguish them in point of date. The most characteristic modifications may be said to have taken place from the 11th to the middle of the 13th century. About 1100 the conical mitre begins to give place to a round one; a band of embroidery is next set over the top from back to front, which tends to bulge up the soft material on either side; and these bulges develop into points or horns. Mitres with horns on either side seem to have been worn until the end of the 12th century. The custom of setting horns over the front and back of the head instead of the sides, however, was already growing and with this the essential character of the mitre during the middle ages was established.

In most of the Reformed churches the use of mitres was abandoned with that of the other vestments. They have continued to be worn, however, by the bishops of the Scandinavian Lutheran churches. In the Church of England the liturgical use of the mitre was discontinued at the Reformation but was revived in the latter part of the 19th century and has come to be fairly widespread.

In the Orthodox Eastern Church the mitre is proper only to bishops. Its form differs entirely from that of the Latin Church. In general it rather resembles a closed crown, surmounted by a cross. In Russia the cross usually lies flat, only certain dignitaries having the right to have the cross upright. In the Armenian Church priests and archdeacons as well as bishops wear a mitre. In the Syrian Church only the patriarch wears a mitre, which resembles that of the Greeks. The *burnā* of the Chaldean Nestorians, on the other hand, worn by all bishops, is a sort of hood ornamented with a cross. Coptic priests and bishops wear the *ballin*, a long strip of stuff ornamented with crosses, etc., and wound turban-wise around the head. The patriarch of Alexandria has a helmetlike mitre, the origin of which is unknown, though it perhaps antedates the appearance of the *phrygium* at Rome. The Maronites and the Uniate churches have adopted the Roman mitre.

*See* also VESTMENTS, ECCLESIASTICAL.

**MITROPOULOS, DIMITRI** (1896–1960), Greek-U.S. symphony and opera conductor, was born in Athens, Feb. 18, 1896. After serving as assistant conductor of the Berlin State opera from 1921 to 1924, he was director of the Athens conserva-

tory until 1930, then appeared as guest conductor and pianist with leading European orchestras.

He went to the U.S. in 1936 as guest conductor of the Boston Symphony orchestra, and was director of the Minneapolis Symphony from 1937 to 1949. Rejecting the traditional social obligations of the position, he adhered to an austere routine. However, he won a devoted following. He became a U.S. citizen in 1946.

He served as musical director of the New York Philharmonic-Symphony society from 1951 to 1955. In 1954 he began a new career as a conductor of the Metropolitan Opera, and became the Metropolitan's principal conductor in 1958. He died Nov. 2, 1960, in Milan, Italy, following a heart attack sustained at an opera rehearsal at La Scala. (J. Av.)

**MITSCHER, MARC ANDREW** (1887–1947), U.S. naval officer, who with conspicuous success commanded the aircraft carrier force, the famous task force 58, in the Pacific during World War II. He was born in Hillsboro, Wis., Jan. 26, 1887, and graduated from the United States Naval academy in 1910. On June 2, 1916, he qualified as the 33rd U.S. naval aviator. Mitscher had an important share in the development of naval aviation and in the integration of aviation into the U.S. fleet. Early in World War II he commanded the aircraft carrier "Hornet" in the battle of Midway. As a rear admiral, he commanded all aircraft in the Solomon Islands during bitter fighting there in 1943. As a vice admiral he commanded the fast carriers from Jan. 6, 1944, leading this task force in air strikes on Truk, in the battle of the Philippine sea, the battle for Leyte gulf, and the captures of Iwo Jima and Okinawa.

Mitscher died on Feb. 3, 1947, while serving as commander in chief of the U.S. Atlantic fleet, having held the rank of admiral from Sept. 13, 1946. (J. B. Hs.)

**MITTAG-LEFFLER, MAGNUS GÖSTA** (1846–1927), Swedish mathematician who founded *Acta Mathematica*, was born at Stockholm on March 16, 1846. He studied at Uppsala and later became lecturer at the University of Uppsala (1872–77), professor at Helsingfors (1877–81) and finally professor at Stockholm, being rector of the university in 1886, 1891 and 1893. Mittag-Leffler founded the journal *Acta Mathematica* in 1883, set up an editorial staff from the four Scandinavian countries, gained the patronage of Oscar II of Sweden and acted as chief editor for 45 years.

Mittag-Leffler made a number of contributions to analysis. He worked on the general theory of functions and gave a proof of Cauchy's theorem. He also dealt with the problem of the analytic representation of a one-valued function a result of which was the well-known Mittag-Leffler theorem. A good deal of his researches laid the foundation of later work of the Swedish school of function theoretical studies. He died at Stockholm on July 7, 1927, leaving his estate and mathematical library to the Mittag-Leffler Mathematical institute at Djursholm near Stockholm. (O. Oe.)

**MITTELLAND CANAL** (Ems-Weser-Elbe-Kanal), a German waterway begun in 1905 and completed in the late 1930s. It runs from the Dortmund-Ems canal east of Rheine and eastward along the northern border of the Central Uplands, to the Elbe north of Magdeburg (a distance of about 290 mi.), linking there with the Havel canal eastward to Berlin. Side canals connect it with Osnabrück, Hanover, Salzgitter (the new iron and steel centre) and Hildesheim. Peine (iron and steel works), between Brunswick and Hanover, and Wolfsburg (Volkswagen plant) are both on the main canal, which carries barges of up to 1,000 tons. It is closed by ice for two to three weeks in winter. Locks connect it with the Weser and Elbe rivers. A large part of the traffic consists of coal and iron ores. *See* also Ems River; Weser; Elbe. (R. E. Dl.)

**MIVART, ST. GEORGE JACKSON** (1827–1900), English biologist, known for his studies of comparative vertebrate anatomy, was born on Nov. 30, 1827, in London. In 1851 he was called to the bar, but devoting himself to scientific studies, he was appointed lecturer at St. Mary's hospital medical school in 1862, and from 1874 to 1877 was professor of biology at the short-lived Catholic University college, London. In 1871 his essay *On the Genesis of Species* brought him into the controversy then raging round the theories of Darwin, and ultimately led to his estrangement from both Darwin and Huxley. Though admitting evolution in general, Mivart emphasized the distinction between organic and inorganic matter, minimized the importance of natural selection, and, especially in his *Nature and Thought* (1882) and *The Origin of Human Reason* (1889), denied the evolution of the human intellect.

Among the scientific works of Mivart are: *Lessons in Elementary Anatomy* (1873), *Man and Apes* (1873), *The Common Frog* (1874) and *The Cat: an Introduction to the Study of Backboned Animals* (1881). Some articles published in the journal *Nineteenth Century*, while he was professor of the philosophy of natural history at Louvain, advocated the claims of science even where they seemed to conflict with religion, and were placed on the *Index*. Other articles in Jan. 1900 confirmed his unorthodoxy and led to his excommunication by Cardinal Vaughan, with whom he had a curious correspondence about holding liberal opinions while remaining a Catholic. He died of diabetes shortly afterward, in London, on April 1, 1900.

See *Dictionary of National Biography*, vol. xxii (Supplement), pp. 1051–53.

**MIXE-ZOQUE** (Zoquean), a family of languages spoken by Mexican Indians, comprising Mixe (in eastern Oaxaca), Zoque (chiefly in northwestern Chiapas) and Popoluca (in east central Veracruz). The extinct Tapachulteca (of southern Chiapas) was apparently a dialect of Zoque. Genetic relationships among these languages have been clearly demonstrated; more distant affinities have been suggested as possible between Mixe-Zoque and the Mayan and Totonacan families. The 1950 census showed 46,101 Mixe and 18,023 Zoque; Popoluca was listed with the linguistically unrelated Popoloca of Puebla with a combined figure of 17,163.

*See* R. L. Beals *Ethnology of the Western Mixe* (1945); S. S. Hoogshagen and W. R. Merrifield, "Coatlán Mixe Kinship," *Southwestern Journal of Anthropology*, vol. 17 (1961). (W. L. Wo.)

**MIXTEC,** a Mexican Indian people occupying much of the western half of the state of Oaxaca as well as adjacent areas of the states of Guerrero and Puebla. They are culturally and politically important in the history of pre-Columbian Mesoamerica (*see* Middle America). Ranging from mountainous highlands to the Pacific coast, they did not achieve political unity—although four main centres of Mixtec power eventually emerged. On their eastern frontier the Mixtecs fought with the Zapotecs for the possession of border areas. Such centres as Monte Albán (now an archaeological site and tourist attraction outside Oaxaca city) presumably changed hands between Zapotecs and Mixtecs several times. On their western frontier the Mixtecs fought the Aztecs (*q.v.*), who finally subdued them not many years before the Spanish conquest. Surrounding peoples (such as the Mazatecs) were under Mixtec domination at certain times. The last independent Mixtec "kingdom" was conquered by the Spaniards over a quarter of a century after the conquest of Mexico City (1521).

The Mixtec language, along with Cuicatec and Trique, belongs to the Mixtecan language family. This family is, in turn, a branch of the Oto-Manguean stock of which Popolocan, Amuzgoan, Zapotecan, Otopamean, Chinantecan and Chiapanec-Mangucan are other branches. Like most Oto-Manguean languages and dialects, Mixtec has an involved system of musical pitches or tones that are lexically significant. In the 1960s about 155,000 people spoke Mixtec. *See* also Oaxaca.

Bibliography.—A. Dyk, *Mixteco Texts* (1959); R. E. Longacre, *Proto-Mixtecan* (1957); P. J. C. Dark, *Mixtec Ethnohistory* (1958). (R. E. Lo.)

**MIYAGI,** a prefecture (*ken*) in northeastern Japan, is the centre of communications and trade for the Tōhoku (northern Honshu) region. Area 2,813 sq.mi. Pop. (1960) 1,743,195. Miyagi was formed from sections of Rikuzen and Iwaki provinces which were part of Mutsu province before the restoration of 1868.

Its western mountains are part of the central range of Honshu. Its coastal range is broken by Matsushima bay, a beauty spot famous since Tokugawa times, and Sendai plain which contains Sendai, capital of the prefecture. Considerable effort has been made to develop sea trade by improving the harbours of Ishinomaki and Shiogama. (C. A. Ma.)

**MIYAZAKI,** a Japanese prefecture (*ken*) in southeastern Kyushu, was formed from the province of Hyūga after the restoration of 1868. Area 2,986 sq.mi. Pop. (1960) 1,134,590. Miyazaki is mountainous with a small coastal plain. A long growing season and the presence of the Japan current along its coast make two crops of rice possible in one year. The chief products are chemicals, wood pulp, bamboo goods and charcoal.

Miyazaki city (pop. [1960] 158,328), communications centre and capital of Miyazaki prefecture, is located on the largest agricultural plain of southeastern Kyushu. Miyazaki shrine commemorates the legend that the travels of the first emperor of Japan, Jimmu Tennō, started there (*see* SHINTŌ: *Primitive Shintō*).

(C. A. MR.)

**MIZO,** an autonomous district of Assam, India, was formerly known as the Lushai Hills district. It is the largest district of the state (area 8,134 sq.mi.) and is situated in the extreme south between Burma on the east and south and the Sarti hills of East Pakistan on the west. To the north lies the state of Manipur and the districts of Cachar and Tripura. Geologically the Lushai hills form a part of the Arakan arc which consists of compact parallel ridges with a north-south axis formed of Tertiary sandstone, limestone and shales. The ridges reach up to 7,000 ft. Pop. (1961) 266,063.

The hills are covered with thick evergreen forest containing valuable timbers and wild animals including elephant, rhinoceros, tiger, bear and deer. In the intermontane valleys *jhum* tillage (whereby tracts are cleared by burning and sown with mixed crops) and terrace cultivation are practised. Rice, maize (corn), cotton and vegetables are the main crops. Aijal and Lungleh are connected by a motor road with Silchar in Cachar district. With the independence of India in 1947 a road-building program was undertaken with the primary object of completing a north-south route from Silchar through Aijal to Paletwa in the Arakan district of Burma.

The area was originally inhabited by a small tribal group of Tibeto-Burman stock. Between 1750 and 1850 the Lushais migrated from the Chin hills and subjugated the aborigines, assimilating these similar tribes into their own society. The Lushais have a well-developed system of chieftainship and the whole district is divided into about 300 hereditary chieftainships. The Lushais are of the same kin as the Kukis, who are their neighbours but are fewer in number. More than 40% of the Lushais of this district are literate, the majority of these being Christians. The most powerful political organization of the Lushais is the Mizo union. It stands for the liquidation of the chieftainship and the establishment of a democratic land administration. At first Lushai Hills was divided into two administrative units, the southern unit administered by the government of Bengal and the northern by that of Assam. In 1898 the two parts were amalgamated into one administrative district and put under the government of Assam. A district council, as in other hill districts, administers Mizo under the Indian constitution. There are two subdivisions in the district: Aijal (pop. [1961] 14,257), the district headquarters, and Lungleh, the subdivisional headquarters. *See* also LUSHAI.

(M. BA.)

**MIZPAH** (MIZPEH) is the name of several places in the Old Testament: (1) the Hurrian land of Mizpah near Mt. Hermon (Josh. xi, 3, 8); (2) Ramath-mizpeh of Gilead (Josh. xiii, 26), probably the same as the Mizpah attacked by the Ammonites (Judg. x, 17) and the residence of Jephthah (Judg. xi, 11, 29, 34); (3) Mizpeh of Moab (I Sam. xxii, 3); (4) Mizpeh of southern Judah, probably near Lachish (Josh. xv, 38); (5) Mizpeh of Benjamin (Josh. xviii, 26), a point of assembly of the tribes (Judg. xx, 1–3, xxi, 1–8; I Sam. vii, 5–12, x, 17) and a holy place (Hos. v, 1).

The last is by far the most important. Asa of Judah fortified it against Israel (I Kings xv, 22), the border of Israel and Judah ran very near it. It was the residence of Gedaliah, appointed governor of Judah by the Babylonians after the fall of Jerusalem (II Kings xxv, 23–25; Jer. xl, 10, 15) and there Gedaliah and his companions were murdered by Ishmael (Jer. xli). Mizpah was occupied in the time of Nehemiah (Neh. iii, 7) and gave its name to the district (Neh. iii, 15) governed by the "ruler of Mizpah" (Neh. iii, 19). In the Maccabean period it was a place of assembly, the memory of its sanctuary still surviving (I Macc. iii, 46). Traditionally located at the hill of Nebi Samwil, about six miles northwest of Jerusalem, Mizpah is more probably identified with Tell en-Nasbeh, about eight miles north of Jerusalem. The site, excavated by W. F. Badè in 1932–35, disclosed massive fortifications from the 10th century B.C., in particular a well-preserved revetment, burial vaults and a Canaanite high place.

(J. L. MCK.)

**MIZRAIM** (Hebrew MISRAYIM) is the Hebrew name for Egypt. In the Authorized version of the Bible, at Gen. x, 6 and 13, "Mizraim" is given as the name of one of the sons of Ham ("Mesram" in the Douai version). The Revised Standard version uses "Egypt" everywhere.

**MJÖSA, LAKE,** in Oppland and Hedmark *fylker* (counties) and the largest lake in Norway, is situated to the south of the Gudbrandsdal (*q.v.*). It is about 62 mi. long and 1–10 mi. wide, covering an area of 141 sq.mi., and has a maximum depth of 245 fathoms; it contains the small island of Helgøy. The Lågen river (*q.v.*) empties into its northern end, and it is drained south by the Vorma into the Glomma (*q.v.*) river. Mjösa abounds in fish (trout, fresh-water herring) and is a popular boating area. The surroundings of the lake vary from open cultivated landscape to forested hills; Lillehammer, at the northern end of the lake, is a noted tourist centre. Hamar and Gjøvik on the eastern and western shores, respectively, are industrial and commercial towns.

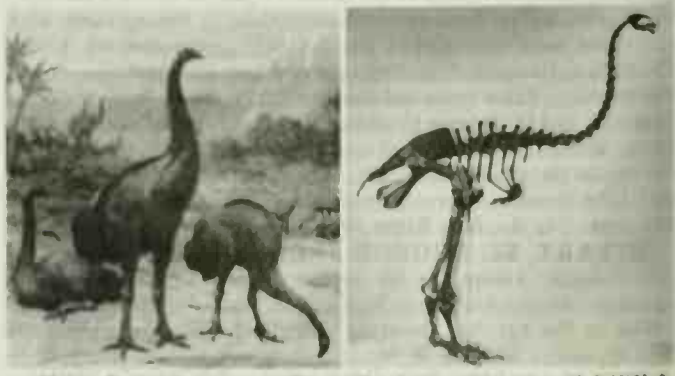
(L. H. HG.)

**M.K.S.** (GIORGI) **SYSTEM:** *see* PHYSICAL UNITS.

**MNEMONICS,** or *memoria technica*, the general name applied to devices for aiding the memory. The principle is to enable the mind to reproduce a relatively unfamiliar idea, and especially a series of dissociated ideas, by connecting it, or them, in some artificial whole, the parts of which are mutually suggestive. Among the most famous examples of metrical mnemonics are the "gender rhymes" of the Latin grammars, the hexameter lines (especially that beginning "Barbara Celarent") invented by logicians and the verse for remembering the number of days in the months ("Thirty days hath September, April, June and November"). *See* also MEMORY.

**MNESICLES,** the architect of the great Propylaea of the Athenian Acropolis, set up by Pericles about 437 B.C.; *see* PROPYLAEA. Mnesicles is also thought to have been the original architect of the Erechtheum (*q.v.*).

**MOA,** the Maori name of the extinct, flightless, ostrichlike birds comprising the New Zealand order Dinornithiformes (*see* BIRD). In the North Island the moas seem to have died out about 500–700 years ago, probably before the arrival of the Maoris. In the South Island moas of the genus *Emeus* lingered much longer, possibly in the unexplored interior even down to the



BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM (LEFT) FROM A MURAL BY CHARLES R. KNIGHT

MOA (DINORNIS ROBUSTUS), EXTINCT FLIGHTLESS BIRD. AT LEFT, RESTORATION DRAWING. AT RIGHT, SKELETAL CAST OF RECENTLY EXTINCT NEW ZEALAND MOA (EMEUS)

time when Capt. James Cook visited New Zealand (1769).

Numerous bones of the moa have been found in caves, swamps and kitchen middens, and some pieces of bodies with skin and feathers. The wings and shoulder girdle, except for a few vestiges in one species (*Anomalopteryx dromaeoides*), had entirely disappeared. There is no trace of a keel on the sternum. The hind limbs were very strong and ended in four toes. The bill was short and stout and the feathers had a large aftershaft. The moas varied from the 12-ft.-high *Dinornis robustus* to the size of a turkey (*Anomalopteryx parva*). Their affinities are with the kiwis. Moas are known only as far back as the Pliocene, and seem to have been herbivorous. *See* also KIWI.

**MOAB,** the name of an ancient people and occasionally of their country; *i.e.*, the highlands east of the Dead sea. Apart from the Moabite stone and some fragmentary inscriptions, no Moabite literature has survived. The main source of information about Moab is the Old Testament, supplemented by a few data from Assyrian and Egyptian documents and the results of modern archaeological research. The latter revealed a dense occupation of the plateau during the Bronze Age, from the 23rd to the 20th century B.C., with a highly developed agricultural civilization. This seems to have come to a sudden end and there follows a gap of about six centuries in the history of the country. Toward the end of the 14th century B.C. a new civilization appeared, that of the Moabites.

Nothing is known about the descent of this people. Representing Moab and Ammon as "sons" of Lot, the nephew of Abraham (Gen. xix, 30–38), Israel expressed its conviction that those two peoples belonged to the same ethnic group as itself. It also maintained the tradition that the Moabites were already settled and organized into a kingdom while the Israelites were still on their journey to the country God had destined for them (*cf.* Deut. ii, 29 with 9 and 19). From the fragmentary traditions about their route through Moabite territory as preserved in Numbers it may be gathered that, while the southern border of Moab was always the wide valley with precipitous sides now called Wadi al Hesa (probably the brook Zered of Num. xxi, 12), separating Moab from Edom, the northern frontier was fluctuating. It is said that the Amorite king Sihon threw the Moabites back southward behind the Arnon (Num. xxi, 26; *cf.* Judg. xi, 18, 22). Israel defeated Sihon and therefore could camp in the Jordan valley opposite Jericho, in the so-called steppes of Moab. The story of the Moabite king Balak who asked Balaam (*q.v.*) to curse Israel (Num. xxii–xxiv) seems to suggest a domination of Moab north of the Arnon, as does the narrative from the time of the judges about King Eglon, who even extended his power over the region of Jericho where he was murdered by Ehud (Judg. iii, 12–30). There is a mention of Saul's fighting against the Moabites (I Sam. xiv, 47), who granted asylum to the family of young David (I Sam. xxii, 3–4). There may be some connection between this fact and the tradition which gives the Moabite Ruth a place among David's ancestors (Ruth iv, 17–22; *cf.* I Chron. ii, 11–15). Later David fought a successful war against Moab and extracted a heavy tribute (II Sam. viii, 2). Solomon, as a sign of his authority, took Moabite princesses into his harem and built them a sanctuary for their national god, Chemosh, near Jerusalem (I Kings xi, 1, 7). It is probable that the Moabites took part in the movement of revolt which followed Solomon's death and that they again took possession of the territory north of the Arnon that they had lost since the time of David.

It was Omri, king of northern Israel (*c.* 884–*c.* 875 B.C.), who drove the Moabites again southward and conquered some of their cities, such as Ataroth, Kiryathaim, Baal-Peor and Medeba. This is known from the Moabite stone, a stele that the Moabite king Mesha erected some 40 years later in his important city of Dibon (Dhiban), just north of the Arnon. This black basalt stone, a little over one metre high, was discovered intact in 1868, but was subsequently broken by the population. It was taken to the Louvre in 1873, where it was mended and the inscription in the Moabite language restored, thanks to a cast made before it was broken. This text of 35 lines, graphically and linguistically very similar to contemporary Hebrew inscriptions, is the only written document of any length which survives from Moab and the only

ARCHIVES PHOTOGRAPHIQUES

STELE OF MESHA, THE MOABITE STONE, 9TH CENTURY B.C., IN THE LOUVRE

royal stele known from Israel's neighbours. Though some details are not entirely clear, it gives a valuable supplement to the six verses the Bible devotes to King Omri (I Kings xvi, 23–28). Mesha tells that Omri's victory took place during the reign of his father. He himself had still to pay the heavy tribute to Israel's king, "a hundred thousand lambs, and the wool of a hundred thousand rams," according to II Kings iii, 4. Mesha probably started his rebellion under Ahab, Omri's son, completing his action after the latter's death (II Kings i, 1). On his stele Mesha ascribes the Israelite domination over Moab to the anger of Chemosh. This god then roused Mesha:

> and Chemosh said to me "Go, take Nebo from Israel!" So I went by night and fought against it from the break of dawn until noon and I took it and slew them all, seven thousand men, boys, women, girls and maid-servants, for I had devoted them to destruction for Ashtar-Chemosh. And I took from there the [vessels] of Yahweh, dragging them before Chemosh. And the king of Israel had built Jahaz, and he dwelt there while he was fighting against me, but Chemosh drove him out before me . . . " (lines 14–18).

According to the narrative of II Kings iii, Ahab's son Jehoram tried to subjugate Moab, attacking it from the south with the help of Judah and Edom. This raid does not seem to have had a lasting success. During the reign of Jehoram's successor, Jehu, the Aramaeans are said to have got control over the whole of Transjordan up to the Arnon (II Kings x, 32–33). That was taken over from them by the strong Jeroboam II (II Kings xiv, 25; but the expression "as far as the Sea of the Arabah" is not clear).

From the Assyrian records it appears that King Salamanu of Moab paid tribute to Tiglath-pileser III in 732 B.C. Later Moab

joined the revolt against Assyria with Judah and Philistia, which was suppressed by Sargon II in 711 B.C. Ten years later, as Hezekiah of Judah tried to rebel, Moab remained loyal to Assyria and its King Kammusunabdi "brought sumptuous gifts" to Sennacherib. Subsequently both Esarhaddon and Ashurbanipal received tribute from the Moabite king Musuri ("the Egyptian"). During the reign of Ashurbanipal Moab helped to repulse the invasion of the Nabayati and nomads of Kedar. Later, Moab joined the coalition against Babylonia (Jer. xxvii, 3) and was condemned for its joy at the fall of Jerusalem (Zeph. ii, 8–10), though it harboured fugitive Jews (Jer. xl, 11). According to Josephus the Babylonians subdued Moab in 582 B.C. Nothing certain can be said about the following centuries, except that the territory probably suffered from nomadic invasions. It came finally under the domination of the Nabataeans. Moabites were excluded from the Jewish community (*cf.* Deut. xxiii, 3–6), where the name Moab became a typical denomination for the enemies of God (Isa. xxv, 10).

As the Moabite stone proves, Moab had reached a high state of civilization by the 9th century B.C. Its language differed only dialectically from Hebrew; its religion and culture were very closely akin to the Israelite. The relation of Chemosh, the national god, to his "children" (Num. xxi, 29) was that of Yahweh to Israel (Judg. xi, 24). Apart from the religious cult suggested in the name Mount Nebo, there were local cults of the Baal of Peor and the Baal of Meon; and Mesha's allusion to Ashtar-Chemosh, a compound deity, has been taken to point to a corresponding consort whose existence might naturally be expected upon other grounds (*see* ASTARTE). The fertility of Moab, the wealth of wine and grain and the temperate climate supplied conditions which directed the form of cult. Nature-worship, as in Israel, prevailed, and the rites of Shittim and Baal-Peor (Num. xxxi, 16; Ps. cvi, 28) cannot have differed materially from practices condemned by the Israelite prophets.

H. van Zyl, *The Moabites* (1960). For the Moabite stone *see* G. A. Cooke, *A Text-Book of North Semitic Inscriptions* (1903) and J. B. Pritchard (ed.), *Ancient Near Eastern Texts*, pp. 320–321 (1955). (L. H. GR.)

**MOAT,** a depression surrounding a castle, city wall or other fortification, usually, but not always, filled with water. The existence of a moat was a natural result of early methods of fortification by earthworks, for the ditch produced by the removal of earth to form a rampart made a valuable part of the defense system. When, in the middle ages, earthworks gave way to masonry walls, the moat was retained, and became even more valuable than before as it prevented moving towers or battering rams from being brought up to the ramparts until the moat had been filled. With the development of firearms the moat lost much of its importance, but was occasionally retained into the 18th century as an obstacle against infantry attacks. Dry moats or ditches as parts of modern earthworks, still occur spasmodically. *See also* CASTLE; FORTIFICATION.

For a thorough consideration of medieval moats, *see* E. Viollet-le-Duc, *Dictionnaire Raisonné*, articles "Architecture Militaire" and "Château."

**MOBILE,** a city of southwestern Alabama, U.S., at the head of Mobile bay on the Gulf of Mexico, a river port and the state's only seaport; the seat of Mobile county. Maritime industry is extensive, including five shipyards in Mobile and the immediate vicinity. Brookley air force base is a major logistic installation of the U.S. air force and is one of the chief employers of labour in Mobile. Pop. (1960) city 202,779; standard metropolitan statistical area (Mobile and Baldwin counties) 563,864. (For comparative population figures *see* table in ALABAMA: *Population*.)

**History.**—The Mobile area was explored by Spaniards under Alonso Alvarez de Piñeda (1519), Panfilo de Narvaez (1528, with Nuñez Cabeza de Vaca), Francisco Maldonado (1540), Guido de las Bazares (1558) and Tristán de Luna (1559). French colonists under Jean Baptiste le Moyne, Sieur de Bienville, established Mobile at its present site in 1711, the first permanent European settlement in Alabama; and Mobile was the capital of French Louisiana (1711–20). Its name is a French adaptation of the name of an Indian tribe in the area.

French rule was followed in 1763 by British rule. During the American Revolution, Spanish forces under Bernardo de Gálvez captured Mobile. The United States occupied the city in 1813 and clarified its title by the Florida purchase (1819). In antebellum times Mobile became one of the leading ports in the export of cotton, and the Mobile and Ohio railroad was of major commercial importance in supplementing the river system.

During the American Civil War, trade with the West Indies and Europe was kept up despite a Federal blockade begun in 1861. In 1864 Adm. David G. Farragut entered the channel, captured the Confederate ironclad ram "Tennessee," destroyed one gunboat and drove another aground; in the engagement he lost the Federal monitor "Tecumseh." Ft. Gaines, on Dauphin Island, surrendered on Aug. 7, 1864; Ft. Morgan, on Mobile point, on Aug. 23. In the spring of 1865 Gen. E. R. S. Canby laid siege to Ft. Blakely and Spanish Fort, on the east side of the bay. After 25 days the forts, and then the city, were evacuated, and the Federal forces entered the city on April 12, 1865. In 1879 the municipality went bankrupt and in 1887 Mobile was again chartered as a city.

Banana importing commenced in 1893, supplementing the old export trade in lumber and cotton. Foreign and coasting trade was especially stimulated by the opening of the Panama canal. The opening of the system of locks and dams on the Warrior-Tombigbee rivers in 1915 proved to be a major event in the history of Mobile, as did the development of the Gulf Intracoastal waterway and the Federal Barge lines and the construction of the Alabama state docks, commenced in 1923. Cochrane bridge across Mobile bay (extending 10½ mi.) was completed in 1927 and Bankhead tunnel under the Mobile river in 1941. Bridge and tunnel together added materially to the trade area of Mobile by improving access to Baldwin county, which has the largest area of all Alabama counties.

Controlling depth of the ship channel has been a vital factor in the commerce and history of the city. Originally the minimum depth was only 5½ ft. In 1839 the channel had a minimum depth of 10 ft. but by 1867 the controlling depth was only 7 ft. A 13-ft. channel was opened in 1876. By 1888 the depth was 17 ft. and by World War I the channel was 27 ft. After World War II the channel's minimum depth was 36 ft. and width 400 ft.

**Population Characteristics.**—The population of Mobile in 1960 was 69.5% native-born white, 0.4% foreign-born white and 30.1% nonwhite, almost all Negro. From 1820 through 1900 Mobile was the most populous city in Alabama, but since 1910 each census has shown Birmingham in first place. For a time during World War II Mobile was the fastest-growing city in the nation.

**Commerce and Industry.**—Manufacturing was less important than commerce during most of the history of Mobile, but this ceased to be true in the 20th century. Textiles and food industries have long been significant. During World War I shipbuilding and other manufactures received considerable impetus. This was even more marked during World War II, when 196 ships were built in Mobile yards. One shipyard pioneered in welded hull construction, a process which proved of world-wide significance. Among the varied industries of Mobile are the manufacture of paper, aluminum, transportation equipment, lumber, food, textiles, chemicals, iron and steel. Factors in the growth of manufactures include the availability of electricity, water and petroleum; an adequate labour supply; and excellent transportation facilities. The principal oil field in Alabama is that at Citronelle in Mobile county. Manufacturing establishments in the county number over 200. In 1956 the total income in Mobile county was $229,072,000, as compared with $55,743,000 in 1939. These statistics summarize much of the economic history of the area during and after World War II.

**Education.**—Mobile is the site of Spring Hill college, a Roman

Catholic coeducational college, established in 1830 and chartered in 1836. There is also an extension centre of the University of Alabama.

**Parks and Recreation.**—Mobile has a number of city parks, including Bienville square in the business section. Other points of interest in Mobile and the immediate vicinity include Bellingrath gardens, an estate a few miles south of the city, noted for its collection of azaleas and japonicas; a statue of Adm. Raphael Semmes, the Confederate naval hero; numerous antebellum homes and churches; the U.S. Marine hospital building; waterfront scenes including the oyster dock, the banana wharf and shipyards located on Pinto Island, Blakely Island and at Chickasaw; Fort Morgan at Mobile Point (a state park); Fort Gaines and other scenes on Dauphin Island, 23 mi. S. of Mobile; and the U.S. quarantine station on Sand Island. Meaher and Gulf state parks are also nearby.

**MOBILIZATION, ECONOMIC.** Economic mobilization is the vast and complex process by which all the productive resources of a nation are organized and directed in support of a major war effort. It is the transformation of the economic system into a supporting base for the armed forces of the nation. It is far more than the nation in arms in the traditional sense (*see* CONSCRIPTION; MOBILIZATION AND DEMOBILIZATION, MILITARY). It is the redirection of the entire productive effort of a nation in support of a maximum and sustained war effort. Considered within the context of military science it is logistics writ large. In the older meaning of the term, logistics (*q.v.*) related simply to the transport, quartering and supply of troops. It was usually limited to supply operations in the field, taking for granted not only the production but also the procurement of munitions, equipment and supplies. More recently the concept of logistics has expanded to the point where some authorities define it so comprehensively as to include the entire industrial and economic base of military operations.

Economic mobilization is essentially a 20th-century phenomenon, although anticipations of it may be found in earlier wars. The experience of the Confederacy in the U.S. Civil War, for example, represents a groping, incomplete and largely ineffective effort to mobilize the economy of the South in the struggle against the North with its far greater wealth and resources. The Confederacy was greatly inferior in manpower, in finances, in transportation and shipping facilities and, above all, in productive capacity for turning out the munitions, supplies and equipment required by the armed forces. In the effort to make the most of these limited resources, Confederate and state governments resorted to a variety of extraordinary measures, which eventually included some degree of control over manpower, materials, transportation, foreign trade and prices as well as numerous government-owned and government-managed manufacturing establishments. Jealousy and friction between state and central governments, the poverty of administrative resources in a region where the role of government had extended little beyond the maintenance of order and, most importantly, the understandable failure adequately to grasp the nature and requirements of the situation combined to defeat the efforts to mobilize and manage a war economy.

### 20th-CENTURY MILITARY REVOLUTION

Both as concept and as process, economic mobilization is an outgrowth of the radical changes in the character and magnitude of warfare that have taken place since 1900. In all ages war has affected and been influenced by the prevailing economic system. Armed forces must be raised, trained, equipped, supplied and paid. The costs of war must be met in one way or another. Part of the product of the economy must be diverted from peacetime uses to the destructive purposes of war. The extent of such diversion rests at bottom on the ability of the economic system to produce a surplus beyond the bedrock requirements of the civilian population and the economy itself and upon the ability of the government to capture this surplus by taxation, borrowing or requisitioning. Paradoxically, the usual effect of war has been to stimulate rather than depress the economy. Business improves, prices rise, production and employment increase and opportunities for profit making multiply. War periods in modern times have typically been periods of high production and relative prosperity, however unfortunate the consequences for particular segments of the economy, such as foreign trade, and however distorted the pattern of normal production and of business relationships. Yet with all this stimulation, disturbance and distortion, prior to the 20th century the capitalist economy of the western world continued to function during war substantially as in peacetime.

The reasons for this are clear. The scale and intensity of military operations in earlier wars were very limited, however prolonged and burdensome the conflict. Armies moved on foot and fought with hand weapons; engagements were infrequent and of brief duration; firepower was low; food and forage presented the major problems of supply. The demands of the military were correspondingly small in relation to the total output of the typically agricultural economy. Military requirements were added to those of the civilian population without any significant change in the organization and functioning of the economy as a whole. Under such conditions, military supplies were obtained largely by an intensification of normal procurement procedures, operating within the free market, although often greatly hampered by the widening gap between supply and demand, by multiplying shortages and by spiraling prices. Occasionally there would be resort to the more drastic methods of forced requisitions of supplies but such measures, except in enemy territory, were exceptional. There was no direct intervention by government in the functioning of the economy, as such, by the control of prices, wages, profits and rent, distribution of scarce materials through systems of priorities and allocations or rationing and the control of credit and investment.

All this was changed as the result of the impact upon warfare of the extraordinary technological and industrial developments culminating in the generation before 1914. Industrialization was the keynote of economic advance in all the great powers. Large-scale organization and mass production were the characteristic features of the new industry. Mechanization proceeded rapidly in all branches of economic life, stimulated by new sources of power such as electricity and the internal-combustion engine, new fuels such as petroleum and natural gas, new materials such as steel, rubber and aluminum. Combined with new methods of organization and direction, the new technology brought great increases in productive capacity and efficiency. Applied to the art of war, the new means of production made possible the equipment of large military forces with weapons hitherto available only in small quantities and introduced novel weapons and matériel that gave new dimensions to combat. The result was a new kind of warfare, based on the mechanization of combat and the industrialization of supply. The breech-loading rifle and metallic cartridge, the machine gun, the rapid-fire, breech-loading field gun and comparable weapons in the naval field, especially the submarine and the self-propelled torpedo, raised warfare to an unprecedented level of intensity. Military operations were further mechanized by the introduction of the airplane and the tank, both made possible by the internal-combustion engine. The railroad and steamship were supplemented for the first time by motor truck and the older methods of communication by motor vehicles and field telephones. The superior efficiency of the new industrial to the traditional agricultural economy made possible a greatly increased diversion of materials and manpower to the purposes of war.

### WORLD WAR I

The attempt of Germany in 1914 to force a quick decision was frustrated in the first battle of the Marne and the conflict soon settled down to a stalemate of trench warfare on fronts hundreds of miles long with the opposed forces numbered in the millions. The huge numbers engaged, the long sustained actions rising to

periodic climaxes in great offensives, and the high rates of fire of mechanized weapons resulted in enormous expenditure of ammunition and correspondingly heavy consumption of other supplies. The scale of the resulting supply problem far exceeded anything anticipated by any of the great powers. Not one of the belligerent nations had plans for any such contingency. Efforts to cope with the emergency produced a disorganization not only of antiquated military supply systems that soon verged on chaos but of the supporting economies as well. National production declined rather than rose. The armed services competed with each other in the market as also did allies, compounding the confusion. The traditional methods of producing and procuring munitions within the framework of the free market, price incentives, private enterprise and competitive bidding, proved hopelessly inadequate. The gap between skyrocketing military requirements and limited sources of supply could not possibly be bridged. Spiraling prices were more productive of inflation than of badly needed goods.

Faced with supply crises that became worse with each passing week, the belligerent governments reluctantly accepted the necessity of extraordinary action. In the absence of both experience and plans and handicapped by the deeply embedded doctrines of individualism and *laissez faire*, the necessary directive action and controls came slowly and only under the compelling pressure of successive crises. The overriding need was to channel scarce materials, goods, manpower and productive capacity where they were most needed to advance the war effort, reducing or cutting off the flow to less essential or nonessential uses. Beginning usually with controls over the distribution of critically short supplies of raw materials, governments gradually brought under their direct management or regulatory control transportation, food, fuels, manpower, foreign trade, prices, wages, credit and profits.

Price inflation was a major threat to the entire war effort. Spiraling prices interfered with getting desperately needed production by introducing elements of uncertainty, risk and speculation in business activities at all levels. Inflation favoured the speculator as against the producer, seriously affected fixed-income groups and lowered the take-home pay of workers and soldiers alike faster than adjustments could be made in wage and pay rates. Profit appeared to take precedence over patriotism; public indignation was aroused and national unity and morale undermined. Price stabilization was the key to the stability and productive efficiency of the economy.

The compelling need for munitions in ever-larger quantities focused attention upon the manufacturing industries producing them and upon the measures for channeling industry into military production. The task was twofold: the conversion of plants making civilian-type products to the production of the far more exacting specifications and very different articles of war matériel; and the large-scale expansion of production of all goods and services required to meet the tremendous needs of the military added to civilian requirements. Conversion and expansion alike were difficult, time consuming and costly in scarce labour and materials. The term "industrial mobilization" was shortly coined to describe this industry-centred process. (*See* MOBILIZATION, INDUSTRIAL.) Adapted from the familiar military phrase for assembling and readying conscript armies for action, the term was apposite, for, as it seemed to manufacturers and businessmen generally, the extraordinary measures adopted by government amounted to scarcely less than the militarization of industrial production. Actually, not only production but the entire economic system became quickly and deeply involved in the war effort. Since industrial production takes place within the economic framework of such institutions as money, credit, prices and wages, the market, risks and investment, the mobilization of the one inevitably entails the mobilization of the rest.

## COMPARISON OF PEACE AND WAR ECONOMIES

Broadly considered, economic mobilization is the process by which the normal economy of peacetime is transformed into the war economy. The distinctive character of the war economy can best be understood by noting the effects of this transformation upon certain basic institutions of the private enterprise economy which, prior to World War II at least, was the ruling economic system among the great powers. In the typical war economy, private property is kept but loses something of its privacy since the owner's freedom to use it is restricted in numerous ways. The pursuit of self-interest and profit continues as the driving force of the economy but it becomes subject to many restraints and restrictions, as, for example, the multiplying regulatory controls. Property is made to bear a greatly increased burden of taxation, some of which is avowedly aimed at the recapture of the excessive profits usually accompanying wartime prosperity.

In two major respects, however, the war economy differs significantly from that of peacetime in nations where private enterprise prevails. In peacetime the basic decisions in the economy, that is, the decisions as to what goods and services are provided, of what quality, in what amounts and at what prices sold and bought, are made by private individuals or private business organizations, whether as producers, consumers, investors, workers or middlemen. In a war economy, on the other hand, these basic decisions and many other closely related ones are made by government agencies and government officials. They determine what is and what is not to be produced, in what quantities and for whom, and in what order of priority. Government takes the driving seat in the war economy and directs the operation of the vast and complicated productive machine of the nation so as best to support the national military effort. Businessmen and business organizations, workers and consumers still make decisions in a great many matters but they do so within the framework and limits of policies established and high-level decisions made by government.

Secondly, because the normally automatic stabilization of the economic system through the mechanism of prices and the free market breaks down as a result of the wide and continuing divergence between supply and demand in wartime, the government must step in and provide artificially the stability (or equilibrium) which the economic system no longer affords. It is significant that prices, the controlling and directing mechanism in peacetime, become themselves a primary object of control in the economy mobilized for war.

## WORLD WAR II

Economic mobilization from 1914 to 1918 was simply a prelude to the vaster and more complex mobilization of resources set in motion by the outbreak in 1939 of World War II. Blitzkrieg as conducted by Germany in Poland, the Low Countries and France was carried out with a surprisingly small commitment of military forces and with no mobilization of resources in the proper sense of the term. The fall of France and the evacuation of Dunkirk marked the beginning of the full-scale military effort. Thereafter the mobilization of the economies of the belligerents proceeded at a pace directly proportioned to the gravity of their military situations.

Mobilization and management of the war economy in World War II were in fundamental respects very similar to the experience of World War I. The differences resulted in the main from the far greater scale and intensity and the somewhat longer duration of the second war. In contrast with the continental scale of the first war, the second was global in extent, with military operations carried on in two major and a number of lesser theatres. Total direct war costs rose tenfold and more above those of the first war against increases of national product and income that were far less. The more fully committed nations, especially Britain, Germany and the U.S.S.R., devoted close to half their national incomes to the prosecution of the war, and the United States was not far behind.

On the technical side, World War II marked advances beyond World War I almost as striking as those that separated World War I from the wars of the 19th century. A highly mobile warfare on land and sea and in the air employed weapons and matériel of rapidly accelerating complexity and cost. The scientific and technological resources of the great powers that had played but a minor role in the first war were in the second as systematically and fully mobilized as industry. The resulting achievements greatly increased military effectiveness but at a cost both in the

productive resources allocated to research and development and in the strain which producing the new devices placed upon the economy. Air warfare both figuratively and literally added a new dimension to warfare. Mass bombing of population and production centres carried the war directly to the source of the enemy's military strength and compelled the diversion of scarce resources to the work of repair, rehabilitation and civil defense.

With the benefit of World War I experience and with advances in the understanding of the economy and the arts of government and administration, the belligerents began the mobilization of resources in 1939–40 in a far better position than 25 years earlier. However fumbling and haphazard some of the early efforts toward mobilization, governments in World War II had a far clearer grasp of the nature and requirements of a planned and managed war economy. That mobilization of industry was only part of the larger task of mobilizing the economy for war was understood from the outset. In the democratic nations there was at first a reluctance on the part of both businessmen and the general public to face up to the demands of total war, but informed men in industry and government alike clearly envisaged the general character and problems if not the magnitude of the task ahead. The general extension of governmental activities in the interwar years, especially in response to the crisis of the great depression, had both increased the understanding of the economy and its management and enlarged greatly the administrative machinery and skills of government. Governments were thus far better equipped to deal with the war emergency.

While the mobilization tasks of World War II were fundamentally much the same as in the earlier war, the greater scale and intensity of the war placed a far greater load on the supporting economies. It was necessary to develop tighter, more elaborate and more highly refined systems of controls, adding tremendously to the administrative burdens of the central authorities. In respect to such vital materials as steel, copper and aluminum, a system of priorities—preferential paper claims on materials—proved quite inadequate. Priorities had to be largely replaced by systems of allocations in which specific quantities of each material were allocated to specific production programs and uses. Eventually, shortages of materials and goods tended to resolve themselves into shortages of labour. Such shortages had to be met by new and more stringent manpower controls.

Stabilization of prices presented unusually difficult problems caused by the wide and growing gap between the purchasing power of a labour force enjoying full employment, with high wages increased by overtime, and the greatly diminished quantity of consumer goods. Systems of direct controls over prices, including wages, profits and rents, were supplemented by a variety of measures for absorbing purchasing power, including taxation, forced loans and government savings bond campaigns. Great ingenuity was shown in devising fiscal measures for supporting stabilization and meeting the problems of war financing.

### "COLD WAR" ERA

In the years after 1945, continuing international tensions, kept high by local wars and the unrelieved pressure of the "cold war" between the western and Soviet blocs, resulted in a new and greater emphasis upon civil defense and upon measures of economic readiness. The latter included government stockpiling of scarce materials, the establishment of reserves of production facilities and equipment and the building up of productive capacity in essential industries to serve as a mobilization base. Some beginnings were made in the dispersion of industrial capacity and the establishment of underground facilities as means for reducing vulnerability to aerial attack in future wars.

All such planning and preparedness measures were overshadowed by the advent of nuclear weapons. The relation of economic strength to military potential entered a phase in which only those nations with the capability of producing and delivering nuclear weapons in numbers could hope to qualify as great powers. The two leading nuclear powers were presumed to have the capability of delivering in a single massive attack on enemy population and production centres thousands of miles distant scores and possibly hundreds of nuclear bombs with a destructive power reckoned in millions of tons of TNT equivalent per bomb. Attacks of this magnitude could cause casualties numbered in tens of millions, destroy a substantial segment of a nation's productive capacity and seriously disorganize its entire economy for many months. Full recovery of the economy would require years.

Such massive nuclear strikes and counterstrikes, whether by manned bombers or by missiles, might bring the active phase of the war to an end in a matter of weeks if not days. The outcome would depend primarily upon the state of mobilized readiness of the striking and defensive forces of the combatant powers. Under such conditions, economic mobilization could hardly get started before the war would be over, let alone contribute to its outcome, however indispensable it would prove in the massive and prolonged task of rehabilitation and recovery.

The concept of mobilized readiness in the 1960s envisaged not only substantial military forces in being, with primary emphasis upon the strategic air arm, but also a level of military production capable of continuously replacing obsolescent weapons and weapons systems with new and more effective ones, with the possibility of continuing a limited output of key military items in the wake of a nuclear strike. Increasing attention was given to the possibility that general nuclear war with its catastrophic destructiveness might be avoided by mutual forbearance if not mutual consent. If wars should be in fact limited, either in the weapons used, in the manner of their use or in the extent of national and territorial involvement, some degree and form of economic mobilization for war in the future was considered probable.

*See* R. Elberton Smith, *The Army and Economic Mobilization* (1958); W. K. Hancock and M. M. Gowing, *British War Economy* (1949).

(L. C. H.)

**MOBILIZATION, INDUSTRIAL.** Industrial mobilization is a term that has come to be applied to the transformation of a nation's industry from its normal peacetime activity to the production of the weapons and supplies needed to support a major military effort. It is distinguished from economic mobilization in being limited to industrial aspects and not including the whole economy of a nation (*see* MOBILIZATION, ECONOMIC). It embraces a multitude of actions: conversion of factories from the production of civilian goods; extension of existing plants and construction of new facilities; the reconditioning, building and installation of machine tools and other industrial equipment; curtailment of the output of nonessential products; imposition of priorities, allocations, rationing and conservation measures to assure the effective use of manpower, materials and production facilities; and the design of organizational means to marshal a nation's productive resources, direct them in the best interest of the total war effort and co-ordinate the activities of all agencies concerned.

The concept and practice of industrial mobilization emerged from the experience of World Wars I and II. This experience, however, does not necessarily set the pattern for future warfare. Since World War II a wide-ranging "cold war" of indeterminate duration, a high incidence of limited wars and the threat of engulfment of all civilization in thermonuclear war have introduced new conditions and new concepts of national security. To rely on past patterns of mobilization in these circumstances, some think, is to lean on a broken reed.

### THE EXPERIENCE OF WORLD WAR I

The history of efforts to mobilize resources for war is almost as old as war itself. Both ancient and modern times are replete with examples of far-ranging military campaigns with highly disciplined forces supported by well-organized logistics systems. Yet by and large, until comparatively recent years, military operations involved relatively small disruption of normal economic life. Wars had been more in the nature of limited duels rather than struggles to the death. Standing armies and navies were maintained, and they were augmented in wartime, but never to a degree approximating the utmost capacity of nations. Battles were fought without putting all into the balance, and support for the fighting forces was rarely drawn to the point of an all-embracing draft on na-

tional resources. Yet government control of resources for munitions production was not uncommon in earlier wars; in the American Civil War, for example, severe material and industrial deficiencies compelled the Confederacy to resort to mobilization measures that foreshadowed later developments.

World War I is generally recognized as having ushered in a revolution in the relation of war to the internal life of the major belligerents. That war was more than the clash of armed forces in combat. Its prosecution depended first upon the possession of resources—manpower, materials, productive plants and technological skill. Victory in modern war, Woodrow Wilson observed, will come not from mere numbers, mere enthusiasm, mere national spirit, but from "the scientific conduct of war, the scientific application of industrial forces." Bernard M. Baruch, the prime mover of American industrial mobilization in World War I, reflected the same thought in his outline of the purposes and functions of the War Industries board: "It is not enough to mobilize the Nation's military strength. There must be a mobilization of her full economic resources—industrial, agricultural, and financial. These must be organized, coordinated, and directed with the same strategy that governs the operations of the purely military arms of service."

Yet none of the major powers had anticipated a struggle in which the massed resources and facilities of whole populations would have to be pitted against each other. Without exception, preparations for the industrial support of their armed forces had been largely neglected. German army officers, steeped in the tradition of the Teutonic knights, believed that warfare was a matter of combat; and the German general staff showed little interest in industrial matters. Though fully imbued with the concept of a "nation in arms," France had not accepted its industrial implications. England was no better prepared. And the United States, despite its opportunity to observe for three years the events abroad, entered the war, as it had all other wars in its history, virtually unprepared.

The tremendous scale and intensity of military operations confronted all the belligerents with problems of munitions production and supply which could not be solved by the normal functioning of their economic systems. The mobilization of armed forces had to be paralleled by the mobilization of economic resources for their support. It became necessary to establish controls over raw materials, industrial facilities, finance, foreign trade and prices, and to exercise central direction of war production. Industrial mobilization was attended by confusion and waste effort, difficulties of supply, improvisation and reorganization of governmental machinery, and extension of controls to restore the disturbed balance of the economy.

Von Hindenburg, referring to the industrial effort of the United States, observed: "Her brilliant, if pitiless war industry had entered the service of patriotism and not failed it. Under the compulsion of military necessity a ruthless autocracy was at work and rightly, even in this land at the portals of which the Statue of Liberty flashes its blinding light across the seas. They understood war." The fact was, however, that the United States, no less than the other belligerents, found it necessary to improvise under the pressure of actual war conditions. Though United States troops helped to end the stalemate, at the time of the Armistice in Nov. 1918 its munitions had only just begun to flow on a large scale from the factories. It was fortunate, indeed, that the British and French allies were able to supply the American expeditionary force in 1918 with heavy guns, airplanes and other specialized military equipment.

## THE EXPERIENCE OF WORLD WAR II

The redirection of productive plants and resources for war purposes was particularly marked in World War II, with its heavier demands on the nations' economics to meet the requirements of global conflict. World War II was truly a war of supply. Marching men, spectacular sea and air battles, courage and determination, brilliant strategy—all played their noteworthy parts. But it was no coincidence that victory lay with the nations that mustered overwhelming superiority in matériel. Differences in strategic concepts, in economic potential for war, in the psychological makeup of peoples and in prewar economic systems had unique impacts on the course of industrial mobilization among the various belligerents. In many respects, however, their experiences were somewhat similar.

**Readiness for Mobilization.**—Despite the experience of World War I, few of the major belligerents were prepared at the outset of World War II. Within the German army there was from the first a determination to make up for the mistakes and the defeat of World War I. Secret arrangements with German industry were begun as early as 1923. Through a so-called "statistical society," a medium was established for close collaboration between the army and most of the large German industries. Up to 1933, however, little had been accomplished in the way of specific war preparations. With Hitler's advent to power in Jan. 1933, Germany embarked on actual preparations for war. But its rearmament was far less extensive than has generally been supposed. The ensuing years saw a conflict in Germany between demands for the armed forces and demands for continued improvement of the civilian standard of living. Reluctant to give up its social and economic aims, the Nazi regime never resolved the conflict. The success of blitz warfare in 1939 and 1940 demonstrated not the superior mobilization of Germany but rather the utter lack of readiness on the part of its victims.

France was acutely aware of the threat from Germany. It drew detailed plans for mobilizing the nation's manpower, for manning the Maginot line and for moving forces quickly into position along the northeastern frontier. But the crucial years of 1933 to 1939 saw little evidence of industrial preparation for rearmament. In May 1940 the French army had ammunition on hand adequate for only about four months of active warfare, and large-scale production was not expected until at least two years after the beginning of hostilities. Static planning, inadequate readiness measures and internal dissension left France an easy prey for German blitzkrieg.

Sensing the gathering storm, the British war office, in the mid-1930s, accelerated its preparations for mobilization. It conducted surveys of industry, began to correct deficiencies in the military establishment and drafted plans for various economic controls. Until the fall of France in the summer of 1940, however, "business nearly as usual" prevailed in Great Britain. The need for tight regulation was not accepted even for shipping, imports or raw materials; and raw-material control was hampered by the existence of stocks already distributed to users. It was not until the end of 1941 that the essential framework for the full mobilization of British industrial resources was worked out.

Between 1868 and 1940 Japan had spanned the transition from a medieval, feudal society to one of the great powers in the world. With their legend of divinely granted supremacy over all other inhabitants of the earth, the Japanese people, spiritually and psychologically, were well conditioned for war. Aggressive industrial development had taken place in Manchuria, northern China and northern Korea. Priority emphasis was given early to the stimulation of heavy industry. Japan's economic structure, concentrated in a few family groups (the *zaibatsu*), was fostered and dominated by the government. Strategic industries were endowed with subsidies, and imports and exports were controlled to conserve foreign exchange needed to purchase raw materials from abroad. By a subtle system of economic penetration, Japan tapped the far reaches of the world for the things it needed—abaca from the Philippines, vegetable oils from the islands of the South Pacific, iron and steel scrap from the United States and raw cotton from India, South Africa and Brazil. By 1937, at the time of the outbreak of the war with China, national-defense industries accounted for nearly 62% of all new capital investments in Japan. Legislation the following year provided for all-out government control of the national economy.

The Soviet Union's completely controlled economy had assumed a pattern in peacetime that was readily adaptable to war. Since the 1917 revolution the major industries of the country had been planned, constructed and controlled by the government. Out of the development of its planned economy the Soviet government had a number of main industrial centres: Leningrad and

Moscow; the Donets basin; the Caucasus; the Urals; the Kuznetsk basin beyond the Urals eastward; and the central Asiatic Uzbek-Kazakh area. There was in the U.S.S.R. a system of industrial research institutes, all working under the general direction of the academy of sciences, constantly experimenting with new processes and items, and passing information on to other plants in the same or related fields.

In the United States the military services, acting under a legislative mandate of 1920, undertook a comprehensive planning program in which they sought to profit by the lessons of World War I and avoid the recurrence of past mistakes in another emergency. From 1930 to 1939 there emerged four successive editions of an *Industrial Mobilization Plan* which provided an administrative blueprint for the control and direction, under civilian auspices, of the nation's resources in time of war. Paper plans were bolstered somewhat by specific readiness steps—surveys and allocations of manufacturing facilities for the production of anticipated needs; educational orders and production studies for training industry in the manufacture of problem items; arsenal rehabilitation; stockpile accumulations; and the establishment of reserves of special machinery and equipment. Except for the facility allocations, however, the concrete readiness measures came only at the very end of the planning period and were rather limited in scope and coverage. Though this prewar planning was in some ways beneficial, its influence on the actual events of the nation's rearmament was far less than had been anticipated.

**The Resource Base for Mobilization.**—Regardless of their forms of government, all countries came to realize the fundamental importance of a strong base in resources for success in modern warfare. Despite its early start and the unity and resoluteness of its people, Japan's efforts at industrial mobilization were a failure. It mobilized about as fully as the paucity of its resources would permit. Like Germany, Japan drew to some extent on the resources of areas that it occupied and pacified. But Japan underestimated its own needs. The dependence of its islands upon large imports of raw materials and food made Japan especially vulnerable to blockade by sea and by air. Its ultimate defeat was induced primarily by the economic paralysis produced by this blockade.

In the first two years of the war Hitler rejected "armament in depth" as the basis for preparedness. His whole strategy was based upon short, decisive actions on a single front at a time. The campaigns in Poland, Norway, France and the Balkans followed this concept; and for such operations "armament in width" sufficed. Each campaign involved the complete utilization of Germany's land and air might in a blitz attack upon a single opponent. In the interval between each new attack, troop units were reorganized and re-equipped. The necessary supplies for a short campaign were accumulated, but no large reserves were built up and little was done to expand the basic industries upon which quantity production of munitions depends.

With Hitler's forces bogged down before Moscow in Dec. 1941 and with his declaration of war upon the United States, the dreaded spectre of a prolonged, two-front war became a reality for Germany. It was only then that a full-scale effort was made to mobilize the German economy for war. The ensuing "rationalization" of the economy, led by Albert Speer's ministry of armaments and war production, brought a threefold increase in munitions output by the end of 1944. However praiseworthy, the effort came too late. By then Germany was reduced by military defeats to almost its prewar boundaries; and its economy, disrupted by Allied air assaults, was on the downgrade. The war was lost in 1944, even though Hitler refused to see his doom until the bitter end in the spring of 1945.

Unlike Germany, the United States mobilized in depth for prolonged warfare. Between 1939 and 1944 its gross national product rose by more than 50%, after allowance for price changes. The volume of manufacturing nearly tripled, and the output of raw materials increased by 60%. Approximately $15,000,000,000 of new plants and equipment were added to the manufacturing capacity of the country. Two-thirds of the cost of this expansion was borne by the federal treasury, and tax concessions through accelerated amortization under "certificates of necessity" indirectly paid for a good part of the balance. Synthetic-rubber and aviation-gasoline industries were built up virtually from scratch; and others—explosives, guns and ammunition, aircraft, shipbuilding, aluminum, magnesium, tanks and various chemicals—underwent dramatic expansion.

The extended and more intensive use of manpower in the war years contributed greatly to the achievement of this record. The labour force increased almost 20%—from 54,100,000 to 64,000,000. The average workweek increased from 37.7 to 43.2 hours in manufacturing, from 32.4 to 39.5 hours in construction and from 32.3 to 43.9 hours in mining. The withdrawal of over 10,000,000 men for the armed forces was offset by absorption of all but a few hundred thousand of the 9,000,000 who were unemployed in 1939, and by drawing into the labour force housewives, youths, retired persons and the physically handicapped. At the same time, productivity climbed sharply as volume increased, manufacturing methods improved and workers responded to appeals for the faster flow of munitions to the fighting fronts.

America's expanded production for war was greater than the munitions output of its allies, and it was considerably greater than that of its enemies. In the five-year period from July 1, 1940, through July 31, 1945, there was an outpouring of 86,330 tanks; 296,400 airplanes; 15,300,000 rifles, carbines and sidearms; 315,000 artillery weapons (including tank and aircraft weapons and mortars); 4,200,000 tons of artillery shells; more than 41,000,000,000 rounds of small arms ammunition; 64,500 landing craft; 6,500 other navy ships; 5,400 cargo ships and transports; and similarly staggering amounts of other materiel. It was this munitions production that was the decisive factor in the final outcome of the struggle.

Yet it must be recognized that the industrial mobilization of the U.S. also saw much improvisation and fumbling, reluctance to forsake business-as-usual and delays in establishing administrative machinery with the cohesive force and potency required. As in World War I, the United States was again fortunate in being afforded time in which to mobilize its resources for war. When Pearl Harbor brought the United States into the war, the country had seen at least 18 months of partial mobilization. That preparation enabled its armed forces to begin offensive operations on a limited scale nine months later. But it took still another 12 months before the United States was ready to launch sustained attacks upon the enemy. A much too important part of the task of building up to full war production took place long after the war started.

**Problems of Administration and Control.**—In World War II, as in World War I, the mobilization of industry could not be effected through voluntary efforts by business and labour organizations. It required government machinery to direct resources into the most essential effort. Quite generally new agencies were set up for the purpose—in Great Britain, a ministry of production; in Germany, a ministry of armaments and war production; in Japan, a ministry of munitions; in the United States, a war production board. There were decided similarities in the organizations of these agencies, in the tasks they faced and in their means of performance. All had problems—in designing and programming production objectives; in diverting productive resources into appropriate war channels; in enlarging the production base; in establishing adequate industrial statistics; in devising workable priorities and allocation systems for channeling scarce resources to competing claimants; in preventing imbalance within and between production programs; and in achieving the necessary integration of industrial controls with related aspects of economic mobilization.

Problems of civil-military relationships did not lend themselves to easy resolution. In Great Britain separate ministries of supply and aircraft production were established to procure materiel for the army and air force, but naval procurement remained the responsibility of the admiralty. The German armed forces retained their separate supply systems, though after 1942 the Speer ministry guided and co-ordinated their efforts and took direct responsibility for planning, scheduling and controlling their production.

The pattern of relationships in the United States was substantially like that in Germany. Co-ordination in the United States appeared to be more difficult, however, and there was more evidence of controversy between the war production board and the armed services on policy and procedural matters.

The severity with which controls were applied to the civilian economy depended on circumstances in each case. The invasion by Germany interrupted the Soviet Union's third five-year plan, brought heavy losses of resources and necessitated large evacuations of equipment and labour into the Urals and eastward. The strain on the Soviet economy caused the disappearance of many consumer goods from the market and brought severe consumer rationing. The drain on Japan's limited resources also was such as to permit the meeting of only the submarginal requirements of the populace. In Great Britain supply difficulties, coupled with the altered strategic situation upon Italy's entry into the war and the fall of France, brought complete control of industry and increasing checks on the output of consumer goods. Cut off early from the most important sources of various materials, especially oil and rubber, Germany undertook the production of substitutes and imposed rigid restrictions and economy in the use of scarce resources.

In the United States the economy demonstrated a degree of strength, resourcefulness and productivity far greater than many had dared to imagine. Its people, for the most part, were subjected to inconvenience rather than sacrifice. Following its entry into the war the United States stopped passenger-automobile production, reduced the output of other consumer durable goods, and imposed consumer rationing of tires, gasoline, meat, coffee, sugar and other products. The unprecedented increase in the productivity and total output of the United States economy, however, enabled it to carry the heavy burden of mobilization and still permit the enjoyment of a steadily rising level of expenditures for civilian consumption. Larger amounts of soft goods and services made up for the new automobiles, electric appliances and aluminum cooking utensils which had to be denied to the civilian economy. Indeed, at the peak of U.S. war production in 1944, when over 40% of the gross national product was directed to war needs, the level of aggregate consumption of civilian goods exceeded that of 1939.

## COLD-WAR READINESS

Events after World War II demanded of nations a stronger, more flexible and more pervasive type of preparedness than they had ever had before. The postwar era was marked by an intensification of the ideological antagonism between the free world and the communist bloc. It saw, too, the introduction of nuclear weapons of incredibly destructive power. The east-west conflict turned into a gigantic "cold-war" rivalry with the accent on political, economic and psychological warfare. As part of their strategy the Soviets fomented crisis situations and small "brush fire" wars in the hope of attaining their objectives without risking the mutual annihilation that would attend all-out nuclear warfare. To counter this threat, the western allies had to fashion new instruments of policy and to develop and maintain the ability to deter aggression, wage limited war, and plan for survival and recuperation in the event of a massive nuclear attack.

This situation blurred the lines previously drawn between the normal pursuits of peace and the abnormal demands of war. The cold war came to be viewed as a struggle in which the social, economic and political fabric of a nation might be put to the supreme test before, and even barring, the outbreak of actual armed conflict on a major scale. The key to survival in this struggle, in the eyes of responsible planners, lay in assuring the strength of a nation's domestic economy and in seeking to create and maintain in other nations, both friendly and neutralist, the economic climate that would best nourish its own ideological and long-range power objectives. It required measures to help allied and friendly nations to resist economic and political penetration by opponents and to make the maximum contribution to the collective security arrangements of the group. It called further for nonmilitary measures calculated to weaken the capacity of the opposing nation to provide economic support for its national policy (*see* ECONOMIC WARFARE).

United States rearmament following the outbreak of the Korean War in June 1950 reflected recognition of the importance of a strong and ever-growing economy in the cold-war setting. The fighting in Korea was not the signal for full mobilization and attendant heavy demands upon the nation's industrial and civilian strength. In the Korean conflict it was not clear at what point in the future, if at all, it would be necessary to drain that strength for total war. Under these circumstances the safest course seemed to be to embark on a partial or "creeping" mobilization. It involved the buildup of an economic base adequate for fighting the war in Korea, for dealing promptly with emergencies elsewhere in the world, especially Europe, and for getting off to a good start on total mobilization if that should become necessary. The combination of defense preparations with continued growth of the underlying civilian economy was deemed necessary not only for purely economic reasons but also because of the psychological strain involved in carrying a military burden in a democracy without the pressure of an all-out war.

Under this mobilization strategy, a substantial buildup of fighting capability was accomplished for the long pull; and economic controls were so tailored and applied as to minimize the disruption of the civilian economy. Government aids through accelerated tax amortization, loans, subsidies and research and purchase contracts brought a large growth of industrial capacity throughout the economy, from basic material extraction through intermediate products and to assembly plants for the production of finished military equipment. A national stockpile of critical materials, an increase in active forces, sharpened manpower skills, and additional experience in organizing resources and government machinery for defense were still other means whereby the base for war mobilization was strengthened.

Yet there was some feeling that too much of the rearmament effort during and after the Korean War had been keyed to the least likely type of future warfare—a general war patterned after World War II. A large number of industrial facilities were in operation or on standby for quick conversion to war production. There were large government inventories of materials, machine tools and related metalworking equipment. Under an "M-day pool order program" the facilities of toolbuilders could be immediately put into production without awaiting orders from defense contractors. These readiness measures, along with plans for the organization and control of the economy, would help the nation to move more quickly into a World War II-type of mobilization.

There may be situations, however, where this "mobilization base" does not ensure readiness to deal effectively with the conditions of limited war. After the end of the Korean War, military planners directed their attention more and more toward the need for readiness to prevent or promptly scotch brush fires before they fanned into major nuclear conflagrations. The key to success in this type of operation, as was demonstrated in the middle-east crisis in the summer of 1958, does not lie in a base of planned suppliers, machine tools, and stockpiles of strategic and critical materials. It lies rather in forces-in-being; in trained reserves ready for immediate action; in supplies earmarked and ready for shipment; in the preshipment and strategic stocking of heavy equipment; in adequate airlift for high-priority combat, command and supporting elements; and in the speedy water transportation of the follow-up echelons to ensure the full realization of the fighting capabilities of the forces.

Nor is the mobilization base entirely adequate to the needs of a war of survival. Even as the nation bolsters its ability to cope with limited military actions, the possibilities of an all-out nuclear exchange cannot be ignored. Massive enemy attacks would leave millions of people killed or maimed, and the greater part of the nation's industrial potential would be knocked out or paralyzed. Experience contributes little to an understanding of the problems that would be encountered in this type of situation. To ease the impact on peoples and resources, the United States considered certain measures and, to some extent, actually put them into effect —strategic location of industry; protective construction; ar-

rangements for the continuity of governmental operations; provision of shelters in new and existing structures; improved warning, damage-assessment and communications systems; and the stockpiling of food, medicine and other survival supplies and equipment. Nonetheless, the ramifications of the problems of survival and recuperation have been so vast, so complex, so appalling and so demanding in sacrifice as to make inevitable a sense of frustration and futility in past efforts to cope with them. The U.S.S.R. appears to have started earlier and gone further with civil defense, postattack and recovery plans as a component of overall Soviet strength and readiness for war.

**MOBILIZATION AND DEMOBILIZATION, MILITARY.** In a military sense, mobilization is the assembling and organizing of the armed forces of a nation for active military service in time of war or other national emergency. In its full scope, mobilization includes the organization of all resources of a nation for active military service or for support of the military effort. Demobilization is the reverse of this process—the dismantling of the war organization and return to peacetime activities.

**Mobilization.**—The technological advances of the 20th century, particularly since the advent of the atomic age, have vastly increased the complexities of mobilization planning and mobilization implementation. The ratio of a nation's forces in being, which provide for defense during the mobilization period, to that nation's full war potential has always varied, and has depended on such factors as foreign policy, world tensions, strength and situation of allies and estimates of the time required to implement mobilization. Because of the tremendous power of nuclear weapons, and the speed with which they can be delivered to their targets, it is conceivable that a nation's war potential could be destroyed before mobilization could be started. This situation has increased the need for adequately prepared forces in being—*i.e.*, the standing army, navy and air force—which might be the only means available to continue the defense and launch a counterattack.

Mobilization planners must consider the following contingencies: (1) all-out nuclear war; (2) conventional war (without nuclear weapons); and (3) limited war (limited either in geographic area, strategic aims or by the types of weapons employed). The requirement for maintaining military forces in being at high levels as a deterrent to nuclear war and as a fighting force in the event of a massive nuclear attack has not altered the requirement for the maintenance of detailed, thoroughly co-ordinated mobilization plans to provide for both conventional and limited wars and for a nuclear war that may reach a point of stalemate through failure of either side to win a decision in the first few hours. Any war that continues longer than a few hours thus requires the implementation of mobilization plans.

Military mobilization, for any kind of war, includes the procurement and training of manpower for military purposes; the selection of areas and the construction of facilities for training and other military purposes; and the procurement and issuance of arms, ammunition, uniforms, equipment, vehicles and stores. The procurement of military manpower is in itself a complex task that includes the calling up of reserves; the induction of large numbers of raw recruits; the allocation of manpower to the army, navy and air force and, within these major components, to the respective arms, services and other subdivisions.

The procurement of military manpower during mobilization must be correlated with the procurement of the arms and equipment necessary for training and for combat, and must be synchronized with timetables for training and strategic deployment. Mobilization, to be effective, must not only be well organized but must have "everything in step." The detailed schedules showing size, type and composition of military units to be organized during mobilization are sometimes referred to as the troop basis.

The ramifications of all phases of mobilization and the necessity for organization, synchronization and speed have made it necessary for nations to prepare detailed, comprehensive mobilization plans and to keep them constantly under study and revision. Such plans may embody drafts of stand-by legislation for enactment when necessary.

**Demobilization.**—Just as a faulty, ineffective mobilization may result in a nation's military defeat, so a poor demobilization may result in the loss of objectives obtained by victory on the battlefield. All the military and economic factors that make mobilization so complex are also involved in demobilization, and for many reasons the problems may be even more difficult. Public opinion, which usually supports mobilization as a necessary means for winning a war, may well clamour only for speed in demobilization, even though such speed may jeopardize "winning the peace." Allies who have had unanimity of purpose and objective during mobilization and war may differ in their objectives following the war. The transportation facilities that deployed military manpower during mobilization and war may not be adequate to redeploy that manpower as rapidly as public opinion demands.

The main military tasks during demobilization are the following: (1) Manpower no longer needed in the armed services must be brought home and separated from the service. (2) Surplus war materiel must be disposed of and materiel required for reserve purposes must be properly stored to prevent its deterioration. (3) Requirements for military materiel for peace must be determined. (4) Missions of the armed services must be redefined to include, if applicable, occupation military government and rehabilitation of defeated countries. These factors, together with the economic factors of demobilization, are all related, but each one contains within itself complex problems that require careful advance planning. *See* also ARMY; CONSCRIPTION; MILITIA; MOBILIZATION, ECONOMIC; MOBILIZATION, INDUSTRIAL.

**MÖBIUS, AUGUST FERDINAND** (1790–1868), an outstanding German theoretical astronomer and mathematician, was born at Schulpforta, Prussia, on Nov. 17, 1790, and studied at Leipzig, Göttingen and Halle. In 1815 he became professor of astronomy at Leipzig, being chosen director of the university observatory, which was erected (1818–21) under his superintendence. He died in Leipzig on Sept. 26, 1868. *De computandis occultationibus fixarum per planetas* (1815) established his reputation as a theoretical astronomer. *Die Hauptsätze der Astronomie* (1836)

and *Die Elemente der Mechanik des Himmels* (1843) may be noted among his other purely astronomical publications. His labours in pure mathematics appear for the most part in *Crelle's Journal* from 1828 to 1858. These papers are chiefly geometrical, many of them being developments and applications of the methods laid down in his great work *Der barycentrische Calkul* (1827), which introduces homogeneous co-ordinates into analytical geometry. This treatise also deals with geometrical transformations, in particular projective transformations (collineations), and discusses the configuration known as the Möbius net, which later played an essential part in the systematic development of projective geometry. In the *Lehrbuch der Statik* (1837) Möbius gives a geometrical treatment of statics, leading to the null system of points and planes and thence to the study of systems of lines in space. Möbius was also a pioneer in the field of topology; in a memoir presented to the French Academy and discovered only after his death, he discusses the properties of one-sided surfaces, including the now celebrated Möbius strip. His *Gesammelten Werke* (4 vol.) were published in 1885–87.

His son THEODOR, an authority on Scandinavian letters, was born at Leipzig on June 22, 1821. His *Catalogus librorum islandicorum et Norwegicorum aetatis mediae* (1856) and *Verzeichnis der auf dem Gebiet der altnordischen Sprache und Literatur 1855 bis 1879 erschienenen Schriften* (1880) as keys to Scandinavian bibliography and his *Edda-Ausgabe* as a textbook are perhaps the most valuable to students. He died in Leipzig on April 25, 1890.

**MOÇÂMEDES** (MOSSÂMEDES), an Atlantic port of Angola, capital of the district of the same name, 200 mi. S.S.W. of Benguela. Pop. (1960) 7,963. Many of the town's inhabitants are fishermen from southern Portugal. It is the terminus of a railway, and has an airfield.

MOÇÂMEDES DISTRICT is made up of three *concelhos* (municipalities): Moçâmedes, Porto Alexandre and Bibala. Area 13,259 sq.mi. Pop. (1960) 43,419, of whom 6,905 were Europeans. The district lies on a coastal desert strip that extends from the Kunene (Cunene) river to the vicinity of Benguela. Its people live largely on fishing, though certain areas (mainly the Bero valley) produce fruits and vegetables. Many factories prepare fish meal and oil, fish preserves and dried fish. The most important fishing centres, other than Moçâmedes town, are Porto Alexandre, Baia dos Tigres and Lucira. The region is suitable for raising karakul sheep, and the Portuguese government has installed an experimental station to give technical assistance to sheep raisers.

**MOCATTA, FREDERICK DAVID** (1828–1905), English Jewish philanthropist and historian, was born in London on Jan. 15, 1828, a member of a distinguished financial family. His grandfather, Abraham Lumbrozo-Mocatta, had founded in 1790 the firm of Mocatta and Goldsmid (*see* also GOLDSMID), of which Frederick Mocatta was a member until his retirement in 1874 to devote himself to works of public and private benevolence.

He first began to give his attention to the better housing of the working classes and the administration of charity in such a manner as not to demoralize the poor. He supported almost every hospital in London, and did much to promote education, especially that of the Jewish poor. Mocatta encouraged Jewish literature and research, and in addition was a patron of learning and himself an author. The chief of his historical works was *The Jews of Spain and Portugal and the Inquisition* (1877). On the occasion of his 70th birthday, he was presented with a testimonial from more than 200 philanthropic and literary institutions.

Mocatta died on Jan. 16, 1905, bequeathing his fine library and art collection to the University college of London, in the library of which they are now housed.

**MOCCASIN,** a one-piece shoe made of deerskin or other soft leather, the sole is soft and flexible and the upper part is often adorned with embroidery, beading or other ornament. It was from earliest times the footwear of the North American Indian tribes and was also worn by hunters, traders and settlers. In modern times it has become a popular sport and casual shoe.

**MOCCASIN,** common name for certain poisonous, semi-aquatic snakes, genus *Agkistrodon*, found in North and Central America, especially the water moccasin or cottonmouth (*Agkistrodon piscivorus*). It belongs to the pit vipers, family Crotalidae, which includes also rattlesnakes, copperheads (*q.v.*) or highland moccasins, and many venomous serpents of Asia and one of southeastern Europe. Unfortunately, the term has been used also for various nonpoisonous water snakes, *Natrix*, because of their resemblance to the venomous cottonmouth. The harmless water snake, though it bites as readily as does the cottonmouth, has short solid teeth and no venom. The cottonmouth, on the other hand, has fangs and a powerful venom. Its bite, especially that of a large adult, is usually immediately followed by a sharp, stinging pain at the site of puncture. Antivenins are available and recovery from the bite, if prompt first aid and early medical attention are given, is almost assured.

Cottonmouths, divided into eastern and western subspecies, *A. p. piscivorus* (eastern and southeastern lowlands) and *A. p. leucostoma* (southern central states), are so called because of the cotton-white interior of the mouth. Their habit of threatening an intruder with open mouth, an uncommon reaction among venomous snakes, is a distinguishing characteristic of the cottonmouths. They are found in marshes and along or in streams or ponds where their preferred prey of frogs and fishes abound. Although some individuals exceed 5 ft., adults are more often 3 to 3½ ft. The pattern is dull and inconspicuous, consisting of dark-brown bars or blotches on a somewhat lighter background; in some cases, however, adults may be almost a uniform blackish. The females give birth to five to ten young in late summer. In captivity cottonmouths have lived as long as 18 years. A relative, the Mexican moccasin or *cantil* (*Agkistrodon bilineatus*), replaces *A. p. leucostoma* south of the Rio Grande. It is a more brightly coloured form that inhabits both coasts of Mexico and parts of Central America.

*See* SNAKE; VENOM. (L. M. KR.)

**MOCENIGO,** one of the oldest Venetian noble families, which provided the republic with many statesmen and soldiers and with seven doges. The first doge was TOMMASO (1343–1423), who had commanded the crusading fleet to Nicopolis (Nikopol) in 1396. He was elected in 1414, and it was during his reign that Venice's dominion was extended into the Trentino, Friuli and Dalmatia. But Tommaso's policy was peace, not aggression, and he is best remembered for the long deathbed address in which he describes, with great precision, the flourishing state of Venice and admonishes his fellow citizens to avoid warlike adventures in Italy. Tommaso also had the ducal palace rebuilt. His nephew PIETRO (1406–76) was one of the greatest Venetian admirals; he reorganized the Venetian fleet after the defeat of Negroponte (1470) and conducted successful reprisals against the Turks, taking Smyrna in 1472 and raising the siege of Scutari (Shkodër) in Albania. He was triumphantly elected doge in 1474 and, though the war continued, he tried to negotiate peace. A peace was reached, at the cost of losing Scutari, during the reign of Pietro's brother GIOVANNI (1408–85), who became doge in 1478. During the same reign was fought the War of Ferrara, in which Venice acquired Rovigo and the Polesine.

The next outstanding Mocenigo was Giovanni's grandson ANDREA (1473–1542), senator and scholar, who composed a verse history of the Turkish war of 1500 and a prose history of the League of Cambrai (printed 1525).

Andrea's nephew ALVISE I (1507–77) was doge from 1570; his reign was dominated by the war of Cyprus, in which Venice lost Nicosia and Famagusta to the Turks. A great-grandson of his brother Niccolò was doge as ALVISE II from 1700 to 1709. ALVISE III SEBASTIANO, fourth in descent from Alvise I's brother Giovanni, was doge from 1722 to 1732. Finally the reign of his dis-

tant cousin ALVISE IV (1763–78), fifth in descent from Niccolò, was notable for an enlightened commercial policy and a series of measures in restraint of clerical wealth and privilege which provoked a conflict with Pope Clement XIII.

**MOCHA STONE** (Moss Agate), a grayish to milky white variety of chalcedony (cryptocrystalline quartz) containing opaque, dark-coloured inclusions whose branching forms resemble ferns, moss or other vegetable matter. The included materials, mainly manganese and iron oxides, are of inorganic origin. Most mocha stones are found as fragments weathered from volcanic rocks. Long used for ornamental purposes, they are obtained chiefly from India, Brazil, Uruguay, the U.S.S.R., central Europe and the western United States. The best stones are cut in flat or rounded form, and some are dyed to improve their colour.

*See* also AGATE. (R. H. J.)

**MOCKINGBIRD,** a popular name of superb songbirds and mimics belonging to the American family Mimidae. The approximately 10 species of *Mimus*, ranging from southern Canada to Patagonia, are all similar in form—like slender, long-tailed robins—and in colour—like shrikes without the black facial mask. Popular in song and story, mockingbirds are chiefly beneficial, feeding mostly on insects but taking some berries in summer and autumn.

The common mockingbird of North America (*M. polyglottos*) is most abundant in the southern U.S.; the eastern subspecies appears to be a better mimic than the western. About 10 in. long, the common mockingbird is grayish above and dull white below, with white wing and tail patches conspicuous in flight. The nest, a bulky open cup of grass, twigs and rootlets carelessly arranged in a bush or dense tree, may hold three to six pale blue-green eggs, spotted with brown. Both parents prepare the nest and show great courage in defense of their home against such enemies as snakes, which eat both eggs and young.

Mockingbirds have a very pleasant and delightfully varied song of their own, and are capable of miming man-made sounds. In distinguishing the singing of the common Mimidae, the mockingbird repeats each phrase several times in succession before taking up another air; the thrasher (*q.v.*) usually repeats once; and the catbird (*q.v.*) does not repeat.

In parts of South America mockingbirds are prized as cage birds. Some species have been introduced into Hawaii. The long isolated

MOCKINGBIRD (MIMUS POLYGLOTTOS)

Galapagos mockingbirds, which have longer legs and longer bills than the mainland species, have been given generic rank as *Nesomimus*. *See* also SONGBIRD.

**MOCK ORANGE,** the name given to species of *Philadelphus*, especially to those with highly fragrant flowers, and also to the Missouri gourd or calabazilla (*Cucurbita foetidissima*) of the southwestern U.S. *See* CUCURBITACEAE; PHILADELPHUS.

**MODELS AND MODELMAKING.** The value of the model in various professions and industries, as well as its interest as a hobby, lies in its unique power to communicate the essential visual aspects of something planned or already existing. Thus since early times men have made models, at scales ranging from miniature to full size, as the most direct approach to exploring the special relationships of new constructions and of demonstrating the three-dimensional qualities of known ones. The Egyptians used realistic models of chattels in tombs to serve the deceased in the next world; in China similar tomb models became schematized into paper cutouts. Witches used models incorporating some fragment of the original in magic rites to effect good or evil. Renaissance artists used models to study the lighting and composition of elaborate groupings. Models of clothing and of architecture have been used from the 16th century on. Today modelmaking is a highly developed profession in the service of education, architecture, industry, the armed forces and other fields, as well as a hobby.

As an educational aid, the model has no peer in its ability to give the student an immediate grasp of certain kinds of material. The actions of opposing forces in the battle of Waterloo, the operation of moving parts in a reciprocating engine, the anatomical functions of the kidney system are examples of the myriad subjects which lend themselves to the medium of the model.

Science museums and exhibitions incorporate models into the presentation of various kinds of material. In natural history exhibits, for example, the habitat of fauna and flora can be recreated for thorough ecological study of environment by the observer. The methods of reproducing full-size landscape vignettes have been developed to a high degree of perfection. Material of vegetable nature is collected, from which molds and casts are made of plastic or other material with absolute fidelity. In these "habitat groups" the three-dimensional foreground is made to merge imperceptibly into a painted two-dimensional background.

In contrast to these models where complete faithfulness in all details is essential, schematic models may be desirable in certain instances where a principle is to be explained or a certain aspect is to be emphasized. For clarity in communicating an idea it is sometimes necessary to distort nature, select some of its elements and omit others and create new forms and colours. The initial stages in the design of exhibits are worked out by rough models for study purposes.

The materials and techniques employed in making scale models are unlimited. The success of the illusion depends to a great extent on the choice of material, according to the ability of its texture to suggest structures of a different size—for example, certain kinds of moss give a convincing suggestion of trees in foliage at a scale of 1:16. This is very useful for architects in rendering landscape for buildings that are being planned. The use of material designed for one purpose to convey the impression of another kind of material, seen at a different scale, is basic to modelmaking. It is part of the fascination for the one who makes the model (as well as a satisfactory illusion for the viewer) to discover a means of suggesting, for example, the cloud of insecticide being sprayed by an airplane.

Problems of architectural design can best be studied by means of models, since the element of three-dimensional space is vital in this field. The scope of the study may range from an entire city area to the interior of a single room; it may emphasize the outdoor space between buildings on a site, the flow of space from one room to another in one building or the colour scheme of an interior. Scale can be made immediately apparent by the use of human figures proportional to the project under consideration. The model can also be photographed and the illusion of full scale approximated by careful adjustment of lighting and background.

The plan for the redevelopment of downtown Philadelphia was implemented by a model showing the area as it then existed; the part representing the section of the area under consideration could be turned over mechanically to reveal the projected improvement of that area. A very successful use of models for publicity purposes was seen in the "Highway of Tomorrow" exhibit of the General Motors corporation at the New York World's fair in 1939–40. In this exhibit the visitor was carried on a belt of moving chairs through a landscape in which the highway of 1939 gradually evolved into the highway of the future.

Nearly all industries use models varying in scale and purpose,

the greatest value, however, derives from experimentation. Scale models of entire proposed factories are made to check location of machines, stock rooms and other features and to determine efficiency of production-line assembly. The early stages of the design of nearly all manufactured products require study of small-scale models. Full-size models are then made to refine the details of the finished design and to determine tooling requirements in the case of automobiles, refrigerators or other mass-produced items. Models of various scales are used in the fields of shipbuilding and aerodynamics. In the latter, the models are tested in wind tunnels at speeds greatly exceeding that of sound. This testing ensures perfection of design without risking human life and expensive equipment.

Industry has its own educational programs and uses cutaway or clear plastic models to demonstrate working relationships of machine parts and problems of assembly or disassembly. It is here that oversize models most often are used to demonstrate the workings of small mechanical parts, although magnified models are used also as display devices by watchmakers or other manufacturers of tiny, intricate artifacts.

Some unusual models have resulted from the study of water flow. One of the largest of these is a complete working model of the Mississippi river basin which is used by the U.S. government for demonstrations and experiments in flood and channel control. Another interesting model which served a valuable purpose in this field was a scaled-down section of the Suez canal, the function of which was to determine precisely what pressures the banks must withstand. Installed in a hydraulic laboratory in Grenoble, France, it was 210 ft. long and 20½ ft. wide. In it a self-propelled model of the hull of a tanker made hundreds of round trips until the erosion of the banks reached a maximum. As a result of these studies, an asphalt mattress, poured over a framework of steel and wire mesh, was designed to slide over the banks of the canal, thus saving in part the endless job of dredging.

Another model showing water flow has been made of the St. Lawrence seaway project. This is a 40-ft. working model of a cutaway section (complete with flowing water), and hydraulic engineers from countries all over the world are able to study from it the interior workings of such a complex operation.

For recreational and hobby purposes, models are constructed and used by children and adults. Generally these are airplanes, boats, railway trains and equipment, automobiles, steam engines or buildings and structures of all sorts. These models may be for display only, or they may be powered by steam or electricity, by motors using gasoline, diesel oil or compressed gases or by jet engines using liquid fuel or compressed gas. The development of plastics and injection molding made possible mass production of model kits which have a quality of fine detail not previously possible at such low cost. The motion-picture industry makes extensive use of scale-modeled sets in order to reduce the cost of photographing sea battles, panoramas or any long-range or altitude camera shots. The theatre uses models of stage settings as a means of testing workability cheaply.

In the armed forces during World War II and the Korean War, modelmaking was used extensively, scaled solid models of planes, ships, tanks and other vehicles being used for recognition training for gunners. Elaborate models were made for tactical purposes, and in several cases scale models were made of entire areas under attack. These models were complete even to the shipping in the harbours and all shore installations, and they were used to ensure co-ordination in joint operations. Models of terrain or manufacturing areas were used to ensure recognition by bombardiers in the various air forces. (G. R. RE.)

**MODENA,** a city in northern Italy, in the Emilia-Romagna region, capital of the province of Modena and seat of an archdiocese. Pop. (1961) 139,183 (commune); province 511,355. The city lies at the centre of the Po valley, between the Secchia and Panaro rivers, 30 km. (31 mi.) E.S.E. of Parma by rail. It is crossed obliquely by the great national road, the Via Emilia (originally a Roman highroad built by the consul M. Aemilius Lepidus in 187 B.C.), which connects Milan with Rimini.

The city's fortified walls, now converted to promenades, give it a pentagonal shape. Inside the walls are open spaces, public gardens and squares and many buildings of historic and artistic interest. Among them are the cathedral, begun in the Romanesque style in 1099 on the site of two former basilicas of the 4th and 8th centuries. Its sculptural decoration is celebrated and the interior contains paintings and sculptures by a number of Renaissance artists. The detached campanile (Torre Ghirlandina), one of the finest in northern Italy, was completed in 1319. Other churches include S. Agostino, called the Pantheon Estense (17th century), a sumptuous baroque edifice; S. Francesco (16th century); S. Giovanni Battista; and S. Pietro (1476), in most of which are preserved works by Antonio Begarelli in terra cotta, a medium for which Modena is particularly well known. The imposing ducal palace, now a military academy, was commissioned by Francis I and begun in 1634. The Palazzo dei Musei houses the municipal collections, of which the more important are the Galleria Estense, rich in paintings of the Renaissance, and the Biblioteca Estense, noted especially for its collection of illuminated manuscripts. The picture collection was given by Francis V in 1869; the library was founded by the Este family at Ferrara in 1393 and moved to Modena in 1598. Modena also has a university, founded in the 12th century. The Aedes Muratoriana, a characteristic Renaissance edifice, contains the tomb of the historian Lodovico Antonio Muratori and a museum.

The modern city, which includes residential and industrial areas, extends outward from the city walls. Among the more important industries are metalworks, cast iron and light alloy foundries, automobile works and factories producing car bodies, machine tools and agricultural machinery. Modena also has a notable cattle market and there are tanning and other leatherwork factories.

The ancient name of the city was Mutina; it was in the territory of the Boii, who were first subdued by Rome late in the 3rd century B.C., and was a place of some importance. The Roman town lay to the southeast of the modern one, its northwestern wall being marked by the Corso Umberto I. The ravages of Attila the Hun and Lombard attacks ruined it, but about the close of the 9th century it was restored. It later became the scene of violent conflicts between the Guelphs and Ghibellines until the 13th century, when it became a possession of the house of Este (*q.v.*), with whom its history is closely identified. The next to the last of the Este rulers, Francis IV, duke of Modena, was reactionary and despotic; his son, Francis V, who succeeded him in 1846, faced internal difficulties from the beginning and in 1859 the representatives of Modena declared their territory part of the kingdom of Italy. Their decision was confirmed by the plebiscite of 1860.

The province, covering an area of 2,690 sq km. (1,039 sq mi.), has a diversified economy which includes agricultural production, cattle breeding, food and clothing production and ceramic and brick factories. Among the urban centres are Vignola, 20 km. (12 mi.) S.E. of Modena, known for its fruit; Sassuolo, 16 km. (10 mi.) S.W., with ceramic and brick factories; and Carpi, 15 km. (9 mi.) N.W., with textile industries. Among the food products produced in the region are grapes from which wine is made, cheese, ham and sausage.

**MODERN ARCHITECTURE.** This article is concerned with architecture after 1800 and is divided into the following main sections:

I. Introduction
II. The 19th Century
  A. Background
  B. From 1800 to 1860
    1. Rationalism
    2. Classicism
    3. Romanticism
    4. Organicism

## I. INTRODUCTION

Architecture after 1800 shared with earlier architectures three diverse requirements: to render good performance; to stand up and sustain loads; and to give aesthetic satisfaction. The buildings necessarily reflected the society in which they were created; they especially reflected the acquisition of technological control over natural power and the application of technology to problems of manufacture, distribution, transportation, communication, climate and physical comfort.

The greatest amount of energy was expended upon housing modern entrepreneurial management. The characteristic building types were the powerhouse or dam, the factory, the research laboratory, the administrative office building, the transportation terminal and the market. Architecture became the badge of commercial prestige, an advertisement of the new centres of power which sought in height, size and quality the architectural eminence accorded in the past to churches and places of political assembly.

Until about 1900 it was not clear that a new style of architecture would accompany the new institutions. Many architects and clients attempted to enshrine science and commerce, the new metropolis and its suburban fringe, within classical and medieval styles. Others subscribed to a cultural schism, allowing the factory and powerhouse to be bold, inartistic expressions of engineering while buildings at the top of the social hierarchy, the church and the college, were made to conform to Gothic, colonial or Roman antecedents.

Thus most 20th-century cities were cacophonies of architectural styles as clients and architects were guided by any of four contrasting ideas: formalism and romanticism, drawing upon classical and medieval precedents, respectively; mechanism, a hypothesis about nature extended to architecture; and organicism, a composite of romantic and mechanistic philosophies. The proponents of formalism, such as Charles Follen McKim, believed that beauty was obtained through the manipulation of cylinders, hemispheres and other simple geometric forms after Greek or Roman models. Arranged upon axes, these forms constituted impressive monumental buildings, Henry Bacon's Lincoln memorial in Washington, D.C. (dedicated 1922) being one example. John Ruskin and Ralph Adams Cram advocated romanticism. The complex spaces and structures of Gothic cathedrals were recreated in St. Thomas' church in New York city (1913) by Bertram Goodhue and in the University museum by Thomas Deane and Benjamin Woodward at Oxford, Eng. (*c.* 1858). The third idea, mechanism, the ancient philosophy of nature by which the universe was interpreted as a system of uniform laws governing inert masses, suggested an emphasis on structures and materials and on the efficient, economical adaptation of form to use. It gained support among such architects as Walter Gropius, who established the Bauhaus (*q.v.*) on principles compatible with those of science and industry. Still another point of view, organicism, was espoused by the great architect Louis Sullivan, who insisted that living organisms provide the formal, structural and adaptational principles of architecture. "Fallingwater," Bear Run, Pa., was designed by Sullivan's pupil Frank Lloyd Wright.

However suggestive for style, the four philosophies offered little basis for quality, which is a function of architectural design rather than style. Too few clients and architects realized that quality in architecture derives from a rhythmical arrangement of spaces and masses, which states a geometric theme in light and shade, expresses its purpose and executes that purpose well. The style may express a building's site, materials, use, structure, client, designer, interior spaces, era or social environment, but such expressions have nothing whatever to do with the utility (emotional as well as physical), stability or beauty of the result. Failure to understand the differences between style and composition contributed to the poor architecture of modern communities in instances such as those in which a Georgian, classical or Gothic style was chosen as being appropriate to a town, church, college or office building, however unsatisfactory the architectural result might be. (See ARCHITECTURE: *Expression.*)

Good modern designs might achieve unity through the use of interlocking, dynamically asymmetrical masses and spaces, as in the town hall at Hilversum, Neth. (1924), by W. M. Dudok or Ludwig Mies van der Rohe's German pavilion at Barcelona (1929), or by balancing similar voids or masses symmetrically with respect to an axis, as in the Galleria Vittorio Emanuele at Milan by Giuseppe Mengoni (1829–77) or the railroad station at Tours by Victor Laloux (1850–1937). The former arrangement characterized programmatic buildings, in which interior spaces were extruded to create salient, exterior masses, as in the Graduate centre at Harvard university (1950) by the Architects' Collaborative or Le Corbusier's Notre Dame du Haut at Ronchamp (1955).

The latter type of composition, sometimes called monumental, prevailed wherever regular geometric enclosures were practical, as in the intersecting barrel vaults of the Lambert-St. Louis (Mo.) air terminal (1950–56) by Minoru Yamasaki or the spherical triangle of the auditorium at the Massachusetts Institute of Technology (M.I.T.), Cambridge (1955) by Eero Saarinen. In each case, the successful building marked a graceful transition from the ground, terminated at the corners decisively, came to a forceful conclusion at its sky line and formed successful interior and exterior spaces with amenable transitions between them. Usually, a single spatial theme was varied rhythmically throughout the building, as in Frank Lloyd Wright's Johnson Wax company administration building at Racine, Wis. (1936–39), where the theme was a cylinder of space. Modern architecture must be judged on both its style—the building's expressive content, particularly as it reflects the people and institutions that built it—and its design—the organization of masses and spaces to achieve both a useful and an aesthetic result. Not all modern buildings were successful by either of these criteria, and only a few by both.

## II. THE 19TH CENTURY

### A. Background

The architectural theories that were ascendant during the 19th and 20th centuries were already operative during the 18th century. Formalist theories, derived from Renaissance ideas, were reflected in the works of Jacques François Blondel (1705–1774), in buildings like the Petit Trianon (1762–68) by J. A. Gabriel and in James Gibbs's St. Martin-in-the-Fields (1722–26). There were mechanists, such as Francis Hutcheson, Carlo Lodoli and the abbé Laugier. "Rationalist" architecture, exemplified by George Steuart's St. Chad's at Shrewsbury, Eng., Sir John Soane's Bank of England and C. N. Ledoux's plans for Chaux, an ideal village for France, was functional and programmatic in plan and classical in style. There were also utilitarian buildings; the factory at Soho, Eng., for instance, showed the intention of Matthew Boulton and James Watt to use iron and masonry economically in industrial buildings. Most evident were the romanticists. Archaeological investigations during the 1750s by R. Wood and J. Dawkins at Palmyra and Baalbek, by D. Leroy in Greece, by J. Stuart and N. Revett in Athens inspired a classical temple at Hagley, Eng., while C. L. Clérisseau's investigation of the Maison Carrée at Nîmes allowed Thomas Jefferson to reproduce the major features of that Roman building for the state capitol at Richmond, Va. The far east was the inspiration for a "pagoda" at Kew gardens. Marie Antoinette's peasantlike Petit Hameau at Versailles occasioned delight among the lovers of the rustic. Horace Walpole's Strawberry Hill expressed the enchantment with the Gothic that made Sir Walter Scott's works so popular. Scott himself built a

"Gothick" house at Abbotsford, Edinburgh, begun in 1812. *See* also BAROQUE AND POST-BAROQUE ARCHITECTURE.

B. FROM 1800 TO 1860

**1. Rationalism.**—Throughout western Europe and the eastern U.S. in 1800, remnants of Renaissance architectural forms survived until architects consciously revived them wholesale. Two clubs in London, the Reform (1837) by Sir Charles Barry and the Athenaeum (1829–30) by Decimus Burton, the latter a reflection of Baldassare Peruzzi's Palazzo Massimo at Rome, established the setting for the cultured English gentleman as the Renaissance *palazzo*. Dorchester house, London, by Lewis Vulliamy was a frank copy of the Villa Farnesina at Rome. The fashion also prevailed for churches, as in Arthur Gilman's Unitarian church on Arlington street, Boston, which was modeled upon Italian examples, and for department stores. In J. P. Gaynor's Tiffany store at New York city, the *palazzo* form, however much prestige it conveyed, was stretched into an absurdity.

Rationalist architects recognized the incongruity of Renaissance enclosures for modern institutions. One of the most interesting designers, Sir John Soane (1753–1837), in a series of buildings including the Bank of England (remodeled 1792–1823), the Dulwich Art gallery (1812), the stables at Chelsea hospital (1810) and his own house at Lincoln's Inn Fields (1812–14), created exterior masses out of interior spaces, achieved dramatic and unusual combinations of parallelepipeds and hemispheres and established innovative proportions. In Germany K. F. Schinkel (1781–1841), working in a variety of styles, attempted programmatic planning in his Royal theatre at Berlin (1818–21), St. Nicholas church at Potsdam, Altes museum at Berlin (1822–30) and "Project for a Department Store." His Academy of Architecture at Berlin (1831–35) was the most effective of his attempts to shed classical and medieval precedents.

In the U.S. rationalist architecture was introduced by the Frenchman J. J. Ramée, who designed buildings for Union college, Schenectady, N.Y., in 1813, and by the Englishman Benjamin Henry Latrobe (1764–1820), whose waterworks at Philadelphia (*c.* 1800) and Roman Catholic cathedral at Baltimore (*c.* 1820) perfectly reflected the desire for useful and theatrical spaces enveloped by classical forms. Such designers did not imitate classical precedents; Latrobe, for example, designed tobacco and corn orders for capitals in the senate rotunda at Washington. Native American architects soon caught the spirit; Charles Bulfinch (1763–1844) moved away from the academic design of his statehouse at Boston toward the rational composition of University hall at Harvard (1813–15), a direction later followed by Robert Mills (1781–1855) not only in his Washington monuments at Washington and Baltimore but in the Sansom Street Baptist church in Philadelphia (1808) and the jail at Charleston, S.C.

**2. Classicism.**—Latrobe attempted to dissuade amateur architects such as Thomas Jefferson from sacrificing utility for the sake of Greek and Roman details, but the classical revival swept many countries, sometimes leaving elegant legacies. Beginning about 1815, architecture and archaeology became more closely allied. H. W. Inwood and C. R. Cockerell increased the store of information about Greek architecture. Lord Elgin removed the Parthenon's pedimental sculptures and their deposit in the British museum in 1816 added to the then current interest in ancient Greece. This Hellenism became more fervid when, from 1821 to 1829, the wars of Greek independence inspired Englishmen such as Lord Byron and Americans such as Nicholas Biddle to become ardent supporters of the Greek cause. The classical theme was used at George Basevi's Fitzwilliam museum at Cambridge and Harvey Elmes's St. George's hall at Liverpool. Inwood's church of St. Pancras, London (1819–22), pedantically and eclectically repeated themes from the Athenian Tower of the Winds, Choragic monument of Lysicrates and Caryatid porch. The Edinburgh high school (1819, D. Hamilton) was the Thesenm (Hephaesteum) on the front of an academic building. Classical romanticism was in the architectural forefront in France also, where Napoleon's imperial aspirations left a monumental civic residue in the Arc du Carrousel, Paris (1806) by Charles Percier and Pierre Fontaine, and the church of the Madeleine, Paris (1806–42), by Pierre Vignon, which was intended to be a "temple of glory" for Napoleon's legionnaires. In Germany, meanwhile, under the influence of J. J. Winckelmann (1717–68), Goethe and Lessing, interest turned toward Greek archaeology. The architect F. K. L. von Klenze designed a "Valhalla," a Greek temple standing on an artificial hill at Regensburg in frank imitation of the Parthenon on the Acropolis. The Brandenburg gate at Berlin by K. G. Langhans (1733–1808), the Siegestor at Munich (1840) and the Aula at Göttingen established the precedent of antique settings for the gateways to cities and universities.

The U.S. succumbed to the charm of Greek and Roman architecture during the period from 1815 to 1860. Following his apostrophe to Roman Nîmes in the state capitol at Richmond (1785–92), Thomas Jefferson put his practical mind and elegant taste to the design of a university campus, the University of Virginia, Charlottesville (1817–25), where his plan for "an academical village" ensured privacy for students and professors and protection from inclement weather. It was dominated by the library rotunda, a copy of the Pantheon; and the pavilions, which punctuated the rhythms of low-lying dormitories in the lawns, imitated Roman and Palladian designs. Acceptance of Greek or Roman precedent in decorative details frequently required it in other matters, but in the hands of professional architects, Francis Costigan or Gideon Shryock for example, space was adeptly handled to achieve both utility and visual coherence, best exemplified by Shryock's state capitol at Frankfort, Ky., and in a building now recalled only by drawings, Bussière de Pouilly's St. Louis hotel at New Orleans (1836–40). Lesser designers graced the towns of Marietta, O., Ovid, N.Y., and Nantucket, Mass., with Greek and Roman temples, which in many cases remain the towns' finest embellishments. They offered no sound approach to an architecture for modern times, however, and failed to express modern ideas even in the Merchants' Exchange William Strickland erected in Philadelphia in 1834. Deluded by extraneous political symbolism, Americans housed state legislatures in classical ideograms, as at Columbus, O. (Henry Walter), New Haven, Conn. (1827, Ithiel Town), and Indianapolis, Ind. (1832–35, Town and Alexander Jackson Davis). Stephen Girard's express wishes for serviceable and simple buildings at the college he founded at Philadelphia were ignored by his trustee, Nicholas Biddle, who persuaded the architect, Thomas Ustick Walter, to make the main building (1833–47) a Greek temple with Corinthian columns; its rooms were poorly lighted, ventilated and reverberative. At its dedication Joseph Chandler spoke of its power to evoke classical grandeur and to inspire moral virtue. Greek houses, such as the one planned and owned by J. C. Stevens in New York city (1845), were sometimes ingeniously planned. Another amateur in New York, Philip Hone, noted in his diary that every departure from classical models seemed to him a departure from grace and beauty.

**3. Romanticism.**—In England, where Gothic construction still survived in rural regions, there was a conscious revival of medieval forms. Beginning with schools, colleges and churches, *e.g.*, St. Luke's, Chelsea (1820–24), by J. Savage, the fashion was stimulated by the Oxford movement and Camden Ecclesiological society and it received national approval when, from 1837 to 1857, the Houses of Parliament were rebuilt. The 97 designers who submitted drawings engaged in a battle of styles, Gothic versus classical. Gothic, which was thought to be more patriotically English, more manly and closer to nature, emerged triumphant. An academic, regular plan, preserving the old Westminster hall, enabled the architect, Sir Charles Barry (1795–1860), to fit the new quadrangles to the old hall, while the young designer Augustus Welby Pugin (1812–52), passionate advocate of Gothic architecture, ornamented the Gothic Revival elevations. At Ramsgate, Pugin designed the Gothic chapel of St. Augustine (1846) and, at Southwark, the cathedral of St. George. Equally active as a writer, he advocated Gothic, above all others, as a Christian architecture, a point of view he stressed in *Contrasts, or a Parallel Between the Architecture of the 15th and 19th Centuries* (1836) and *True Principles of Christian Architecture* (1841), in which his

basic, but highly debatable, assumption was that architecture that is aesthetically good nurtures a society that is ethically good.

Pugin gained some following on the continent. Frenchmen seldom accepted moral interpretations of medieval architecture and with a few exceptions, such as Chateaubriand's house at Châtenay (remodeled 1807) and the chapel of St. Louis at Dreux (begun 1816), they frowned on Gothic Revival. English influence was stronger in Germany, where the brothers Schlegel awakened interest in Gothic buildings. Cologne completed its medieval cathedral; and there were also new Romanesque buildings such as the Johanniskirche in Berlin (1835) by Schinkel, and picturesque Gothic castles, such as the Schloss at Neuschwanstein, Bavaria (1869–86), built for Louis II who, appropriately, invited Richard Wagner to visit him there after the "Ring" series was published.

Medievalism also flourished in the United States. Pugin gained an American following quickly, including the Episcopal bishop J. H. Hopkins, who wrote an appreciative essay about Gothic in 1838. Alonzo Potter, also a bishop, Henry Cleveland, professor of history at Harvard, and Andrew Jackson Downing, a landscape architect and architectural journalist, championed Gothic for use in churches, schools, public buildings and houses. The response was immediately favourable and James Renwick designed Gothic churches for New York's Episcopalians (Grace church, 1843–46) and Roman Catholics (St. Patrick's cathedral, 1858–79). Richard Upjohn (1802–78) matched Renwick's scholarship by erecting New York's Trinity church (1839–46) and surpassed his rival's range of expression with rustic rural churches employing board and batten construction. Gothic villas appeared in the countryside, often in picturesque compositions as in Upjohn's "Kingscote" at Newport, R.I. (1838), and in the villa for Charles Alger at Berkshire, Mass., designed by A. J. Davis (1803–92). Gothic church forms were used at colleges and universities, sometimes in a militaristic manner, as at the Virginia Military institute at Lexington (*c.* 1850) by Davis, or, more often, to suggest the affiliation between humanistic education and Protestant worship, as in New York university's main building (1836) and Yale's library (1842), both by Davis, and Harvard's Gore Hall library (1838), a clumsy version by Richard Bond of King's College chapel. Stretched still further, medieval forms served modern transportation, as in Thomas Tefft's design for Union depot at Providence, R.I. (1848).

The motivation behind this revival was to create a setting redolent of medieval piety and rich in moral associations. Literary associations and the fancied emotional nuances of simulated masonry vaults distracted attention from the true matrix of architectural experience, but they were beguiling.

Romantic clients and architects did not long remain content with classical or medieval reminiscence. There were also rich quarries in other historic and distant architectures. Memory sometimes slipped and an Islamic temple was built for Jews, as in J. K. Wilson's Plum street temple in Cincinnati, O. Egyptian obelisks appeared in Paris and Washington, cavetto cornices in Paris (Hôtel de Torcy, remodeled for Napoleon's stepson). Egyptian columns in New York (the Tombs, a prison, 1838, John Haviland), New Bedford, Mass. (the Pearl street railroad depot), and Cambridge, Mass. (the Mount Auburn cemetery gates). Early Christian basilicas were called to mind by the church of St. Vincent de Paul in Paris (1824–44) by J. I. Hittorff (1792–1867) and picturesque Italian villas appeared on the hills of England and the U.S. ("Prospect," Princeton, N.J., 1849, John Notman). Even more exotic were the Indian, Chinese, Japanese and Persian pleasure palaces, such as the Royal pavilion at Brighton, Eng. (1818–21), by John Nash and "Iranistan," P. T. Barnum's domed extravaganza at Bridgeport, Conn. (1848). Such eclecticism was encouraged by critical writing, which was best represented by A. J. Downing's *Landscape Gardening* (1841), *Cottage Residences* (1842) and *The Architecture of Country Houses* (1850).

**4. Organicism.**—Some persons proclaimed a day in which historical stage-sets would have no place. Perhaps the most cogent was Horatio Greenough (1805–52), a sculptor who recognized in the work of Schinkel and Latrobe the possibility of an architecture appropriate for modern institutions. It would provide useful spaces, light, air and protection from weather; its spaces would be defined by means of classical walls and columns, ornamented in ways relevant to modern society. Greenough was openly critical of Girard college's temple, saying it was "like seeing the Pitt diamond on an Indian squaw." Equally critical of the medieval towers and battlements on Renwick's Smithsonian institution in Washington, Greenough said, in a dramatic twist on the associationalist's argument, that they were expressive, admittedly, but of a politics and a religion that were foreign to those he believed America should have. He delighted in the structure of ships, bridges, hand tools and weapons, and his study of the anatomy of birds and plants led him to a far-reaching principle: form adapts to use. This organicism appeared in the writings of Ralph Waldo Emerson and the critics at Concord.

**5. Mechanism.**—A more mechanistic viewpoint emphasized the need for economical, utilitarian buildings. John Willis Griffiths, a naval architect, lectured in the eastern United States at mid-century about his revolutionary "extreme clipper ships," saying that strict adaptation of form to functional purpose was the only source of beauty and utility. His viewpoint reflected that of the industrialists who erected the Stanley mill in Stroud valley, Gloucestershire (1813), and the Allendale mills at Centerdale, R.I. (1822). Utilitarianism was the objective of engineers like Sir William Fairbairn, who was responsible for the mills at Saltaire, Eng. (1851–53). Perhaps the strongest proponents of utilitarianism were scientists, notably Joseph Henry, the U.S. physicist, Sir Francis Galton, the English physician, and Alfred Russel Wallace, the English biologist, who wanted functional laboratories, hospitals and museums, without wasteful expenditures on monumental galleries, staircases or vaults.

Characteristic of the serviceable, economical and flexible workrooms they wanted were the spaces in Harvard's Museum of Comparative Zoology, designed by the Swiss biologist Louis Agassiz in 1859. The rooms were excellent for displaying a typologically arranged exhibit of biological specimens, but the pile of brick was as ugly as if it had been tossed up by a prehistoric glacier. In rejecting all considerations of design as well as style, the mechanists accomplished an architectural result that was no more satisfactory than the eclectic chimeras of romantic fancy. Physical utility could not be ignored, but a building, to be architecture, had also to be an aesthetic expression of the great themes science and industry suggested.

**6. The Beaux-Arts.**—The dilemma was frequently avoided by architects of the academic tradition in France, particularly those from the École des Beaux-Arts in Paris. The most fruitful architectural school of the 19th century, it sought to furnish utility within handsome, classical buildings. Traditional elements, such as domes and columns, and traditional principles of composition, including geometric spaces balanced around axes, characterized the work of J. L. Duc and J. L. Pascal. A more radical part of the École group, led by Henri Labrouste (1801–75), attempted programmatic plans and nonarchaeological use of classical forms. Labrouste's Bibliothèque Ste. Geneviève (1843–50) and Bibliothèque Nationale (1854–68), both in Paris, were eminently successful, not only in the harmony of their spaces, but in the expression of programmatically arranged interiors and the introduction of useful devices such as iron stacks and cast-iron structure. More conservative designers, L. Visconti and H. Lefuel, for example, worked upon additions to the Louvre, in which they imitated earlier portions to achieve harmony (Louvre pavilion, 1852). Victor Baltard, however, in the church of St. Augustin (1860–68) and the Halles Centrales (1853), the central markets in Paris, used iron and glass in his programmatic arrangements of space. Baron Georges Haussmann directed Baltard and other architects in the design of the great boulevards of Paris: grand axes connected principal historic buildings and established prominent sites for monuments like the Arc de Triomphe de l'Etoile at the head of the Champs-Élysées by J. F. T. Chalgrin (1739–1811). Much of the present character of Paris remains a tribute

to Haussmann; although his despotic methods were seldom available to later city planners, the example of Paris long remained a model for modern urban patterns.

### C. From 1860 to 1885

Haussmann's example, following Labrouste's innovations, ended any search for ancient buildings that might be appropriated wholly to contain modern institutions. Museums, markets, office buildings and schools demanded new and complex plans and the best designers provided them, although they did not originate a compatible style. They attempted instead modern versions of classical and medieval styles. Perhaps the most exciting of the new sequences of space can be seen in a longitudinal section of the Opéra at Paris (begun 1861) by the Beaux-Arts architect Charles Garnier (1825–98); grand entrances, foyers, staircases, vestibules and boxes lead to a huge auditorium, which is separated from the office wing by a tall stage loft. Garnier's magnificent command of the sweeping spaces was equaled by his mastery of balance, punctuation and termination; the façade, a composition of stately rhythms and playful sculpture, provided a fitting entrance for Napoleon III.

**1. Ruskin's Influence.**—Nothing comparable appeared in the United States or England during the '60s and '70s. In these countries there was a continued insistence upon the literary appropriateness of Gothic sculptural details. The high priest of medieval sentiment at this time was John Ruskin (1819–1900), who preached the aesthetic and moral excellence of the doge's palace at Venice and the campanile at Florence and convinced young architects that medieval handicraft ways might change modern civilization. His *Seven Lamps of Architecture* (1849) and *Stones of Venice* (1851–53) inspired the architect Thomas Deane to essay polychromy and hand-carved ornamental capitals at the Engineering building for the University of Dublin (1851). With Benjamin Woodward, Deane designed the University Museum of Natural History at Oxford university (1854–60), where the brothers O'Shea were exhorted to carve decoration after the natural foliage of the region. Other Englishmen joined the medieval brotherhood. The most influential was William Morris (1834–96), a poet, novelist and artist, a great printer and a leading socialist (*see* Arts and Crafts Movement). He attempted to counteract the ugliness of much machine production by reviving the guilds and by espousing medieval principles, especially those regarding the expression of materials, structure and utility. Together with an architect, his friend Philip Webb, he created the Red house at Upton, Kent, in 1859, where brick, glass, shingles and interior spaces were expressed frankly and boldly. More ornate architecture was improvised on medieval themes by Alfred Waterhouse, William Butterfield and William Burges. Their versions of Gothic, called Victorian, are suggested by the St. Pancras station's Midland hotel (1865) and Albert memorial (1863–72), London, by Sir George Gilbert Scott (1811–78) and by George Edmund Street's New Law courts, London (1874–82). Occasionally, R. Norman Shaw turned out a well-composed version of Tudor Gothic in which massive blocks were chastely mounted to form a picturesque composition. But restraint in the use of ornate, flaccid and tortured forms was rare and the '70s and '80s gained a reputation as a period of notoriously bad taste.

In the U.S. some architects, clients and critics considered Victorian Gothic architecture to be a way of providing a colourful foil to the ugly urban and industrial scene. Ruskinian sentiment captured the hearts of a group in New York who founded the Association for the Promotion of Truth in Art. One of its members, Peter Bonnett Wight, designed the National Academy of Design (1862–65), in which capitals were carved by hand ("to give workmen opportunity to think," according to Wight). The building was a restudy of the doge's palace at Venice, and was meant to please Ruskin. Next, Wight moved his sculptors to New Haven, Conn., where they erected the Street School of the Fine Arts at Yale, another Ruskinian building. *The Crayon* and *The New Path*, periodicals promoting Ruskin's ideas, found favour with Charles Moore and Charles Eliot Norton in Cambridge, Mass., both friends of Ruskin, who was benignly moved by Norton's efforts to improve the architecture at Harvard university. Harvard's Memorial hall (1866–78), designed by W. R. Ware and Henry Van Brunt, was a major statement of Victorian Gothic environment. Such buildings were especially popular for educational institutions, such as Princeton university (Chancellor Green library, 1873, William A. Potter) and Trinity college (later Duke university, Durham, N.C.; quadrangle, 1876, Burges), as well as for museums of fine arts and concert halls in New York, Boston, Cincinnati and Chicago. Even courthouses and post offices tended to be Victorian Gothic while Potter was supervisory architect of the treasury. Some churches, notably the New Old South Congregational at Boston (1877, Cummings & Sears), revealed dramatic spaces, interesting structures and fascinating silhouettes, but the overtones of the architecture were literary and symbolic.

**2. Viollet-le-Duc.**—During the 1880s, architects and critics who became disenchanted with Ruskin's peevish moralism turned to a Frenchman, E. E. Viollet-le-Duc (1814–79), whose archaeological work on Notre Dame de Paris, Carcassonne and other medieval sites led him to respect Gothic architecture as a coherent structural system. His *Dictionnaire raisonné de l'architecture française*, published between 1854 and 1868, was an encyclopaedia of exact information, and his *Entretiens sur l'architecture*, published between 1860 and 1872, developed his general theory, which he formulated for lectures he delivered at the École des Beaux-Arts. Translated into English, the *Lectures* stimulated John W. Root and other Chicago architects to attempt what they called "rational architecture," which was based on frank expression of structure. Although Viollet-le-Duc himself was not a talented architect, as he demonstrated in the gross Gothic Revival church he built at St. Denis, his *Lectures* offered important information about the construction of modern iron skeletons enclosed by nonbearing masonry walls. Illustrations in his book indicated the possible uses of metal, which were exploited in an important building, the Menier chocolate works at Noisiel-sur-Marne (1871–72), by Jules Saulnier. Architects generally ignored Viollet-le-Duc's suggestions, but some did attempt more robust structures, such as Philadelphia's Provident Life and Trust Company building (1879) by Frank Furness and those in the same city by Wilson Eyre, Jr., whose medievalism was more whimsical.

**3. New Forms.**—Scientists continued to have little sympathy for medieval forms. In 1876 Thomas Huxley, the English biologist, advised the trustees of the new Johns Hopkins university at Baltimore not to allow funds to "fossilize into mere bricks and mortar" and to "hire an honest bricklayer" who should erect only useful structures. The physician John Shaw Billings designed the ward pavilions at the Johns Hopkins hospital, while professors of chemistry, biology and physics designed their own laboratories. The president, Daniel Coit Gilman, wanted modern, serviceable structures such as he saw in laboratories at German and English scientific institutes, for example, the chemistry laboratory at Manchester, Eng., which was a bald working machine designed by a professor of chemistry, H. E. Roscoe. Gilman criticized the expensive and unsatisfactory medieval piles at Trinity college and Edinburgh (George Gilbert Scott). His opinion was shared by Charles William Eliot, Harvard's president. A chemist, he had planned his own laboratory at M.I.T. and had high regard for buildings that were expandable, flexible and even expendable, since progress in science required frequent rebuilding. Critics like Clarence Cook now somersaulted from Ruskin's troupe to that of the scientists, whose aesthetic tastes were typified by Gilman's admiration for the precision, uniformity and economy of nature and of fine instruments and machines. Unfortunately, no architect could supply compatible buildings.

Had the scientists recognized it, there was an incipient new architecture that might have reconciled the differences between those who, wanting useful, economical buildings, settled for the commonplace work of bricklayers and mechanics and those who clung to medieval and classical forms to satisfy their craving for art. One could see the dichotomy even within a single building, as in London's St. Pancras station, where Scott's Gothic building stood alongside the iron and glass vaults of the train shed, without

any attempt at a resolution. The shed (1868) was designed by an engineer, W. H. Barlow. Metal arches hold a canopy of glass in a powerful, grand grasp of space. Engineers designed with new materials, exposing them and shaping them in accordance with function rather than a whim of historical taste. At most, architects used cast-iron columns and ribs to simulate traditional domes, as in Nash's Royal pavilion at Brighton, Sir Robert Smirke's British museum (1823–47) and Thomas Walter's dome on the United States Capitol (1851–65).

Builders who were less bound by history achieved new forms. In the Crystal palace at the Great exhibition held at London in 1851, a botanist, Joseph Paxton, employed timber, cast iron, wrought iron and glass in a ridge-and-furrow system he had developed for greenhouses at Chatsworth in 1837. Paxton was partly inspired by the organic structure of the Amazonian lily *Victoria regia*, which he successfully cultivated. The Crystal palace contained important innovations in mass production of standardized materials and rapid assembly of parts, but its chief architectural merit lay in its cadence of colossal spaces. French designers recognized its magic, and a series of buildings for universal exhibitions held at Paris in 1855, 1867 and 1878 showed its influence. In the Palais des Machines (1889) by Ferdinand Dutert and M. Contamin a series of three-hinged trussed arches sprang, from small points, across a huge space, 385 ft. long and 150 ft. high. The English historian James Fergusson happily concluded that the Crystal palace marked the beginning of a new architecture; an English critic, Thomas Harris, coined the name "Victorian" for 19th-century architecture and looked forward to an age of iron buildings. The most important emblem of the Paris exhibition of 1889 was the Eiffel tower (1887–89), designed by Alexandre G. Eiffel, an engineer, who had done outstanding work in the Paris exposition of 1878 and in steel structures like the trussed parabolic arches in the viaduct at Garabit, France (1880–84).

The new materials and forms were best introduced in the service of new architectural problems, such as railroad stations, which could not for long be contained within Renaissance palaces or Gothic guildhalls. As railroads became larger, they sought expressions of the fast and comfortable travel they offered; as they became chief gateways to cities, the stations acquired a distinctive, monumental character. The architectural progression can be followed: the motley, utilitarian Crown street station in Liverpool (1830) and Mount Clare station in Baltimore (1830) gave way to the Classical Revival Boston and Lowell "car house" at Lowell, Mass. (1835). New forms were sought in the arches, trusses and skylights of Sir William Tite's Nine Elms station at London (1837–38). The pagodalike towers on Henry Austin's Union station at New Haven, Conn. (1848–49), were a whimsical diversion, to be followed by Philip Hardwick's dignified Euston station, London (1839–40). All of this culminated in the Parisian Gare de l'Est (1847–52) by François Duquesnoy and Gare du Nord (1861–65) by Hittorf and F. L. Reynaud, London's King's Cross station (1851–52) by Lewis Cubitt, Berlin's Alexanderplatz Bahnhof (1880–85) by J. E. Jacobsthal, the St. Pancras at London and the station at Tours (1895–98) and Paris' Gare du Quai d'Orsay (1898–1900) by Laloux.

The emancipation of markets and stores was no less impressive. Designers erected iron and glass umbrellas such as Baltard's Halles. Members were admitted to the Coal Exchange in London (1846–49, J. B. Bunning) through a round, towered classical porch at the corner of two Renaissance palaces, to a magnificent rotunda hall, which was surrounded by three tiers of ornamental iron balconies and roofed by a lacelike dome of iron and glass. At Paris Eiffel, together with the architect L. A. Boileau, gave the retail shop a new and exciting setting in the Bon Marché (1876), where merchandise was displayed around the perimeters of skylighted, interior courts. The U.S. saw nothing comparable, but cast-iron columns and arches, appearing during the '50s, were used in commercial buildings like the Harper Brothers building at New York by John B. Corlies and James Bogardus (1849) and the *Baltimore Sun's* Iron building by R. G. Hatfield. Stores were given cast-iron faces, as in the pioneering Stewart's department store (later Wanamaker's) in New York city (1859–62) by John Kellum. Iron was frequently intended to simulate stone, and it was admired for its economy of maintenance. The material offered such neglected qualities as precision, standardization and efficient strength, however, which Van Brunt hoped would be recognized architecturally.

Unfortunately, the architects' society restricted their adventures into innovative spatial composition. The train shed was hidden behind the classical or Gothic waiting room; the skylight was thrust out of sight, as at the Bon Marché. Bold engineering was permitted in a bridge or warehouse, but time-honoured cultural institutions demanded an appropriate, traditional expression. In Germany the eclectic Renaissance architecture of Gottfried Semper (1803–79) and Alfred Messel (1853–1909) was dominant. There might be some simplification of form, as in the late work of England's Shaw or the studio (1888) of C. F. A. Voysey (1857–1941) at Bedford Park, London, and Voysey's house for Canon Grane at Shackleford, Surrey (1897). Amsterdam's Bourse (1898–1903) by H. P. Berlage (1856–1934) showed strong bold forms but there were still the traditional ones, as in the town hall at Copenhagen by Martin Nyrop (1849–1921), and little innovation was attempted in structure or materials.

**4. H. H. Richardson.**—Perhaps the architect's position during the '80s was best illustrated by the career of the American Henry Hobson Richardson (1838–86). A gentleman from a fine southern family, he graduated from Harvard, then attended the École des Beaux-Arts in Paris. Returning to New York and going later to Boston, he cast aside his weak Victorian Gothic and Napoleon III pavilions and won national acclaim for the bold and heavy masses of his Trinity church at Boston (1872–77) in which Romanesque motifs from Arles and Salamanca embellish a cruciform auditorium intended for the great preacher Phillips Brooks. The Sherman house at Newport, R.I. (1874–76), recalled Richardson's earlier mélange of styles, but it also hinted at an elimination of complications. He found his stride in his designs for small public libraries at Medford, North Easton and Quincy, Mass., and for small suburban stations along the Boston and Albany railroad tracks.

Like all great designers, Richardson recognized the need for the monumental, even subordinating utility to achieve a unified result, as in the handsomely proportioned Sever hall at Harvard (1878–80). He could be rustic, as in the gate lodge for the Ames estate at North Easton; he was adept in revealing the nature of wood shingles, brick, terra cotta and stone, as in his houses at Cambridge, St. Louis and Chicago; and he also mastered dynamic, programmatic compositions with strong silhouettes, realized in gargantuan stone, as in his Allegheny county courthouse and jail at Pittsburgh (1884–86). His short career ended while his Marshall Field wholesale warehouse (1885–87) was being erected at Chicago. The importance of this warehouse lay in its art. Its masonry arches, which were on a scale compatible with 19th-century commercial and industrial power, stated in light and shadow a theme that was terminated at the corners, phrased in a quieter way above and concluded by a cornice. The warehouse gave later architects in Chicago their first glimpse of how stone might spring to life in the service of industry, and its lesson, usually with more emphasis on the Romanesque Revival style than on the great composition, spread to Kansas City (Van Brunt & Howe), New York city (Potter & Robertson), Boston (Shepley, Rutan & Coolidge) and Minneapolis (L. S. Buffington).

### D. From 1885 to 1900

Still another attempt to instill modern vigour into traditional architecture was made by classicists, especially those who were centred around the École des Beaux-Arts. French students underwent a rigorous training, clearly defined in *Éléments et théorie d'architecture* (c. 1900) by Julien Guadet, a professor at the École. In their best work, such as the Grand Palais and Petit Palais in Paris (1897–1900) by Charles Girault, the French Beaux-Arts architects employed iron, steel and glass in combination with masonry; they organized plans and spaces for clear circulation, monumental vistas and expression of use and they were inventive in elevations and ornamental detail while preserving classical principles of composition. Germany, Russia, England and Italy fol-

lowed the French lead, as in Mengoni's Galleria Vittorio Emanuele at Milan (*c.* 1865). Americans also attended the École, beginning with Richard Morris Hunt (1827–95), and, although Richardson abandoned classicism for the Romanesque style, most Beaux-Arts graduates followed the style that was dominant at Paris. At its worst, the Beaux-Arts influence resulted in atrocious decoration, wasteful plans, inefficient structures and monuments that had little to say about their times. About 1875 inferior architects, such as A. D. Mullet, were in control of the design of most public buildings, and the Old Post Office in New York city, the State Department building in Washington and the city hall at Philadelphia show a reckless display of classical detail unchecked by the knowledge good Beaux-Arts designers invariably brought to their work. The commendable work of Hunt, such as the "Breakers" at Newport (1893–95) and the "Biltmore" at Asheville, N.C. (1890–95), and the more meritorious designs of the French critic at M.I.T., Constant Désiré Despradelle, as in his Berkeley building, Boston, could not prevent the Beaux-Arts from acquiring a bad reputation. Even after it lost its vigour, however, its best exponents were enviably skilled in planning, drawing and monumental composition.

Departures from classicism were numerous during the '80s and '90s. In England and the United States, Gothicists like Sir Giles Gilbert Scott (Liverpool cathedral) and Ralph Adams Cram (1863–1942; West Point Military academy and the cathedral of St. John the Divine, New York city) essayed modern versions of Gothic architecture, which became especially popular for colleges, churches and schools that claimed English cultural heritages. Bertram Goodhue (1869–1924), a talented designer in Cram's firm, gave the Gothic Revival St. Thomas' church in New York city convincing elements. A patron of Christian-humanistic education, Andrew Fleming West hired Cram to design the graduate college at Princeton (1913) because he wanted a setting similar to the medieval quadrangles of Oxford and Cambridge.

**1. Art Nouveau.**—Such departures from classicism failed to satisfy men who wanted a totally new architecture. *Art nouveau* (*q.v.*) was the general title for a highly varied movement toward modernism that had international representation. In France bizarre forms appeared in the iron, masonry and concrete structures of Hector Guimard (Humbert des Romans and Métro stations, Paris, *c.* 1900) and Anatole de Baudot (St. Jean l'Evangéliste, Montmartre, 1894–1904). Georges Seurat's "Sunday Afternoon on the Isle of Grande Jatte" begun 1884 had an architectural counterpart in the Dufayel store's interiors at Paris. In Belgium there were Baron Victor Horta's floral, tendrilous ornament at his house at 12 Rue de Turin, Brussels (1893), and an exposition of fine spaces and undulating enclosure in his Maison du Peuple in Brussels (completed 1897). In the U.S. *art nouveau* arrived with Louis Comfort Tiffany; in Italy furniture by A. Charpentier and C. Bugatti was exhibited an international exposition; in Scotland A. H. Mackmurdo and Charles Rennie Mackintosh expressed the new movement in buildings like Mackintosh's art school at Glasgow (1898–99). Even in Spain a representative belatedly developed in Antonio Gaudí (1852–1926), whose sculptural, fungus-like apartment house, Casa Milá, belied the structural experiments and spatial drama of his "Parc Güell" and the enigmatic church of the Holy Family, all at Barcelona. Like other *art nouveau* work, Gaudí's buildings were amazingly personal, gaining their effect through bizarre form and ornament and showing no way past the tangle of competing styles.

**2. The Chicago School.**—What was needed was a major endeavour in regard to the most important new type of building of the modern age, the large office building. The office building was made necessary by the concentration of markets, banks, railroad terminals and warehouses in small sections of growing cities, and it pushed skyward as a result of the attempt to get maximum income from expensive urban properties, the desire for the commercial prestige of tall emblems and the need of businesses for mutual proximity in the days before rapid electronic communication. The safe, fast elevator removed the major prejudice against height. Designed by traditionalist architects, the tall buildings stretched masonry construction to its limits; they frequently resembled towers comprised of smaller buildings stacked one on another, as in Hunt's Tribune building at New York (1874). The structural problem was solved at Chicago in 1884–85, when an engineer, William Le Baron Jenney, developed a metal skeleton of cast-iron columns, sheathed in masonry, and wrought-iron beams, carrying the masonry walls and windows at each floor level. Technically innovative, the building retained masonry side walls, and its elevations were disunified and inept.

Inspired by Viollet-le-Duc's rationalism, Chicago architects sought a better aesthetic expression of the metal frame, but even the talented John W. Root (1850–91), working with Daniel Burnham, failed to achieve it in the Ashland block (completed 1892), and lesser designers, such as William Holabird and Martin Roche in their Tacoma building (1887–88), also missed their chance. Even the great Louis Sullivan (1856–1924) was not successful in his early buildings such as the Ryerson (1884); covering them with gross, somewhat *art nouveau* ornament, he first accentuated the vertical columns and then the horizontal beams, in a covert admission of failure. At his best, as in his Auditorium theatre and hotel (1886–90), Sullivan treaded Richardson's path toward unified Romanesque forms. The Marshall Field warehouse showed Sullivan the way toward a theme for the skyscraper, which he first stated with assurance in the Wainwright building at St. Louis (1890). Brick piers mark each steel column and half module to create a rhythm of tall narrow bays punctuated by recessed spandrels, terminating at the roofline. It was a major, if lonely, triumph for the Beaux-Arts composition Sullivan learned at Paris. But one successful building hardly constituted a new national style. In spite of his eulogy to Whitman's nationalism, his paeans to Darwin's principles of organic growth and his protestations about a new architecture, Sullivan willingly joined other Chicagoans in helping the New York architects, Hunt and Charles Follen McKim (1847–1909), plan the World's Columbian exposition at Chicago in 1893.

A dazzling spectacle of monumental, classical architecture, the fair's midway caught the fancy of Americans who saw in its great axes, lagoons, sculpture, white buildings and large plazas an answer to the dreary urban environment of their home towns. Similar schemes were supported in their cities; some of them were designed by the fair's principal planner, Daniel Burnham, who brought the "great white city" to Cleveland, Washington, New York and San Francisco. The civic spaces of the Place de la Concorde at Paris and the squares at Nancy were emulated. There were gardens and fountains that dimly reflected those at Versailles, and their grandeur sometimes prompted a later generation to disapprove of them as symbols of callous indifference to the social and economic causes of the metropolitan cancer. Still, the best parts of many U.S. cities are as spacious as they are because of the city beautiful movement. Its most popular architect was McKim, whose Public library in Boston's Copley square (1888–95) made a dignified classical counterpart to Richardson's Trinity church. His plan for Columbia university (1895) carried the classical Beaux-Arts image into educational architecture, and for Rhode Island's government he built a classical state capitol at Providence (1895–1902). McKim provided Pierpont Morgan with an exquisite library in New York city (1906) and adapted the baths of Caracalla for the Pennsylvania railroad station there (1906–10). All of these were reliable buildings, grand in conception and competent in detail. Similar buildings appeared in many lands, perhaps because they were so universalized, dependable and unoriginal; often they were the marks of imperialism, as in the case of those built by the French in north Africa, the English in China and India and the Americans in the Philippines.

The ferment in Chicago was neither halted nor marred by classicism's transcontinental popularity. Burnham's firm went on to produce Chicago's Reliance building (1890–95), an excellent office building with logically ordered spaces enclosed by faceted walls of glass and a steel skeleton covered by terra-cotta panels. Sullivan found his best expression of the skyscraper in Buffalo's Prudential building (1894–1905) and developed the theory for it in an essay published in *Lippincott's Magazine* (1896). That theory received even more dramatic expression in the Schlesinger-Mayer store (later Carson Pirie Scott) in Chicago (1899–1904), in which the towered corner marked the climax of the logic of the steel frame

and the entrance was made inviting with rich, naturalistic ornament. At the very end of the 19th century the important emblem of modern commerce thus received an appropriate form: its structure was made of steel, its spaces were planned efficiently, its elevations were expressive of the skeleton and its scale was marked by the fenestration and ornament. Such designs offered clients an opportunity to build well in a style that expressed its time.

## III. THE 20TH CENTURY

### A. From 1900 to 1930

The channels opened by 19th-century engineers like Eiffel, theorists like Morris and movements like *art nouveau* and the Chicago school enabled architects to move quickly toward a refined new architecture for the 20th century. In general, modernism revealed two main tendencies: a strong insistence upon mechanical functionalism, which resulted in a machine aesthetic for architecture; and an organic point of view, which emphasized architectural themes derived from landscape, function and materials. Unfortunately, neither point of view gained more than sporadic allegiance. Most buildings, in an age when only a small percentage were actually designed by architects, were still in 19th-century historical styles. The locus for creative architecture in the U.S. remained the middle west. Californians such as the brothers Greene and the Gills struck occasional regional and modern notes in the west; Bernard Maybeck (1862–1957) ran an eclectic course. Roman in his Palace of the Fine Arts at San Francisco (1915), Gothic and romantic in his First Church of Christ Scientist at Berkeley (1910–12) and somewhat freer in his houses. The Chicago school was more seminal for modern architecture and its members, such as William G. Purcell and G. G. Elmslie, fanned outward. William Drummond moved to the area south of Chicago. Louis Sullivan was called to Grinnell and Cedar Rapids, Ia., and to Owatonna, Minn., to design banks.

**1. Frank Lloyd Wright.**—The greatest of all the Chicago architects was Frank Lloyd Wright (1869–1959). His "prairie architecture" expressed its site, region, structure and materials and avoided all historical reminiscences; beginning with its plan and a distinctive spatial theme, each building burgeoned to its exterior sculptural form. Starting from Richardson's rustic, shingle houses and making free use of Beaux-Arts composition during the '80s and '90s, while he was in Sullivan's office, Wright developed his "prairie house" for the Winslows at River Forest, Ill. (1895), made it more elaborate in the Coonley house at Riverside, Ill. (1908), and, ultimately, realized in it the flowing volumes of space defined by sculptural masses and horizontal planes, of his Robie house at Chicago (1909). Meanwhile, he scored a triumph with his administration building for the Larkin company at Buffalo in 1904, which grouped offices around a central skylighted court, sealed them hermetically against their smoky environs and offered amenities in circulation, air conditioning, fire protection and plumbing. In its blocky fire towers, sequences of piers and recessed spandrels were coupled together in a composition that foretold the handsome industrial architecture of the future.

Reactionaries saw little merit in Wright's work. Critics such as Russell Sturgis thought it was at best rational but awkward and praised instead Burnham's Flatiron building and Napoleon Le Brun's Metropolitan Tower, the distorted classicism of which still pleased New York's clients. Ironically, technological progress negated the Chicago school's successes in the rational expression of the steel frame. Artificial lighting, ventilation and communication compensated for the lack of an efficient plan or large, functional windows. Freed from strict accountability to practicality and logic, the skyscraper architect could dress the skeletal frame any way he or his client chose. A distinctive dress was an advertisement, and the Woolworth company, recognizing this, commissioned Cass Gilbert in 1913 to design a Gothic tower for them in New York city; its flamboyant summit was illuminated at night as a 24-hour advertisement.

**2. Developments in Europe.**—In England and the Netherlands, too, there were conservatives. In London the Beaux-Arts-Georgian War Office at Whitehall was completed in 1907, and Liverpool paid its respects to medieval times with the cathedral begun in 1903. There were also presages of change in the works of the Englishman Voysey and the Netherlands' Berlage. Berlage visited Wright and returned to show younger architects, such as Dudok, the way to handle brick simply in buildings that had regional character.

Germany and Austria moved more quickly and radically. A German architect, Theodor Fischer, inspired by Schinkel's precedent, attempted innovations, with only slight Romanesque and classical references, in his Garnisonkirche at Ulm (1905–11), and Otto Wagner, an Austrian, combined academic geometry with *art nouveau* decoration in his railroad station at Vienna (1894–97), which was followed by his simpler chapel for the cemetery of a sanatorium near Vienna (1904–07). Wagner's pupils broke free of his classicism and formed the Secessionists. The group included Joseph Olbrich (1867–1908), who joined the art colony at Darmstadt, Ger., where his houses and exhibition gallery of about 1905 were boxlike, severe buildings. Joseph Hoffmann left Wagner to found the Wiener Werkstätte, an arts and crafts movement; his best work, the Stoclet house at Brussels (1911), was a Cubist, asymmetrical composition in which white planes were defined at the edges by gilt lines. The Austrian Adolf Loos (1870–1933) opposed the use of any ornament and was determined to obtain quality in compositions of bald, functional blocks. Peter Behrens, having had contact with Olbrich at Darmstadt and with Hoffmann at Vienna, was in 1907 appointed engineer in charge of the German electrical trust (A.E.G.), for which he designed a turbine factory (1909) at Berlin, a direct expression of industry.

Behrens strongly affected three great architects who worked in his office: Walter Gropius, Le Corbusier (Charles Edouard Jeanneret) and Ludwig Mies van der Rohe. Gropius' Werkbund exposition building at the Cologne exhibition (1914) was a model factory building in which vigorous forms were enclosed by masonry and glass; its effect was gained by its use of steel frames, its strong silhouette and the logic of its plan. There were no historical influences, nor were there any expressions of local landscape, traditions or materials. The building was mechanistic; its beauty derived from the adaption of form to purpose.

A less rigorous modernism appeared in Scandinavia, particularly where, as in Sweden, handcrafts survived in furniture and building construction. Regional and national traditions kept history alive, and new architecture seldom revealed the doctrinaire avoidance of precedent or the blind adoration of the machine that harshened German contributions. The charm of Ragnar Östberg's town hall at Stockholm, a programmatic composition, lay in its cloistered spaces, brick walls and ornamental decoration, as well as in its picturesque towers, minarets and colonnades, all of which were simplified versions of earlier themes in Swedish building. Somewhat similar works, though more influenced by Mackintosh, appeared in Finland, as in Eliel Saarinen's railroad station at Helsinki (1910–14), which utilized traditional masonry in strong simple forms and showed the Scandinavians' aversion to anything as mechanistic as Gropius' factories.

France remained ambivalent. Guimard and De Baudot had essayed idiosyncratic versions of *art nouveau*, and other designers followed Henry van de Velde, a Belgian, who after 1895 stimulated a vogue for *art nouveau* in the minor arts which occasionally manifested itself in buildings, such as the house at 4 Avenue Jena, Paris. The dominant tradition, however, stemmed from the Beaux-Arts. Even the Théâtre des Champs Élysées (1911–13) by Van de Velde and Auguste Perret (1874–1954) was an academic composition, though its ferroconcrete frame sheltered three separate auditoriums and a store.

On his own, Perret achieved a frank exposition of reinforced concrete skeletons and developed spaces within temporary partitions, as at his apartment house on the Rue Franklin, Paris, which in 1902 and 1903 marked a major advance from the Beaux-Arts tradition. Still the École's Grand Prix went to traditional designs, such as that awarded for an Institut de France in 1921, a symmetrical, classical scheme. One winner, however, Tony Garnier (1869–1948), caught the modern currents in materials, structure and composition when he evolved his masterful plan for a *cité industrielle* (1901–04), published in 1917, in which reinforced

concrete was to be used to create a city of modern buildings. With insight, Garnier developed a comprehensive scheme for residential neighbourhoods, transportation terminals, schools and industrial centres, and his plan became a major and influential scheme for a modern metropolis. Garnier received no mandate to build such a city, but his pavilion for Lyons at the International Exposition of Decorative Arts at Paris (1925) and his town hall at Boulogne-Billancourt (*c.* 1935) recalled the promise he had shown, though they were not so innovative and masterful as might have been expected.

For about 15 years after World War I advocates of Expressionism achieved modern, personal, highly sculptural forms (*e.g.*, Eric Mendelsohn in his factories and Einstein tower at Potsdam). Rudolf Schwarz, D. Bohm and O. Bartning made important modern churches; but there was a return to more restraint in religious architecture as in Notre Dame de Le Raincy by Perret (1922–23).

Paris became the stronghold of the advocates of a new vision of space. Cubism, which Georges Braque and Pablo Picasso developed in 1908 from suggestions in Paul Cezanne's paintings and in primitive African sculpture. Forms were dismembered into their faceted components; angular forms, interpenetrated planes, transparencies and diverse impressions were recorded as though seen simultaneously. Soon, reflections of Cubism appeared in architecture. Interior spaces were defined by thin, discontinuous planes and glass walls; supports were reduced to slender metal columns, machine finished and without ornamentation; and Cubistic voids and masses were arranged programmatically in asymmetric compositions.

Membership in the movement was international. In the Netherlands, Piet Mondrian and Theo van Doesburg began their magazine, *de Stijl*, in 1917. Doesburg's work for the Bauhaus art school at Weimar, Ger., brought his influence to bear upon Gropius and Mies, whose plans for houses sometimes bore a marked similarity to Doesburg's Cubistic paintings. Meanwhile, the Dutch architect J. J. P. Oud collaborated with Doesburg for a time and vigorously proclaimed the new style in houses he built at Rotterdam (after 1918), Hook of Holland (1924–27) and Stuttgart (1927). Cubism, like any other style, might have faltered and fallen into a merely decorative cliché, as at the Paris exposition of 1925, but three great architects prevented its demise.

**3. Le Corbusier.**—The Swiss-French architect Le Corbusier gave the new architecture a firm foundation by writing the strong theoretical statement, *Vers une architecture*, published in 1923. It revealed a world of new forms—not classical capitals and Gothic arches but ships, turbines, grain elevators, airplanes and machine products, which Le Corbusier said, were indexes to 20th-century imagination. His love of machines being combined with a belief in communal authority as the best means of accomplishing social reform, Le Corbusier directed his attention toward the problems of housing and urban patterns. An architectural attack, using standardized building components and mass production, was required. His sociological and formal ideas appeared in a Cubist project for Domino housing (1916), and his aesthetic preferences led him after World War I to develop an extreme version of Cubist painting he and Amédée Ozenfant called Purism. Returning to architecture in 1921, he designed a villa at Vaucresson (1922), whose abstract planes and strip windows revealed his desire to "arrive at the house machine . . . standardized houses with standardized furniture." In 1922 he also brought forth his project for a skyscraper city of 3,000,000 people in which tall office and apartment buildings would stand in broad open plazas and parks with the Cubist spaces between them defined by low row housing.

Much of his works thereafter—his Voisin city plan, his Pavillon de L'Esprit Nouveau at the Paris exposition of 1925, his exhibit of workers' apartments at the Werkbund exposition at Stuttgart (1927) and his influential but unexecuted submittal to the League of Nations competition—were footnotes to that dream of a new city. The villa, "Les Terrasses," at Garches (1927) was a lively play of spatial parallelepipeds ruled by horizontal planes, but his style seemed to culminate in the most famous of his houses, the Villa Savoye at Poissy (1928–30). The building's principal block was raised one story above the ground on *pilotis* (heavy, reinforced-concrete columns), floors were cantilevered to permit long strip windows and space was molded plastically and made to flow horizontally, vertically and diagonally until, on the topmost terrace, the whole composition ended in a cadenza of rounded, terminating spaces. Gaining greater facility in manipulating flowing spaces, Le Corbusier designed the dormitory for Swiss students at the Cité Universitaire (1930–32) in Paris. This was a major public building, and it suggested that an exciting new architecture might soon serve education.

**4. Gropius.**—In Germany Gropius moved in a more mechanistic direction. After completing his model factory at Cologne in 1914, he succeeded Van de Velde as director of the ducal Arts and Crafts school at Weimar in 1919. Later called the Bauhaus (*q.v.*), it became the most important centre of modern design until the Nazis closed it in 1933. While he was at Weimar, Gropius developed a firm philosophy about architecture and education, which he announced in 1923. The aim of the visual arts, he said, is to create a complete, homogeneous physical environment in which all the arts have their place. Architects, sculptors, furniture makers and painters must learn practical crafts and obtain knowledge of tools, materials and form; they must become acquainted with the machine and attempt to use it in solving the social problems of an industrial society. At the Bauhaus, aesthetic investigations into space, colour, construction and elementary form were flavoured by Cubism and Constructivism. Moving the school to Dessau in 1925, Gropius designed the pioneering new Bauhaus (1925–26) in which steel frames and glass walls provided workshops within severely Cubistic buildings. Gropius assembled a staff of modern teachers, including Laszlo Moholy-Nagy, Wassily Kandinsky, Paul Klee, Marcel Breuer and Adolf Meyer, whose projects, such as the 116 standardized units at the experimental housing at Dessau-Theorten (1926–28), bore a highly machined, depersonalized appearance.

**5. Mies van der Rohe.**—Gropius was succeeded at the Bauhaus in 1930 by Mies, whose training as a mason was supplemented by the engineering experience he gained in the office of Behrens (1908–11). Influenced by Doesburg's *de Stijl*, Mies's natural elegance and precise orderliness soon revealed themselves in projects for a brick country house and a glazed, cantilevered concrete-slab office building (1920–22). He directed the Weissenhofsiedlung at Stuttgart (1927), contributing the design for an apartment house. Such practical problems failed to show his talent, which was not fully known until he designed the German pavilion for the International exposition at Barcelona in 1929. The continuous spaces partitioned with thin marble planes and chromed steel columns drew international applause. His Tugendhat house at Brno, Czech. (1930), along with Le Corbusier's Villa Savoye, epitomized the modern domestic setting at its best.

### B. From 1930 to World War II

**1. The Spread of Modern Styles.**—After 1930 the modern movement spread through Europe. In Switzerland Robert Maillart's experiments with reinforced concrete attained great grace in his Salginatobel bridge (1930) and Cement hall at Zürich (1939). Finland's Alvar Aalto won a competition for the library at Viipuri (now Vyborg, U.S.S.R.) in 1927 with a building of glass walls, flat roof and round skylights (completed 1934; now destroyed); but he retained a sympathy for wood and picturesque planning, which were evident in his house at Mairea (1938–39), the factory and housing at Sunila (1937–39), his building at the New York World's fair (1939) and M.I.T.'s Baker dormitory. Aalto and other Scandinavians gained a following among those whom severe German modernism repelled. Sweden's Sven Markelius and Gunnar Asplund (crematorium, Forest cemetery, Stockholm, 1938–40) and Denmark's Kay Fisker, C. F. Möller and Arne Jacobsen also brought regional character into their modern work. In the Netherlands J. A. Brinkman and L. C. van der Vlugt, at the Van Nelle tobacco factory in Rotterdam (1929–30), aimed at more mechanistic, universal form. In England, German refugees, alone or with English designers, inaugurated a radical modernism that culminated during the '50s in school architecture and the Royal Festival hall, London (opened 1951, R. H. Matthew and J. L. Martin).

As regards industrial architecture, notable successes were achieved in the clothing factory at Congleton, Cheshire (1948), by Rudolf Frankel and the rubber factory at Brynmawr, south Wales (1951), by the Architects' Co-operative Partnership. In housing, the Churchill Gardens at Pimlico, London (1952), by Philip Powell and Hidalgo Moya and the Lawn flats at Harlow New Town, Essex (1951), by Frederick Gibberd, were notable contributions.

Russia in the period after the Revolution at first encouraged modern art and several architects, notably Bruno Taut, looked to the new government for a sociological program. V. Tatlin's project for a monument to the third international (1920) was a machine in which the various sections (comprising legislative houses and offices) would rotate within an exposed steel armature. A workers' club in Moscow (1929) had a plan resembling half a gear, and the Ministry of Central Economic Planning (1928–32), designed by Le Corbusier, was a glass-filled slab. By the time it was completed, the building was subjected to official disfavour, as Stalin's government adopted classical monuments, such as B. M. Iofan's winning design for the Palace of the Soviets (1931), which was intended to pile classical colonnades to a height of 1,365 ft. and have a colossal statue of Lenin at its summit. With its gigantic Corinthian columns, the building for the central committee of the Communist party at Kiev (1937) showed an overbearing scale and wasteful pomposity. There were also evidences of regionalism where folk motifs appeared, as in the tentlike pavilion of Uzbekistan at the Moscow exposition of 1939. After World War II the classical, stepped skyscraper was the form used for Moscow university, which Russian architects admired for its amenities. There were evidences of simplification and mechanization of form in the Russian pavilion at the Brussels exposition of 1958, which showed a modified and more economical classicism. (*See* also RUSSIAN ARCHITECTURE: *The Soviet Period.*)

Mexico and South America broke their bonds to French, Spanish and Portuguese academic design during the '30s. Le Corbusier's influence became strong in Brazil, where Oscar Niemeyer and other architects designed the Corbusier-inspired Ministry of Education and Public Health at Rio de Janeiro (1937–42). Lucio Costa, Félix Candela and Niemeyer were the vanguard of modernism; whole communities, as at Caracas, São Paulo, the University of Mexico and Brasilia during the '50s, were rebuilt. In Mexico there was avid support for modern design in buildings such as the Presidente Juárez housing at Mexico City (1950) by Mario Pani and Salvador Ortega. In Colombia, after World War II, enormous strides were made in thin-shelled reinforced-concrete construction. In Brazil dramatic complexes were erected from concrete (*e.g.*, the school and gymnasium at Pedregulho housing, Rio de Janeiro, 1953, Affonso Eduardo Reidy).

Until about 1935 leading architects and architectural schools in the United States tended to ignore modernism. Industry showed some inclination to respect function, materials and engineering, as was evident in Joseph Leland's glazed, skeletal buildings for the Pressed Steel company at Worcester, Mass. (1930). The National Cash Register, United States Shoe Machinery, National Biscuit, Sears, Roebuck and various automobile companies, such as Ford, sponsored functional architecture. Occasionally a traditional architect produced an innovation such as Willis Polk's Halldie building at San Francisco. With the aid of Ernest Wilby, the engineering firm of Albert Kahn created a work of architectural merit in Detroit's Continental Motors factory of about 1918.

**2. Residences by Wright.**—During most of this period, America's foremost architectural genius, Frank Lloyd Wright, was ignored by all except a select following. The single figure who gave international distinction to American 20th-century architecture was for the most part neglected by major universities, church organizations and industries. His architecture remained the cherished property of personal clients, such as Aline Barnsdall for whom Wright designed the "Hollyhock house" at Hollywood, Calif. (1917–20). His *Autobiography* recorded his frustrations in gaining acceptance for organic architecture. The first edition summarized the chief features of that architecture: a reduction of the number of rooms to a minimum and the definition of them by point supports; the close association of buildings to their sites by means of extended and emphasized planes parallel to the ground; the free flow of space, unencumbered by boxlike enclosures; harmony of all openings with each other and with human scale; the exploitation of the nature of a material, both in its surface manifestations and its structure; the incorporation of mechanical equipment and furniture as organic parts of structure; and the elimination of applied decoration. There were also four new properties: transparency, which was obtained through the use of glass; density or plasticity of mass, achieved through the use of steel in tension as in reinforced concrete; naturalism, or the expression of materials; and integration, in which all ornamental features were natural by-products of manufacture and assembly.

The Millard house at Pasadena, Calif. (1923), exemplified many of these principles; its concrete-block walls were cast with decorative patterns. Taliesin East, Wright's house at Spring Green, Wis., went through a series of major rebuildings (1911, 1914, 1915 and 1925), and each fitted the site beautifully; local stone, gabled roofs and outdoor gardens reflected the themes of the countryside. A period of withdrawal at Taliesin afforded Wright several years of intensive reflection, from which he emerged with fabulous drawings for the Doheny ranch in California (1923), a skyscraper for the National Life Insurance company at Chicago (1924–25) and St. Mark's Tower, New York city (1929). The last was to have been an 18-story apartment house comprising a concrete stem from which four arms branched outward to form the side walls of apartments cantilevered from the stem to an exterior glass wall. Unexecuted, like most of Wright's most exciting projects, St. Mark's Tower testified to his revolutionary thinking about skyscraper architecture. His ideas gained a wide hearing in 1931 when he published the Kahn lectures he delivered at Princeton in 1930. In keeping with the needs of the United States during the depression, Wright turned his attention to the low-cost house, designing a "Usonian house" for Herbert Jacobs at Madison, Wis. (1937) and a quadruple house, "the sun houses," at Ardmore, Pa. (1939). These exemplified the residences he intended for his ideal communities, such as rural, decentralized Broadacre City (1936), which was Wright's answer to European schemes for skyscraper cities.

At about the same time, Wright sketched four masterpieces: "Fallingwater" (1936–35), the daringly cantilevered week-end house of Edgar Kaufmann; the administration building of the Johnson Wax company, in which brick cylinders and planes develop a series of echoing spaces, culminating in the forest of graceful "mushroom" columns in the main hall; the Johnson house at Racine (1937), aptly called "Wingspread"; and Taliesin West at Paradise Valley, near Phoenix, Ariz. (begun 1938), where rough, angular walls and roofs echo the desert valley and surrounding mountains. With increasing sensitivity to local terrain and native forms and materials, Wright stated more complex spatial and structural themes than European modernists who seldom attempted either extreme programmatic plans or organic adaptation of form to a particular environment. Eventually, Wright himself developed a more universal geometry, as he revealed in the sculptural Guggenheim Museum of Non-Objective Art at New York city (1955–59).

**3. Other Works of the Period.**—In terms of volume, Wright's work was inconsequential. During prosperous days, commissions for country clubs and splendid estates were given to more eclectic architects. Henry Ford entertained the idea of asking Wright to design his house, but ultimately went elsewhere. With the aid of technology, Spanish estates were built on the shores of Florida, French farmhouses in Philadelphia, Georgian and colonial homes in New England and pueblos in the southwest. Georgia revived its ante-bellum architecture, and Santa Barbara, Calif., which was destroyed by an earthquake in 1925, was quickly rebuilt as a Spanish mission. The Georgian Revival style threatened to supplant regionalism as architects worked with one eye on the "White Pine Series of Architectural Monographs." Gothic was nearly universal for churches; often archaeological, as in Cram's Swedenborgian Cathedral at Bryn Athyn, Pa. (1913–28), it was only occasionally creative, as in Goodhue's St. Bartholomew's, New York city, and H. Van Buren Magonigle's First Plymouth Congregational, Lincoln, Neb. University architecture invariably failed to

reflect forward-looking educational practices; Harvard's business school was housed in Georgian Revival buildings (1925), and Yale erected Gothic quadrangles for its residential colleges (begun 1929). M.I.T. moved to a new "Roman" campus in 1916, and at the universities of Colorado and California tales were invented to justify "regional" buildings. Expositions flaunted eclectic designs, usually Roman, as at the Panama-Pacific, San Francisco (1915), or regional, as was intended by the Spanish at San Diego, Calif. (1915); but modern could also be superficial, as proved by the Century of Progress exhibition at Chicago (1933–34). An illustration of the taste of the period is the Chinese temple incongruously erected as a teahouse on the Belmont estate, Newport, in 1916.

The traditionalists also produced some memorable things in their final hour. John Russell Pope's version of the Mausoleum at Halicarnassus which he built as the Temple of the Scottish Rite at Washington in 1916 and Louis Bourgeois' Bahai temple on the shore of Lake Michigan near Chicago were not defensible by 20th-century architectural standards. Critics like Jacques Greber, Werner Hegemann and Elbert Peets, however, found much that classical taste could admire: the New York Public Library, the Cleveland Museum of Art, the University Club at New York city and the Rockefeller estate at Pocantico Hills, N.Y. Architectural schools continued to put students through a Beaux-Arts curriculum. No school considered itself complete unless it had a French patron; one of them, Pennsylvania's Paul Cret, designed superb classical buildings, such as the Pan American Union building at Washington (1908–10), the Public Library at Indianapolis (dedicated 1917) and the Institute of Arts at Detroit (1927). Many architects achieved perfection of form, as in Bacon's Lincoln memorial at Washington, and even where there was more bombast than was suitable, as in Gilbert's Supreme Court building at Washington (1935) or his Public Library at Detroit (1921), the work was seldom ugly, and its durable materials, rational plans and extravagant spaciousness suited the public need for dignity and grandeur. Only an occasional designer showed an aptitude for originality without flagrantly violating tradition, and of those who did, Magonigle in his Liberty memorial at Kansas City, Mo. (1928), and Goodhue in the capitol in Lincoln, Neb. (begun 1922), and National Academy of Sciences at Washington (1924) showed, along with Cret, a time-honoured way to create an architecture for the 20th century.

**4. Office Buildings.**—The emblem of business, the office building, continued to suffer from demands for unique, distinctive towers. Harvey Wiley Corbett, a New York architect, admitted that publicity was the ruling motivation. Sometimes a business with nation-wide suboffices developed a corporate iconography; Sears Roebuck, Bell Telephone, Howard Johnson and the various competing gasoline companies were recognizable instantly. The Gothic skyscraper, popularized by Gilbert's Woolworth building, was used in Corbett's Bush Terminal building at New York city (1917) and Raymond Hood's winning entry to the *Chicago Tribune* competition (1922). Some buildings gained attention through their classical ornament (Le Brun's Metropolitan Tower); others, such as Charles Platt's Hanna building and Leader News building in Cleveland (*c.* 1922), were Renaissance palaces. About 1920 some architects developed simple cubical forms, and the stepped ziggurat was popularized by renderers, notably Hugh Ferriss, and artists like Georgia O'Keefe, John Marin and Charles Sheeler. This soaring and jagged form received legal support from the New York zoning law of 1916 and economic justification from the fact that, in order to obtain rentable, peripheral office space in the upper floors where the banks of elevators diminished, whole increments of office space had to be omitted. These cubical envelopes were not without ornament at their crests, as in Hood's American Radiator building in New York city (1924–25), suitably described as "one huge cinder incandescent at the top." Such decoration might be chic, as in New York city's Barclay-Vesey or Telephone building, where Ralph Walker recreated the gay interiors of the Paris exposition of 1925. In San Francisco, Miller, Pflueger & Cantin used Chinese ornament to enliven their Telephone building (1926). Paradoxically, one archaeological find led to simpler buildings when, about 1930, Mayan pyramids inspired Timothy Pflueger in his work on the 250 Sutter building in San Francisco. Cliff like blocks arose in Chicago, the Daily News and Palmolive buildings (1929) being the best examples; New York city acquired a straightforward expression of tall vertical piers and setback cubical masses in the Daily News building (1930) by the versatile Hood, who had run the course from Gothic to modern form. Philadelphia's bank and office building of the Pennsylvania Savings Fund society (1931) by George Howe and William Lescaze, a Swiss architect, gave the skyscraper its first thoroughly 20th-century form, and Hood, again, produced a counterpart in New York city, the McGraw Hill building (1932). Few of these, including the Empire State building (1929–31), did anything to solve urban density and transportation problems; indeed they intensified them. Rockefeller centre, however, begun in 1931, was, with its space for pedestrians within a complex of slablike skyscrapers, outstanding and too seldom copied.

**5. American Modernism.**—As the example of Rockefeller centre indicates, there was a move toward simple form, which was presaged by the architecture of the TVA. European modernism gained a firm following in the United States as some of its best practitioners emigrated there. Eliel Saarinen, who won second prize in the *Chicago Tribune* competition, gained the acclaim of Sullivan and other architects and settled at Bloomfield Hills, Mich., where he established a school of architecture at the Cranbrook academy. He designed its new buildings, gradually freeing himself from historical reminiscences. He remained sensitive to the role of art in architecture, best revealed by his use of Carl Milles' sculpture. Together with his son, Eero, Saarinen designed the Kleinhans Music hall at Buffalo (1940–41). Richard Neutra, after a visit in 1923, established a practice in California, recalled by the Lovell house at Los Angeles (1929). An exhibit of modern architecture in the Museum of Modern Art, New York city, in 1932, recorded in the book *International Exhibition: Modern Architecture* by Henry Russell Hitchcock, familiarized Americans with the international style. After 1933, as modernists fled Russia, Germany and Italy, the United States received Gropius, Breuer and Mies. Gropius was brought to Harvard by the newly appointed dean of the architectural school, Joseph Hudnut, and established an educational focus recalling the Bauhaus. In association with Breuer, Gropius introduced modern houses to Lincoln, Mass., and formed a group, the Architects' Collaborative, whose members designed the thoroughly modern Harvard Graduate centre. Mies became director of architecture at the Illinois Institute of Technology, Chicago, in 1938 and designed its new campus.

Not all the immigrants remained in the U.S. Aalto, whose work first appeared on the American scene in the Finnish pavilion at the New York World's fair and again in Baker dormitory, returned to Finland. The European who might have contributed most was Le Corbusier. The United Nations buildings at New York city, for which he was a member of a ten-man commission headed by New York architect Wallace Harrison, is a token of the new forms he might have suggested for U.S. cities. His plan for rebuilding St Dié (1945) was the inspiration for many city-planning proposals made after mid-century.

Beginning with private houses by Hood, Lescaze, Edward Stone, Neutra, Gropius and Breuer during the '30s, American modernism came to be used for all types of buildings and gradually supplanted sentimental historicism. Programmatic school architecture accompanied progressive education; Perkins & Will, the Saarinens, John Lyon Reid, Donald Barthelme, the Architects' Collaborative and many others made attractive pavilion, "finger," campus and "cluster" plans. In church architecture, Pietro Belluschi won converts to modernism with his brick and wood churches in Oregon and Boston; Eliel Saarinen's churches at Columbus, Ind., and Minneapolis were incomparable.

### C. After World War II

After World War II, big industry turned to modern architects for distinctive emblems of quality. The Connecticut General Life Insurance company hired one of the largest and best modern firms, Skidmore, Owings & Merrill, to design their new decentralized headquarters outside Hartford, Conn. (1955–57). Lever Brothers

turned to the same firm for New York's Lever house (1952), in which the parklike plaza, glazed curtain walls and thin aluminum mullions realized the dreams of Mies and others in the 1920s of freestanding crystalline shafts. The General Motors corporation's Technical centre at Detroit was compared with Versailles in its extent, grandeur and rigorous conformity to an aesthetic the Mies-like forms of Eero Saarinen. The tower for the Aluminum Company of America at Pittsburgh advertised its own product (Harrison & Abramovitz, 1954). Skidmore, Owings & Merrill also designed the Inland Steel building in Chicago in 1955. Perhaps the most chaste of all was the Seagram building at New York city, an elegant prism of bronzed skeleton and amber-lighted offices, designed by two of the purest architects, Mies and Philip Johnson. Wright alone avoided the rectilinear geometry. In 1955–59 he saw his Price Tower rise at Bartlesville, Okla., a richly faceted concrete and copper fulfillment of the St. Mark's Tower he designed more than 25 years earlier.

About 1952 there was a significant shift within modernism from what had come to be called "functionalism" toward a monumental formalism. Presaged by Wright's work at the Johnson Wax company, there was increasing interest in the convolutions of highly plastic, sculptural masses and spaces. Wright's Guggenheim museum was a manifestation of it. Those who had focused their attention on the rectilinear portions of Le Corbusier's Villa Savoye and apartment house (Unité d'Habitation) at Marseilles tended to ignore the plastic sculpture on the roofs of those buildings; to such people, Le Corbusier's building at Chandigarh, India (begun 1950), and the cavernous space in the lyrical Notre Dame du Haut seemed to be sports. Pier Luigi Nervi in Italy gave structural integrity to the complex curves and intricate geometry of reinforced-concrete structures, such as Bologna's tobacco factory (1949), Orbetello's hangar's (begun 1938) and Turin's exposition hall (1950). The Mexican Candela, the Spaniard Eduardo Torroja and the American Frederick Severud followed his lead. Essentially, each attempted to create an umbrella roof whose interior space could be subdivided as required. Mies constructed rectilinear versions of such a space in Crown hall at I.I.T. (1956) and in his Farnsworth house at Plano, Ill. (1952), while Johnson allowed a single functional unit, the brick cylinder utility stack, to protrude from the precise glass house he built for himself at New Canaan, Conn.

Other designers used curvilinear structural geometry, best indicated by Matthew Nowicki's Stock pavilion at Raleigh, N.C., in which two tilted parabolic arches, supported by columns, and a stretched-skin roof enclose a colossal space devoid of interior supports. In 1949 Nowicki challenged Sullivan's precept, form follows function, with another, form follows form, a dictum that freed architecture from programmatic expression. The mechanistically functional Harvard Graduate centre, in spite of its superior site planning, seemed a thing of the past when, in 1955, Eero Saarinen completed a spherical triangle for M.I.T.'s Kresge auditorium. Stone's U.S. pavilion at the Brussels fair, Hugh Stubbins' Congress hall at Berlin (1957) and the new terminals at the Idlewild International airport, New York (1958–59), were outstanding examples of the monumental, single-form buildings designed by leading architects. In their search for unique silhouettes, some designers invented bizarre geometric shapes, such as those in Eero Saarinen's hockey rink at Yale (1958) and Harrison & Abramovitz' Presbyterian church at Stamford, Conn. (1958). A much more difficult task, that of unifying a modern programmatic building within an old setting, was undertaken by Paul Rudolph in the Art centre at Wellesley college, Wellesley, Mass. (1957–59), but such an approach appeared infrequently; international competitions for the opera house at Sidney, Austr. (1957), and a government centre at Toronto, Ont. (1958), were won by the exponents of monumental design. These posed problems in structural engineering and in scale, but many architects, such as Yamasaki in the McGregor building for Detroit's Wayne university (1958), attempted to make structure become decorative, while the decorative screen, as used by Stone at the U.S. embassy in New Delhi (1957–59), offered a device for wrapping programmatic interiors within a rich pattern of sculptural walls.

Having created buildings that deserved a place in the history of architecture, the modern architect and city planner awaited a mandate to give shape to the modern social unit, the metropolitan-suburban-rural community. All its components were available and tested: Mies's 850–860 Lake Shore drive, Chicago, suggested what the apartment houses might be; 100 Memorial drive at Cambridge, Mass., by Brown, Rapson, de Mars, *et al.*, and Le Corbusier's Marseilles block showed other versions. Britain's festival and the Brussels fair suggested new kinds of civic and cultural buildings, while Victor Gruen's shopping centres at Minneapolis and Detroit provided humane retail cores for pedestrians. The competitions for the opera house at Sidney and the government centre at Toronto elicited monumental public buildings. Lewis Mumford and Sigfried Giedion described how the modern city should be shaped. Le Corbusier, Eliel Saarinen, José Luis Sert, Wright, Nowicki and City Planners drew clear proposals. Louis Kahn's Mill Creek project in Philadelphia, Boston's Back Bay centre by Belluschi, Gropius and others, the British "New Towns," the reconstructed sections of Rotterdam and Brasília showed what should have been clear by 1940: that modern architecture is a means of creating the environment needed in cities and towns.

**MODERN ART,** a term used to describe outstanding developments in western art since the end of the 19th century. It embraces a wide variety of movements, theories and attitudes whose modernity resides in a common tendency to repudiate past precedents and conventions. Although cumulatively modern art has been revolutionary, it has reflected a contemporaneous and wholesale reorientation of thought and human values.

Nineteenth-century art, no longer in service to church, court or community, had lost its *raison d'être* together with its spirit of collective endeavour, and artists were confronted with the need for new standards and justifications. Also, since the Renaissance painters had devoted their skills to problems of representation and although Impressionism (q.v.) seemed a triumphant vindication, its achievement disclosed that complete submission to the subject conceded nothing either to personal interpretation or to formal qualities of design. Modern painting began as a reaction to the aims and methods of Impressionism. Subsequent developments contained from the decisive influence of Paul Cézanne, Vincent Van Gogh and Paul Gauguin. Cézanne painted the permanent underlying structure of nature; his conception of form as the indispensable element was echoed in Cubism, was discernable in Futurism (q.v.) and found its ultimate expression in abstract art. Van Gogh recorded his highly charged feelings in the presence of nature; the compelling example of his emotional approach was strongly apparent in Expressionism (q.v.). Gauguin used visual themes as the basis of a decorative symbolism; Fauvism (q.v.) derived largely from his exploitation of colour and his deliberate use of shape and contour in design.

In the first quarter of the 20th century, eager, widespread investigations were made into new aesthetic experiences. The art

forms of every age and civilization were studied. Ceaseless experiments were made with media and treatments capable of expressing new concepts. The brilliant colours of Fauvism were extinguished by Cubism. Cubist forces, derived partly from Negro art but mainly from a close analysis of spatial relations and the qualities of different surfaces and materials, exercised a decisive influence on the development of abstract painting and sculpture. A throng of movements represented every shade of emphasis from a moderate desire for change to a violent intention to destroy.

Architecture was in similar confusion. *Art nouveau* attempted to break an enslaving continuity of historical mannerisms, but the application of yet another style solved no architectural problems. An important formative period between the wars, dominated by Le Corbusier (Charles Édouard Jeanneret), by Frank Lloyd Wright and his "organic architecture" and by Walter Gropius and the Bauhaus (*q.v.*), culminated in a drastic, calculated simplification. Ornament was stripped away ruthlessly to reveal the functional structure, newly informed with a refined sense of proportion and rhythm and expressed in new materials and techniques. (*See* also MODERN ARCHITECTURE: *The 20th Century.*)

This development mirrored a modern inclination to purge art of all ambiguities which might conceal its nature or hinder spontaneity of expression. The tendency was exemplified by modern music's anti-Romantic aversion to literary associations, by modern poetry's avoidance of insistent sentiment and rejection of sustained clarity of thought and, in both arts, by the dismantling of the scaffolding of stereotyped forms. Painting, undergoing a similar distillation, became an end in itself, not the imitation of anything else. The artist, solely preoccupied with the discovery and expression of his own personality, painted with the intention of recording his own responses. The door of the objective world was closed, but the inner world of the imagination, even the underworld of the subconscious, offered infinite possibilities for exploration. The deliberate explicitness of Surrealism and later the involuntary techniques of Abstract Expressionism were typical of these investigations. Form and colour, no longer representational, were the elements either of an expression or of a construction. In the next short step, the subject was rejected. Abstract art emerged, and its persistent ubiquity, particularly in its later development as Action Painting, tends to confirm it as the characteristic expression of the modern movement.

The evolution of abstract painting corresponded to architecture's reversion to first principles, but, while modern architecture found some coherence, modern painting continued to be the reflection of unfettered individualism; in its energetic, teeming creativeness, eloquent and significant expressions mingle with those that were obscure, impatient or tentative. Modern art is the sum of its greatest exponents, a record of such outstanding individual artists as Wassily Kandinsky, Henri Matisse, Piet Mondrian, Paul Klee, Pablo Picasso and Jackson Pollock.

**MODERNISM, ROMAN CATHOLIC.** Modernism was a European intellectual movement of the last decade of the 19th and first decade of the 20th century which sought to reinterpret traditional Catholic teaching in the light of 19th-century philosophical, historical and psychological theories. "Modernism" as a technical term of Roman Catholic theology first appeared in the ecclesiastical journal *Ami du clergé* (1898) and quickly gained currency in French and German theological periodicals; it was first used in an official, public, church document in the collective Christmas pastoral letter of the bishops of north Italy in 1905. The term refers both to the intellectual movement and to a loosely knit body of propositions or theses advocated by members of the movement who are called modernists.

On Nov. 18, 1893, Pope Leo XIII, responding to the initial surge of interest in critical biblical studies based upon scientific linguistics and archaeological discoveries, issued the encyclical *Providentissimus Deus* which outlined the norms and attitudes Roman Catholics should adopt in critical exegesis and historical criticism of the Bible. It reaffirmed in clear terms the church's traditional belief in the Bible's inspiration (that the sacred books were written by the inspiration of the Holy Spirit and have God for their author *Spiritu Sancto inspirante conscripti Deum habent auctorem*) and inerrancy. Alfred Firmin Loisy (*q.v.*), French Catholic priest, biblical scholar and teacher at the Institut Catholique in Paris, on expressing disagreement with the encyclical in his periodical *L'Enseignement biblique* was dismissed by church authorities from his teaching post.

Loisy's disagreement with the pope's principles was shared by a group of European intellectuals, among them Baron Friedrich von Hügel and George Tyrrell (*qq.v.*) in England and Giovanni Semeria in Italy. They were dissatisfied with Catholic apologetics, which they thought ignored scientific history and relied too much on metaphysics. They believed that scholastic metaphysics when employed in theology turned the revelation into a narrow-minded dogmatism devoid of religious value. Loisy maintained that humanity possessed an intuitive sense which was ever in the process of evolving less anthropomorphic notions about God. He identified religion and this active evolution of humanity. Faith was the experience of man's beliefs about God and not an intellectual assent to God's revealed Word. The Bible recorded successive stages of this human evolution. It was not inspired by God and not inerrant. Credal formulas were true only for the age that composed them. Each creed and each religion represented a certain level in humanity's development. Catholicism was the highest stage yet reached by humanity, but unless it "opened" its dogmatic structure to the data of scientific history and modern psychology it would be superseded by another religion welling up from man's intuitive sense of the divine. These theories of Loisy were what the periodical *Ami du clergé* called modernism.

In 1901 the conservative theologian Julien Fontaine published a harsh and alarming book, *Les Infiltrations kantiennes et protestantes et le clergé français*, in which he accused the distinguished church historian Pierre Batiffol and the *Revue d'histoire et de littérature religieuses* of advocating principles condemned by *Providentissimus Deus*. Batiffol indignantly answered Fontaine, and two world-renowned scholars, Eugène Portalié and Marie Joseph Lagrange, joined in his defense. The Fontaine incident set a pattern for the orthodox reaction to modernism: Batiffol was not a modernist, but the *Revue d'histoire* had compromised its orthodoxy by printing articles by real modernists; Fontaine's attack on the *Revue* was justified, but his assault on Batiffol was not. Fontaine's successors employed his style of accusation, which confused rather than clarified issues and won sympathy for real modernists in quarters where they and their ideas were unacceptable.

In Nov. 1902 appeared Loisy's *L'Évangile et l'Église*, in which, using the pen name A. Firmin, he advanced his thesis that the burden of Jesus' message was the imminent arrival of an eschatological Kingdom and that when the Kingdom failed to materialize his disciples reinterpreted his teaching and founded the church—contradicting orthodox teaching that Christ founded the church; furthermore, Jesus revealed no real truths about God but gave his fellow men religious symbols to inspire every age. Tyrrell developed the meaning of religious symbolism that same year in *Religion as a Factor of Life*, published under a pseudonym, in which he clarified Loisy's theory by declaring that the symbols are speculatively false but practically true and that knowledge of them is gained not from the teaching of the church but from a religious, personal intuition. For Tyrrell the most important symbol was the resurrection, which signified that "the divine personality of Jesus cannot die"; so great an impact had Jesus made on humanity's intuitive sense of the divine that all future religion must incorporate his ideals. As a literal fact Christ did not rise from the

dead; yet, properly understood, a truly religious man must believe in the resurrection since it is a datum of humanity's intuitive sense of the divine. On Jan. 17, 1903, François Cardinal Richard of Paris condemned Loisy's *L'Évangile et l'Église* without mentioning Tyrrell's book.

Loisy bided his time until Tyrrell, using another pseudonym, published, later in 1903, *The Church and the Future*, in which he declared that the church was not infallible and that her dogmas were not definitive statements of immutable truths but attempts approximating intellectualization of religious symbols such as the resurrection. Once this had appeared, and was not condemned, Loisy, in Oct. 1903, published his *Autour d'un petit livre*, which sought to defend *L'Évangile et l'Église* by restating Tyrrell's position on the mutability of dogma and by putting the source of dogma not in divine revelation but in perfectible human consciousness.

At the request of Cardinal Richard, two theologians, Georges Letourneau and Pierre Bouvier, made a list of 33 propositions based on Loisy's work which the cardinal sent to Rome. There a special commission, consisting of Cardinals Mariano Rampolla, Andrea Steinhuber and J. C. Vives y Luto, with the Franciscan theologian David Fleming as secretary, was set up to look into the writings of Loisy and Tyrrell and appraise the whole modernist movement. On Dec. 16, 1903, Loisy's works were condemned at Rome and proscribed for all Catholics.

In 1904 Tyrrell published anonymously his *Letter to a Professor of Anthropology*, which, along with his earlier writings, was translated into Italian by P. Giacosa and Romolo Murri. The translation won enthusiastic reviews in the *Revista storico-critica delle scienze teologiche*, whose editor, Ernesto Buonaiuti, was an active modernist. He was also a warm supporter of D. Battaini, who was campaigning strongly against the church's regulations on clerical celibacy. Murri, Buonaiuti and Battaini popularized Loisy's ideas throughout Italy. On April 16, 1905, Edouard Le Roy published in *La Quinzaine* a closely reasoned article supporting Loisy's and Tyrrell's ideas on the nature of religious dogma, and this too was publicized in Italy by Buonaiuti. At Christmas 1905 the bishops of north Italy issued a joint pastoral letter condemning modernism and denouncing the work of Buonaiuti, Murri and Battaini. In the weeks that followed, Tyrrell was proved to be the author of the *Letter to a Professor of Anthropology*, and he was dismissed from the Jesuit order on Feb. 1, 1906.

Once Pope Pius X, successor of Leo XIII, had received the report of the commission set up to study modernism, he issued to the Italian bishops, on July 28, 1906, the encyclical *Pieni l'animo*, supporting the action of Cardinal Richard against Loisy and the stand of the north Italian bishops against modernism. He then appointed a new commission of scholars—Louis Billot, Umberto Benigni and Pie de Langogne—to draft a major encyclical on the subject of modernism. On April 17, 1907, in an address before the cardinals, he stigmatized modernism as "not a heresy, but the summation and essence of every heresy." On July 3, 1907, the Holy Office issued the decree *Lamentabili* condemning 65 propositions, on the subjects of the church, revelation, Christ and the sacraments, advanced by the modernists. And finally, on Sept. 8, 1907, was promulgated the encyclical *Pascendi*, which summarizes and rejects modernist teaching, traces the causes of the movement and suggests remedies that the church should use in extirpating it. *Pascendi* declares modernism to be an agnosticism which makes religious truth dependent on emotion and castigates it as a species of intellectual despair brought about by an ignorance of philosophy.

The means taken to enforce the condemnation of modernism included tightening of censorship of articles in theological journals and books dealing with Catholic dogma; scholastic philosophy and theology were to be taught in the seminaries by professors chosen with care and specially trained; furthermore, a special commission, composed of Cardinals Rampolla, Désiré Mercier and Pietro Maffi, was to be established to enforce these prescriptions (this, however, was never done).

On Nov. 18, 1907, Pius X confirmed the decree *Lamentabili* and the encyclical *Pascendi* and urged immediate compliance with his strict censorship regulations. These regulations, however, were based on the traditional canon law, which was as yet uncodified and consequently ambiguous and unclear. To ensure enforcement, Benigni organized, through his personal contacts with theologians, a non-official group of censors who would report to him in Rome those thought to be teaching condemned doctrine. This group, known as Integralists (or *Sodalitium Pianum*), though their zeal was commendable, often used methods similar to those employed by Fontaine in the Batiffol affair of 1901 and hindered rather than helped the combating of modernism. On June 29, 1908, Pius X publicly admitted that modernism was a dead issue, but at the urging of Benigni he issued on Sept. 1, 1910, *Sacrorum antistitum*, a *motu proprio* which prescribed that all teachers in seminaries and clerics before their ordination take an oath denouncing modernism and supporting *Lamentabili* and *Pascendi*.

For modernism as opposed to traditionalism in the Anglican Church, *see* ENGLAND, CHURCH OF: *Liberalism or Modernism*; for modernism in the Protestant use of the term, *see* LIBERALISM, THEOLOGICAL. *See also* references under "Modernism, Roman Catholic" in the Index.

BIBLIOGRAPHY.—The most complete treatment of modernism is Jean Rivière, *Modernisme dans l'Église* (1929), which the author summarizes in his article "Modernisme" in *Dictionnaire de théologie catholique*, vol. x, col. 2009–47. All the official church documents dealing with modernism are to be found in A. Vermeersch, *De Modernismo* (1913). Vermeersch also wrote the article "Modernism" for *The Catholic Encyclopedia*, vol. x, pp. 415–421. Correspondence and controversy among the modernists themselves have been edited by René Marlé, *Au cœur de la crise moderniste* (1960). For an accurate appraisal of the issues involved in the modernist controversy, Julius Bessmer, *Philosophie und Theologie des Modernismus* (1912), is still helpful, but should be corrected on the point of historical criticism by Lucio da Veiga Coutinho, *Tradition et histoire dans la controverse moderniste* (1954). P. Ferneuse, *Pie X: étude historique*, 2 vol. (1953), puts modernism in its historical perspective, as does E. E. Y. Hales, *The Catholic Church in the Modern World* (1958). Emile Poulat, *Alfred Loisy, sa vie, son œuvre* (1960), contains a bio-bibliographic index that is invaluable in identifying all the theologians involved in the modernist crisis. Helpful for its human account of the people involved in the controversy is M. Ward, *Insurrection vs. Resurrection* (1937).

**MODERN SCHOOL (GREAT BRITAIN)**, a secondary school providing a combination of general and practical education, which may include a foreign language, for boys and girls above the age of 11 not selected for grammar (academic) or technical schools. Some modern schools offer an extended, or fifth-year, course. *See* EDUCATION, HISTORY OF: SECONDARY EDUCATION.

**MODERSOHN-BECKER** (or BECKER-MODERSOHN), **PAULA** (1876–1907), German artist and a leader in the modern movement, was born on Feb. 8, 1876, in Dresden. As a pupil of Fritz Mackensen she became a member of the circle formed by the Worpsweder school, an artists' colony near Bremen. Between 1900 and 1906 she spent four periods of study in Paris, finding artistic inspiration in the Gauguin circle and the "Nabis" group. She soon transmuted this influence into a form of her own, however. She increasingly freed herself from the lyrically tinged naturalism of her early Worpsweder years and became, after Cézanne, Van Gogh, Gauguin and E. Munch, one of the founders of 20th-century painting. In her posed and figure compositions, her still lifes, portraits and self-portraits, she helped to a great extent to develop the expressive form language of modern painting several years before the Fauve and Brücke groups. In spite of her early death on Nov. 20, 1907, she left an extensive volume of work of about 400 paintings and more than 1,000 drawings.

(Ge. B.)

**MODES, MUSICAL.** The word mode (from Latin *modus*, "manner," "measure," "mood") has two meanings in music: (1) the ways of ordering the notes of a scale according to the intervals they form with the tonic note, thus providing a theoretical framework for melodic music. In this sense, the term is generally used in reference to the modes defined by the Roman Catholic Church for the classification of plainsong (q.v.), or plain chant, but it also includes the modern major and minor scales, as well as modes found in ancient and oriental music and in folk music the world over. (2) A way of ordering long and short notes so as to form metrical (rhythmical) patterns used chiefly in the 13th century. This article discusses the first meaning.

*The "Church" Modes*

| Name | Greek name wrongly applied | Authentic | Plagal | Notes | Finalis | Tenor |
|---|---|---|---|---|---|---|
| Protus authenticus | Dorian | I | | D E F G A B C D | D | A |
| Protus plagalis | Hypodorian | | II | A B C D E F G A | D | F |
| Deuterus authenticus | Phrygian | III | | E F G A B C D E | E | C |
| Deuterus plagalis | Hypophrygian | | IV | B C D E F G A B | E | A |
| Tritus authenticus | Lydian | V | | F G A B C D E F | F | C |

| | Hypoionian | | XII | G A B C D E F G | C | E |

**The Medieval Modes.**—The modes in Europe owe something of their structure and terminology to the octave species (*harmoniai*) of ancient Greece, which early influenced the Christian church. But because of medieval Europe's own musical instincts and certain differences among her musicians in the interpretation of Greek music theory, European modal theory went its own way (*see* GREEK MUSIC [ANCIENT]).

St. Ambrose, bishop of Milan (*c.* 340–397), was the first to organize the melodies of the church in four modes (*protus*, *deuterus*, *tritus*, *tetrardus*, corrupt forms of the Greek words for first, second, third and fourth; that is I, III, V and VII of the table). Each of these consists of: (i) an octave scale comprised of tones and semitones in different orders; (ii) a keynote, to which all the intervals of this scale are referable, called *finalis* since a melody written in such a mode ends on this note; (iii) a *tenor*, so-called as it was the holding note on or around which most of the recitation occurred. The tenor is normally, though not always, an interval of a fifth above the *finalis*, a feature that divides the mode into two conjunct segments: (1) a lower pentachord (series of five notes forming the interval of a fifth), and (2) an upper tetrachord (series of four notes forming the interval of a fourth). These four modes came to be called authentic (original). The Greek names applied to them, as to all other medieval modes (*see* table) are, through a medieval error, quite different from those referring to Greek modes of comparable structure.

Subsequently, Pope Gregory (*c.* 540–604) provided more variety by introducing four new modes, or rather a new form of each of the four original modes of Ambrose. These new forms (II, IV, VI and VIII in the table) each kept the same *finalis* as their parent modes but occupied a lower range of the voice. Thus the original lower segment (pentachord) was retained, the original upper segment (tetrachord) being transposed an octave lower, *i.e.*, it was placed below the pentachord instead of, as formerly, above it. The *finalis* now occupied the middle of the scale, and the scale ran from the authentic tenor to its octave. But in order to avoid the reciting note being at the extreme ends of the scale the tenors were given new places as shown. These new modes were called plagal (from Greek *plagios*, "oblique") and their adopted Greek names were given the prefix *hypo-* ("below"), in reference to their compass being lower than that of the authentic modes. A mode of more extended compass, *i.e.*, including both authentic and plagal notes, is called a mixed mode.

By the end of the 8th century, a considerable time after Pope Gregory's redaction of the original corpus of melodies, this system of eight modes, known as the *oktoechos*, became the basis for classifying the melodies of plainchant. Many of the chants are indeed thus adequately classified, though others do not conform to the modes under whose appellation they appear, while others again have been deliberately modified to conform more closely. The system has, however, always remained the official basis of church music, and its modes are usually called "church modes" or "ecclesiastical modes," though they were also the principal basis for the works of composers generally until about 1500 and are found in folk music.

The next enrichment of modal theory was due to the Swiss monk Glareanus (Henry of Glarus, 1488–1563). Recognizing that each of the seven notes of the scale could form the *finalis* of a mode, Glareanus described, in his *Dodecachordon* (1547), three further pairs of modes, on the notes A, B and C. The authentic mode on B (Locrian) and its plagal derivative (Hypolocrian) he rejected since they had no true pentachord or tetrachord but possessed only the imperfect fourth F–B, called *diabolus in musica*. But the mode on *finalis* A (Aeolian, with its plagal derivative Hypoaeolian) and the mode on *finalis* C (Ionian, with its derivative Hypoionian) he admitted (IX, X, XI and XII in the table), thereby completing the set of twelve modes underlying melodic music.

The Aeolian and Ionian modes, virtually the modern minor and major scales (the *finalis* now being called tonic, and the tenor becoming dominant), had been rejected by the medieval church, the Ionian being called *modus lascivus* because of its popularity in secular music, in which it is found from the 11th century at latest. But of all the modes, it lent itself most to the harmonic feeling which was awakening in Europe, though it was not officially recognized by the church until the 16th century. Meanwhile, the efforts of musicians to avoid the tritone interval explains not only why the tenors of modes III and VIII settled on C rather than (by analogy with other modes) on B but also why altered notes gradually crept in, first B♭, later F♯, then E♭, C♯ and G♯, to create a system called *musica ficta*, in which these accidentals, although often not written, were executed by the performers according to certain rules. This practice, used especially at cadences, also modified the modes in the direction of the modern major and minor scales.

**The Modes Since 1600.**—From 1600 to 1900, the major and minor "scales," *i.e.*, virtually the Ionian and the Aeolian modes in their authentic forms, came to be used exclusively. For the major and minor scales are no less modes than the medieval structures. They are to be distinguished from keys, which are a device for transposing a given mode. A given mode can indeed be taken in any key. All major keys are modally identical (*i.e.*, their notes always have the same relation to the tonic), the difference between one major key and another being in the pitch of the tonic. Similarly, all the different modes can be transposed so as to start from the same key note; thus following the notes of the piano from C to C, the Lydian has F♯, the Ionian is all on the white keys, the Mixolydian has B♭, the Dorian B♭ and E♭, the Aeolian B♭, E♭ and A♭ and the Phrygian B♭, E♭, A♭ and D♭.

In modern times, the minor mode has three forms (*see* also

SCALE: *Diatonic Scale*). Two of these are for melodic purposes: descending (cf. mode IX, Aeolian); and ascending, where the upper tetrachord is major, viz., A B C D E F♯ G♯ A. In the third form, the harmonic minor, the upper tetrachord is, in the Greek sense, a chromatic genus, viz., A B C D E F G♯ A; that is, its tetrachord has two intervals of a semitone and one interval of a minor third, as opposed to the diatonic genus which, in its patterns of tones and semitones, characterizes all the other western modes.

During the period of the greatest popularity of the major and minor modes, *i.e.*, that of "classical music," the church modes, still kept for plainchant, tended to disappear in other music. Though the traditional material used by J. S. Bach is sometimes modal, his treatment of it is rarely so. After his time, modal thinking is exceptional, though rare instances occur in Beethoven's A minor Quartet, in which the slow movement has a Lydian theme, and in Bruckner's Symphony No. 6, in which the finale has a Phrygian theme. But a freer use of the modes was again found around the beginning of the 20th century as a result of the awakening interest in folk music and in plainchant, and of the tendency to use archaisms. The interest in folk music also reintroduced the modes of the anhemitonic (*i.e.*, without semitones) pentatonic scale.

**Ancient and Oriental Modal Systems.**—Toward the middle of the 20th century the western world became aware of living modal systems in the music of the Orient and of some of the systems used in antiquity. These systems are different from those of the west in many ways. The differences concern the range of notes (octave in Byzantine and Roman chant and in Indian classical music; tetrachord in Persia, as in ancient Greece); the direction of the modal scale (descending in ancient Greece, ascending in the west; both directions in India); the size of the intervals (diatonic only in Europe; often finer shades of interval in the east); and the number of focal notes which may be added to the dominant. Yet despite these differences, all these systems are related through their fundamental principle, namely, the relationship of each note to a permanent and immovable tonic and hence to each other. This tonic may be sounded only occasionally, and only in the melody, as the western *finalis* or tonic; or it may be permanently (or intermittently) sounded as a reference note throughout a performance, like the Indian *chhandozati sruti*, Byzantine *ison* and the bagpipe drone. Even European sacred music made considerable use of drones until at least the 12th century. The constantly sounding tonic lends the melody notes a far more certain expression than they have when left without a continuous point of reference.

The modal systems of music (ancient Egyptian and Mesopotamian, Greek, Jewish, Indian, Persian and Arab; Byzantine and Roman Christian; European till *c.* 1600) are different in principle from systems employing transposition (with a measure of modulation). The latter systems, based not on the division of a string (and its octave unit) but on the cycle of fifths (as in the music of Pythagorean Greece, China, and Europe since *c.* 1600), favour the development of harmony, though this is, strictly speaking, incompatible with a full modal system. The two systems, the divisive (modal) and the cyclic (transposing), were first confused by the later Greeks; the confusion continued in Europe, though European harmony first developed within the western modal system.

**Modal Ethos.**—The essence of mode lies in its mood. Indeed, the eight medieval western modes have been described as being respectively: I, grave; II, sad; III, mystical; IV, harmonious; V, joyful; VI, devout; VII, angelic; VIII, perfect. Here is an echo of the Greek concept of *ethos* or moral effect of modes. Some ancient peoples still traditionally regard music as, in its own language, reflecting the pattern of the universe or of divine nature. They regard *phenomena* (things apparent to the senses) as ideally reflecting *noumena* (principles lying behind all appearances)—Plato's *mimesis*—and in this view a mode of music, properly so-called, is part of a larger mode running through all existence. *Modus* also means measure, that is, the precise measure of a modal note in relation to its tonic, which indeed goes hand-in-hand with mode's particular expression (mood) and manner. This measure can be expressed as a ratio of string lengths or (in modern times) of vibration frequencies. Hence the number correspondence and number symbolism inevitably connected with *ethos*. Tribute is paid to the ancient beliefs about modal *ethos* in the myths which have come down—myths telling of marvelous music which can create and destroy, kill and cure, music which can influence and indeed control man's every mood. *See also* MUSIC IS ANCIENT CIVILIZATIONS.

**MODICA,** a town of Ragusa province in Sicily, Italy, is situated at the confluence of two mountain torrents, the site of the Siculi town of Motyca, 72 km. (45 mi.) S.W. of Syracuse by road. Pop. (1961) 44,030 (commune). That Modica was once a wealthy city is shown by the church of Sta. Maria di Gesù with its adjacent cloister, the portal and rose window of the church of the Carmine; the De Leva portal and Arab-Norman chapel of the church of Sta. Maria di Bethlemme; and the massive baroque church of S. Giorgio in the upper town. About 9 km. (5½ mi.) from Modica is the famous Cava d'Ispica, enriched with thousands of natural grottoes, which were used for habitation and as tombs from before the 14th century B.C. The town is on the railway from Syracuse to Ragusa and Agrigento. Agriculture is important and there is also light industry and traditional local crafts. One of the oldest cities of Sicily, Modica was an impregnable Bronze Age (and perhaps Stone Age) fortress. The capital of a fief from the 12th to the 17th centuries, its counts rivaled in power and wealth the viceroys of Sicily. It was almost entirely destroyed by the earthquake of Jan. 11, 1693 and devastated by flood in 1902. (G. M.-Sc.)

**MODIGLIANI, AMEDEO** (1884–1920), Italian painter and sculptor and a leading figure among the Parisian artists of his day, was born of a Jewish family at Leghorn on July 12, 1884. Modigliani studied at the academies of Venice and Florence, his early admiration for Italian Renaissance painting—especially Sienese—was to last him all his life. In 1900 he left Italy and settled in Paris, first in Montmartre and subsequently in Montparnasse, where he remained until his premature death on Jan. 24, 1920. After 1915 his health had slowly deteriorated, in spite of the devoted care of his wife Jeanne Hebuterne and his friend and dealer Leopold Zborowski. Addiction to drugs and alcohol certainly hastened his end. His wife leaped from a window a few days after his death, killing herself and an unborn child.

The first paintings done by Modigliani in Paris (*e.g.*, "L'Amazone" of 1908) show the influence of Henri de Toulouse-Lautrec and of Picasso's early work. Very soon, however, he turned to Cézanne, as can be clearly seen from "Le Violoncelliste" and "Le Mendiant de Livourne" (both 1909). Between 1910 and 1914 Modigliani seems almost to have abandoned painting for sculpture. His drawings had attracted the attention of Constantin Brancusi, who encouraged him to carve heads and figures in stone. Several heads were shown at the Salon d'Automne in 1912; their elongations and simplifications reflect the influence of African art.

Late in 1914 financial difficulties forced Modigliani to begin painting again. The impact of Cubism may be seen in portraits such as that of Beatrice Hastings (Barnes foundation, Merion, Pa.), the English poetess with whom he lived from 1914 to 1916. However it was not Cubism but the characteristics of Modigliani's sculptured heads—long necks and noses, simplified features and long oval faces—that soon pervaded his painting. These mannerisms are first noticeable in the oil portraits that he made between 1915 and 1917 of many leading figures of Montparnasse artistic life. During the last three years of his life Modigliani painted mainly nudes and portraits of women.

Modigliani was a superb natural draftsman, as his many drawings bear witness. As a painter his style was a tight, linear one;

unlike his Cubist and Fauvist contemporaries in Paris, he was little concerned with analysis of form or with the expressive qualities of colour. He might indeed have remained a sculptor had not his development been interrupted in 1914. Like most sculptors he was almost exclusively interested in the human figure; he painted no still life and only three landscapes. Modigliani's men and women and children are presented very directly, usually seen half-length or head alone against a simple background. Their most remarkable aspect is the entirely personal atmosphere with which they are invested: a kind of mute sympathy between artist and sitter that implicates the spectator and helps to account for Modigliani's enormous popularity.

**MODJESKA, HELENA** (HELENA MODRZEJEWSKA, née OPID) (1840–1909), Polish-U.S. actress, whose repertory included several Shakespearean roles and a variety of emotional parts in modern drama. The daughter of a musician, Michael Opido, she was born at Cracow, Pol., on Oct. 12, 1840. After her marriage, to a Pole, Gustav Modrzejewski, she joined a company of strolling players. In 1868 she married Count Bozenta Chlapowski, a Polish politician and critic, and began to act at Warsaw, where she remained for a number of years. Her chief tragic roles were Ophelia, Juliet, Desdemona, Queen Anne in *Richard III*, Louisa Miller, Maria Stuart, Schiller's Princess Eboli, Marion Delorme, Victor Hugo's Tisbé and Juljusz Slowacki's Mazeppa. In comedy her favourite roles were Beatrice in *Much Ado About Nothing*, and Donna Diana in the Polish translation of an old Spanish play of that name. Mme Modjeska also played in modern pieces by Gabriel Legouvé, Dumas (father and son), Guillaume Augier, Alfred de Musset, Octave Feuillet and Victorien Sardou. In 1876 she went with her husband to California, where they settled on a ranch. This enterprise was a failure, and Mme Modjeska returned to the stage. She appeared in San Francisco in 1877, in an English version of *Adrienne Lecouvreur*. She continued to act principally in the United States, but was also seen from time to time in London and elsewhere in the United Kingdom. Mme Modjeska died on April 9, 1909, near Los Angeles, Calif.

**MODJESKI, RALPH** (1861–1940), U.S. engineer, gained recognition for his distinguished work as a designer and builder of bridges. He was born at Cracow, Poland, Jan. 27, 1861, the son of the actress Helena Modjeska. He graduated from the École des Ponts et Chaussées, Paris, with high honours, and then settled in the United States. From 1892, he practised as consulting bridge engineer at Chicago, Ill. Among his best-known bridges are the government bridge over the Mississippi at Rock Island; the McKinley bridge at St. Louis; bridges over the Mississippi at Thebes (Ill.) and at Memphis (Tenn.); the Northern Pacific bridge over the Missouri at Bismarck (N.D.); and bridges over the Columbia and Willamette rivers in Oregon. Modjeski was a member of the Quebec Bridge commission, and consulting engineer for the Ohio river bridge at Metropolis (Ill.) for the Chicago, Burlington and Quincy railroad, and the Thames river bridge at New Haven (Conn.) for the New York, New Haven and Hartford railroad. He was chosen chief engineer and chairman of the board of engineers of the Philadelphia-Camden bridge over the Delaware river, which, on its completion in 1926, was the longest suspension bridge in the world.

Modjeski was appointed chief engineer of the Huey P. Long bridge over the Mississippi at New Orleans, and served as chairman of the board of consulting engineers for the Trans-Bay bridge at San Francisco, completed in 1936. He died in Los Angeles on June 26, 1940.

**MODOC,** a North American Indian tribe that formerly ranged between Klamath lake, Oregon, and Clear lake, California. In speech and custom there was little distinction between them and the Lutuamian-speaking Klamath, their near neighbours to the north. In 1864 the two tribes agreed to relinquish most of their territory and take up residence on a reservation around Upper Klamath lake. However, an insurgent band of Modocs under the leadership of Kintpuash, a subchief known to the whites as Captain Jack, bolted the reservation in 1870, and efforts to induce their return precipitated the Modoc war of 1872–73. About 80 warriors and their families retreated to the bad lands in the vicinity of the Lava Beds National monument, where they were able to resist dislodgment. Following the treacherous murder of Gen. E. R. S. Canby, who headed a peace commission in April 1873, the war was prosecuted more vigorously. Captain Jack surrendered and was hanged in October of the same year. His followers were removed to Oklahoma. In the 1960s less than 30 Modoc were reported from Oklahoma; others were sharing lands with the Klamath and Snake in Oregon with a combined population of less than 1,200.

**MODULATION,** a musical term signifying the transition in diatonic harmony from one key to another achieved by the use of chords common to both keys. In the harmonic technique of the 18th-century sonata form, modulation determines the breadth and range of expression of a movement, allowing developments of themes on different tonal planes. At the end of the 19th century it became identified with chromaticism. There are three main methods of modulation in classical harmony: diatonic, in which a pivot chord is common to two tonalities; chromatic, in which a note or notes in the pivot chord require alteration by a semitone; and enharmonic, in which the notes of the pivot chord assume different names (*e.g.*, the chord C♯ E♯ G♯ changed enharmonically to D♭ F A♭). Modulation may be transitory, as a means of giving depth to thematic development, or it may be structural. The latter type is a principal consideration in the design of a musical form. *See* also HARMONY: *Tonality, Time Scale, Movement and Modulation;* CHROMATICISM; ENHARMONIC.

**MODULATION (ELECTRONIC),** the process by which some characteristic or characteristics of one wave (the carrier) are caused to vary in accordance with the instantaneous amplitude or frequency of another wave (the signal).

Speech provides a familiar example in which the mouth varies or modulates a sound stream to produce recognizable words. The mere production of a steady tone conveys no intelligence unless the tone is interrupted, such as by turning it off and on in accordance with some prearranged code. This type of modulation is synonymous with that used in the familiar dot-dash telegraphic code.

In radio or the audio portion of television, the transmission of a steady signal by the transmitter tells nothing except that the station is or is not operating. Speech, music and other wave forms can be transmitted by a refinement of the modulation scheme described for telegraphic code, such as causing the amplitude or frequency of the transmitted wave to vary in direct proportion to the frequency of a sound or picture signal. If the amplitude is varied, the process is called amplitude modulation (AM); if the frequency is varied, frequency modulation (FM).

Because of unsatisfactory antenna radiation at low frequencies and the desirability of operating on many frequency levels to allow simultaneous transmission of many programs without interference, as well as the presence of filtering problems, it is necessary to use a high-frequency carrier and to modulate it with a low-frequency signal. The high frequency carrying the modulation is commonly termed the R.F. (radio frequency) carrier.

In addition to the AM and FM schemes already mentioned, phase modulation and pulse modulation are also used, the latter finding application in radar and other tracking devices. *See* also RADIO; RADIO RECEIVER. (A. L. Sv.)

**MODULE,** in architecture, is an arbitrary unit adopted to regulate the dimensions, proportions or construction of the parts of a building. A number of modules, based on the diameter of a column, were used in determining the proportions of the order (*q.v.*) in classical architecture. In Japanese architecture, room sizes were determined by combinations of 3-ft. by 6-ft. rice mats called *tatami*.

In modern architecture, design modules may be used to spread the proportioning and dimensioning of plans. The metre has proved useful for this purpose; Frank Lloyd Wright used a 4-ft. rectilinear or diagonal grid; and Le Corbusier developed and widely published an additive proportioning system named by him the *Modulor*. Other modules reflect repetitive building elements such as the standard office size or the hospital bed unit.

In addition to these applications in space planning, modules may also serve as the basis for co-ordinating the dimensions of the various materials and pieces of equipment to be assembled in the course of constructing a building. The purpose is to assure that all of the elements will go together without wasteful cutting and fitting at the building site, and to lower costs by permitting the quantity production and distribution of modular products with the assurance that they may be incorporated into any building plan.

An increasing amount of attention has been devoted to this subject since the development in the 1930s of the Bemis 4-in. cubical module (10 cm. in Europe), and progress has been made in stimulating the manufacture of modular building products. In the 1950s an effort was made to combine into a single "number pattern" several of these modular systems to offer the designer a larger range of approved dimensions in the critically important first few feet and to reduce the cost to the manufacturer of converting to modular products. Most architects and producers of building materials continued, however, to use modules based on their own special needs and interests, without co-ordination.

**MOE, JØRGEN ENGRETSEN:** *see* ASBJØRNSEN, PETER CHRISTEN.

**MOERAN, ERNEST JOHN** (1894–1950), English composer born at Heston and Isleworth, Middlesex, on Dec. 31, 1894, whose "pastoral" idiom resembles that of Frederick Delius and John Ireland, though it displays less harmonic sophistication. He was much influenced by folk song and made arrangements of tunes that he collected, chiefly in Norfolk and Suffolk. His individuality is best seen in his many solo and choral songs, which include settings of Shakespeare, Robert Herrick, A. E. Housman, James Joyce and Seumas O'Sullivan. He was also successful in the larger forms. Among his more ambitiously designed works are the Symphony (1937), concertos for violin and cello, and several chamber works. Although limited in emotional range and variety of thematic invention, his larger works are accomplished in form and well sustained. He died near Kenmare, County Kerry, Republic of Ireland, on Dec. 1, 1950.

**MOERIS, LAKE OF,** an ancient lake which once occupied a large area of the Fayyum depression in the Fayyum province of Egypt; it is now represented by the much shrunken Birkat Qarun. The researches of archaeologists and geologists on the desert margin of the depression have done much to elucidate the history of the lake and the problem of its extent and level in ancient times. It would appear that in early Paleolithic times water stood about 120 ft. above sea level and probably filled the depression. In the Mousterian period, the level stood rather lower, at 105 ft.; during the Late Paleolithic it fell slowly and then, c. 10,000 B.C., more rapidly to about 15 ft. below sea level, perhaps because free connection with the Nile was temporarily cut off. Early in the Neolithic period the lake rose once more, and then gradually subsided, remaining at times long enough at one level to allow the formation of beaches which can still be seen. On the slowly shrinking shores, Neolithic fisher folk made their homes. They were succeeded by villagers of the early dynastic age. It was not until the Middle Kingdom, c. 1950 B.C., that action was taken by the Pharaohs to stop the gradual silting of the channel that connects the lake with the Nile through the Hawara gap. It may have been Amenemhet I who widened and deepened the channel, setting the lake once more in hydraulic equilibrium with the river; the lake, then 55 ft. above sea level, served both as a flood escape and as a reservoir to increase the supply of water for cultivation after the flood had subsided. About 450 B.C. Herodotus visited the lake. He described it as being 3,600 furlongs in circumference and 50 fathoms deep; he assumed that it was artificial and was told that it had been dug by King Moeris at least 900 years before. He described two colossal statues, the bases of which, bearing an inscription of Amenemhet III, were found by Flinders Petrie at Biahmu.

Large land reclamation schemes were carried out by the Ptolemies in the Fayyum. Lake Moeris was partially drained by Ptolemy II Philadelphus by means of a barrage to restrict the entry of Nile water, and the rich soil (approximately 450 sq.mi. [1,200 sq.km.]) thus laid bare was irrigated by canals and subjected to intensive cultivation. The population grew rapidly and towns sprang up, among them Soknopaiou Nesos, Karanis, Bacchias, Dionysias, Euhemeria, Philoteris and Theadelphia. The ancient Crocodilopolis, or Shedet, seat of the worship of Sobek the crocodile god, became Arsinoe, the capital of the Arsinoite nome. The excavation of sites around the lake has yielded a rich harvest of papyri of Hellenistic and Roman date.

The province continued to flourish during the first two centuries of Roman rule, but thereafter declined. The *Kitab Ta'rikh al-Fayum* of Abu Osman al-Nabulsi, written in A.D. 1245 when he was governor of the Fayyum, deplores the decrease of its waters. The Birkat Qarun today is very shallow and covers only 50 sq.mi.

**MOERS** (MÖRS), a town of Germany in the *Land* (state) of North Rhine-Westphalia, which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 46,650. It lies 7 km. (4½ mi.) W. of Duisburg near the Rhine and is served by the Duisburg-Cleves and Oberhausen-Krefeld railways. The site of the Roman Asciburgium (located in the Asberg quarter), Moers was first mentioned in the 12th century and developed as a medieval flax market around the castle of the counts of Moers (now a museum). A charter was granted by King Albert about 1300. In 1600 the town became the property of Maurice of Nassau, prince of Orange, who fortified it. The county passed to Prussia in 1702 and the fortifications were razed by Frederick the Great in 1763. The old part of the town is surrounded in part by a 3-km.-long outer fortification wall with a moat and star-shaped dam and has some narrow crooked streets and half-timbered houses. Moers became important industrially after 1900 when it grew as the centre of the Lower Rhenish mining industry. Marketing activities focus on the town centre. On the outskirts many industrial concerns have been set up. Manufactures include machinery, heating equipment, cement, blankets and tents. There are colleges of mining technology and agriculture, and the Gymnasium Adolfinum continues the tradition of the Protestant college founded in 1582.

**MOESIA,** the Roman province (later two provinces) immediately south of the lower Danube, bounded to the west by the Drinus (Drina) river and to the south by the Haemus (Balkan) range. The many tribes of this region (the Moesi proper were Thracians inhabiting present-day Serbia) had frequent encounters with the Romans before they were subdued by M. Crassus (grandson of the triumvir) in 30–28 B.C., bringing the frontier of the empire to the Danube. The newly conquered region was at first part of the province of Macedonia, then (perhaps about A.D. 4) it was detached as a military district under a consular commander; only in A.D. 15 was it made a regular stipendiary province. In the latter year, though still retaining its identity, it was grouped again with

Macedonia and Achaea, an arrangement that lasted till 44. During his Dacian wars (*c.* 86) Domitian divided the province into Moesia Superior west of the Ciabrus (Tsibritsa) river and Moesia Inferior from there to the Black sea. After Trajan's annexation of Dacia (106), Upper Moesia was extended north of the Danube to include most of the Banat, and Lower Moesia acquired large tracts of Moldavia and Walachia. When Dacia was abandoned *c.* 270 its inhabitants were largely transferred to Moesia, and the provinces were called Dacia Mediterranea and Dacia Ripensis. The garrison was gradually increased. Under Tiberius there were only two legions; one more was added after the annexation of Thrace (*q.v.*); Vespasian probably added a fourth; and after the division the two provinces together were garrisoned by five.

Moesia included the Greek cities near the Danube mouths, such as Istrus, Tomi (Constanţa) and Mesembria (Nesebur). In the 1st century it was not always easy for the Romans to defend them, especially under Domitian, when a wall to the south of them was built from Rasova on the Danube to Constanta; but at most periods they continued to be exceedingly prosperous, not least because surplus corn from the Black sea area could always find a market in the Roman empire. The other principal cities of Moesia grew out of the legionary camps along the Danube, from Singidunum (Belgrade) to Troesmis in the Dobruja. There too there was a strong Greek element, since the Moesian legions in the 1st century drew many recruits from the Greek-speaking provinces. In the interior agriculture and fruit-growing flourished, and there was mineral wealth in the Balkan range. The country suffered heavily from barbarian invasions from the mid-3rd century onward, but it was held for the Eastern Roman empire until the 7th century.

**MOFFAT, ROBERT** (1795–1883), pioneer missionary and father-in-law of David Livingstone, was born at Ormiston, East Lothian, on Dec. 21, 1795, and sent to South Africa by the London Missionary society in 1816, with little formal training for the work of a missionary. The first seven years of his work were much distracted by the unsettled state of the country; but in 1824 he was settled at Kuruman, southeast of the Kalahari desert, which was to be his home for 49 years. Moffat traveled widely, and made the acquaintance of many tribes. He acquired a profound knowledge of the Tswana language, into which he translated the Gospel of St. Luke (1830). Up till that time the mission had made little progress, but thenceforward the number of converts increased steadily. By 1857 Moffat had translated the whole Bible. He also introduced the Africans to better methods of agriculture and irrigation and in every way raised their standards of living and conduct, though his methods were perhaps unduly patriarchal. On his first meeting with Livingstone in 1840 Moffat detected his fine qualities and encouraged him to come to Africa, but wisely directed his attention northward "where no missionary had ever been." After the death of his wife Mary, who had shared 50 years of his missionary work, Moffat lived in retirement in England for the last 13 years of his life, and died at Leigh, Kent, on Aug. 9, 1883.

(S. C. N.)

**MOFFAT,** a small burgh in Upper Annandale, Dumfries, Scot., situated on the Annan river, 21 mi. N.N.E. of Dumfries by road. Pop. (1961) 1,917. Moffat was famous for its sulfur and saline waters in the middle of the 18th century, and is now a vacation and angling resort. The spa lies 1½ mi. N.E. of the town, and there are also springs at Hartfell (3½ mi. N.) and Garpol (2 mi. S.W.). At Moffat house, which is now a hotel, James Macpherson published "Ossianic Fragments."

Dumcrieff house, outside the town, a former seat of Lord Rollo, was the home of J. L. McAdam, the road builder.

**MOFFATT, JAMES** (1870–1944), eminent Scottish scholar and author of one of the best-known translations of the Bible in modern idiom, was born on July 4, 1870, at Glasgow, and educated there at the academy, the university and the Free Church college. He was ordained in 1896 and, after pastorates in the ministry of the United Free Church of Scotland, was Yates professor of Greek and New Testament exegesis at Mansfield college, Oxford (1911–15), professor of church history at the United Free Church college, Glasgow (1915–27), and then Washburn professor of church history at the Union Theological seminary, New York (1927–39), where he died on June 27, 1944.

Though most of Moffatt's teaching was done in the field of church history, to which he contributed a translation of A. von Harnack's *Expansion of Christianity* (1904–08) and his own *First Five Centuries of the Church* (1938), it was as a biblical scholar that he won his great reputation. Besides commentaries on Thessalonians, Hebrews and Revelation, he wrote *Introduction to the Literature of the New Testament* (1911), which after several revisions is still a standard work. Out of a total of about 40, the other most significant books are perhaps *The Theology of the Gospels* (1912), *The Approach to the New Testament* (1921), *Love in the New Testament* (1929) and *Grace in the New Testament* (1931).

But Moffatt will be remembered chiefly for his translation of the Bible. Though often criticized as unduly colloquial, it has for that very reason admirably captured the flavour of much of the New Testament (published 1913), while many parts of the Old Testament translation (published 1924), such as the Book of Job and the great prophetic passages, have high literary merit. Moffatt edited a popular series of New Testament commentaries based on his own translation, and was himself responsible for the volumes on I Corinthians (1938) and the Catholic Epistles (1928).

**MOFFAT TUNNEL,** begun in 1923 and completed in 1928, is 6.1 mi. long and pierces the continental divide 50 mi. W. of Denver, Colo., at an elevation of about 9,200 ft. above sea level. The 16 by 24 ft. tunnel, which provides for a single-track, standard-gauge railroad, was driven parallel with and 75 ft. to the north of an 8 by 8 ft. water tunnel with which it is connected at about 1,500-ft. intervals by crosscuts. *See* TUNNEL.

**MOGADISHU** (MAQDISHU; Italian MOGADISCIO), principal port and capital of the Somali Republic (*q.v.*), lies 2° N. of the equator on the Indian ocean coast of northeast Africa. Pop. (1961 est.) 99,762, mainly Somali, but including also immigrant Asians and Europeans. It was one of the earliest Arab settlements on the east African coast, its origins going back at least to the 10th century. Many old Muslim buildings and mosques have been preserved, which blend harmoniously with modern architecture. The Garesa palace, built by the sultan of Zanzibar in the 19th century, houses a museum and library. The republic's national assembly sits in an impressive centrally located building. There is a new university institute, and on the outskirts a large modern hospital. The airport is served by international services.

(I. M. L.)

**MOGADOR** (officially ESSAOUIRA), a seaport on the Atlantic coast of Morocco, chief town of a *cercle* (administrative subdivision) of the same name, in the province of Marrakech, about midway between Safi and Agadir. Pop. (1960), city, 26,392; *cercle*, 323,385. The town stands from 10 to 20 ft. above high water on a projecting ridge of calcareous sandstone. In certain states of wind and sea it is turned almost into an island, and a sea wall protects the road to Safi. On the land side stretch miles of sand dunes studded with broom, and beyond, the argan forests, distinctive of southern Morocco. Approached from this side the city bursts on the view like a mirage between sky and sea. The harbour is well sheltered from all winds except the southwest, but escape is difficult with the wind from that quarter, as the channel between the town and Mogador Island is narrow and hazardous. Mogador has a fish-processing industry, tanning and palm-fibre working.

The earlier hypothesis of a Phoenician settlement at Mogador has been confirmed by archaeological excavations which brought to light numerous Carthaginian traces. A place called Mogador,

a corruption of the Berber name Amogdul, is marked in the 1351 portolan chart in the Laurentian library at Florence, and the map in Jodocus Hondius' 17th-century *Atlas minor* shows the island of Mogador, *I Domegador* (the Portuguese had a fortress there from 1506 to 1510); but the origin of the present town is much more recent. Mogador was founded by Sultan Sidi Mohammed ben Abdallah in 1765, built to the plan of a French engineer and fortified in the style of Vauban. It was at first settled by an important Jewish colony, which for long had relations with England. In 1844 the citadel was bombarded by the French. Mogador was temporarily occupied by U.S. troops in Nov. 1942. After independence the official name of the town became Essaouira ("the little fortress"), a name it had previously held locally. (A. AM.)

**MOGILA, PETER** (1596–1646), Orthodox metropolitan of Kiev, author of the *Orthodox Confession of the Catholic and Apostolic Eastern Church*, belonged to a noble Moldavian family. He studied in Poland and possibly in the west, although no evidence exists for an alleged stay at the Sorbonne in Paris. In 1626 he took his monastic vows at the famous Kievan Pecherskaya Lavra and was appointed abbot in 1627. In 1633 he was elected metropolitan of Kiev. He made great efforts to improve the education of his clergy and laity at a time when both Roman Catholic and Protestant missionaries were very active among the Orthodox population of Poland and the Ukraine. In 1633 he transformed the theological college of the monastery into an academy which became the source of the theological revival in the whole Russian church; its influence was felt until the end of the 19th century. Theology in Kiev was taught according to the methods of western scholasticism and accepted many of the teachings of St. Thomas Aquinas. Mogila is known as the promoter of the *Orthodox Confession*, drawn up at the request of Abbot Kosslowski of Kiev, approved at a provincial synod in 1640 and accepted by the patriarchs of Constantinople, Jerusalem, Alexandria and Antioch in 1642–43 and by the Synod of Jerusalem (*q.v.*) in 1672. In spite of this recognition the *Orthodox Confession* has remained an object of controversy among Orthodox theologians, several of whom criticize it for its Latin spirit. Mogila died at Kiev on Dec. 22, 1646. *See* also CATECHISM: *Orthodox*.

**MOGILEV,** an *oblast* (established 1938) of the Belorussian Soviet Socialist Republic, U.S.S.R., lies in the middle Dnieper lowland, covering an area of 11,081 sq mi. Pop. (1959) 1,166,081. It forms a level plain, sloping gently southward from the loess-covered morainic hills of the Orsha and Smolensk-Moscow uplands in the north. Drainage is by the Dnieper, which bisects the *oblast* from north to south, and its tributaries. Soils are mostly podsolized clay loams, but sands are common. The natural vegetation is mixed forest of pine, spruce, oak and birch and more than one-quarter of the land is forested. Swamps cover nearly one-fifth of the area. Of the 1959 population 31% were urban, living in 13 towns and 10 urban districts. The largest are Mogilev (121,712), the administrative centre, Bobruisk (97,530), Krichev (19,028) and Osipovichi (15,777). Industry, chiefly engineering and timber processing, is largely concentrated in Mogilev and Bobruisk, but food processing, sawmilling and linen weaving are widespread. Flax growing and cattle rearing, especially dairying, are the main branches of agriculture. (R. A. F.)

**MOGILEV** (MOHILEV), town and *oblast* centre of the Belorussian Soviet Socialist Republic, U.S.S.R., stands on both banks of the Dnieper 110 mi. E. of Minsk. Pop. (1959) 121,712. It is an important industrial focus, producing metal pipes, building and lifting machinery, artificial fibres, leather goods, bricks, beer, wine and foodstuffs. Railways link the town to Minsk, Vitebsk, Bryansk and Gomel, and there are regular passenger and cargo services on the Dnieper. There is a reference to a fortress (1267) around which Mogilev probably developed. It is first mentioned as a town in 1526, when it belonged to Lithuania–Poland. Four churches of the 16th–17th centuries have survived. Russia acquired Mogilev in 1772 by the first partition of Poland but, although a seat of a *gubernuya* (as a province was called until the Revolution), it remained unimportant until the coming of the railway in 1904. Occupied by the Germans in World War II, the town was gravely damaged and its population fell from 113,000 to 10,000. (R. A. F.)

**MOGOK,** formerly a small district of Burma including the famous ruby-mining area. As the importance of the ruby mines waned the area was attached first to Katha district, and later to Shwebo. The washing of superficial gravels and sands for rubies, spinels and other precious stones was carried on from early times. By tradition women were free to do this work but not men. Large-scale working was long the monopoly of the Burma Ruby Mines Ltd., a British company, but synthetic rubies ruined the market for the real stones and after many vicissitudes the company ceased operations in 1927. The system adopted was to excavate large open pits from which the ruby-bearing earth was removed and washed by machinery. The rubies were traced to their bed rock site near the junction of gneissic and calcareous rocks and some attempt was made to work the parent rock but the stones proved inferior to those naturally weathered out. There is still panning of superficial deposits by local workers. Mogok is situated high on the Shan plateau and, reached by motor road from Thabeikkyin on the Irrawaddy, serves to some extent as a hill station.

(L. D. S.)

**MOGOLLON.** The Mogollon culture was one of three ancient major Indian cultures of the southwestern United States region and is significant because it reveals the little-known formative stages through which all civilizations pass. The area once occupied by the Mogollon Indians lies in east central and southeastern Arizona and west central and southwestern New Mexico. Much of this country is mountainous, in contrast with the high plateau country occupied by the Anasazi Indians and the low desert area occupied by the ancient Hohokam Indians.

The Mogollon culture developed from a relatively simple one, the Cochise, a culture which is characterized as a food-gathering rather than a hunting complex, for nuts, roots and edible plants were collected and formed the principal part of the Cochise food pattern, although a few animals were hunted for food. Primitive stone tools such as milling stones, mortars, pestles, choppers and scrapers were made and used. The Cochise did not develop pottery, houses or agriculture.

At some time between 4000 and 2000 B.C. corn or maize was introduced into the southwest, probably from Mexico. Soon after this, beans and squash made their appearance. After the introduction of these plants, more food was available, permitting a larger population and more leisure. Men had time to develop new arts, skills and inventions. For example, in the course of a few centuries, pottery and houses appeared. The houses were built below ground level and are called pit houses. Thus to the basic Cochise culture traits such as easily recognizable types of stone tools were added brown or red pottery, pit houses, corn, beans and squash and many other traits.

The term "Mogollon" signifies the addition of these later traits to the older, basic Cochise culture.

**First Period, 300 B.C.–A.D. 500.**—The first true Mogollon period in which are found pottery, houses, corn, beans, squash and new types of stone tools, dates from about 300 B.C. to about A.D. 500. During that period, the people began to accumulate possessions and therefore had interests to protect—homes, crops, food warehouses and other personal possessions. A feeling of gregariousness seems to have overcome simplicism, and the people increasingly banded together in groups or villages. Villages were not necessarily well laid out; each householder built more or less where he pleased, but within the vaguely defined village limits. Each pit house, however, conformed to a uniform pattern. This pattern demanded that the houses be round and partly below ground and that the food be stored in pits below the floors; also that the houses be supplied with a tunnel side entrance facing east. Often the villages were situated on high, narrow, defensible mesas. Each house was probably occupied by several families related by blood or marriage.

The Mogollon Indians of the early period probably had religious convictions and dogmas and carried on sacred rites in specially built, large pit houses, called kivas.

The Mogollon civilization, therefore, at its inception (about 300 B.C.), may be described as undeveloped but developing, rural and somewhat isolated, although limited contacts with other groups may be conjectured. The Mogollon people of that time, crude and primitive in many ways, had already overcome many obstacles on their uphill journey toward civilization.

**Second Period, c. A.D. 500–900.**—The next major period constitutes a span of about 400 years (*c.* A.D. 500–900), when slow but progressive changes occurred. Apparently fear of enemies had disappeared, for larger villages were built near streams or springs rather than on mesas. Round pit houses were replaced by smaller, rectangular buildings. These homes probably housed only the mother, father and offspring. Cooking was done in fire pits within the house, and food was stored on the floor in basketry and pottery containers. New and more efficient stone tools were adopted, and the spear was replaced by the more accurate and potent bow and arrow. During that period religious services were probably held both in the home and in the kivas. Great advancement took place in the arts as reflected in pottery, basketry, sandals and textiles.

Shortly after the year 500 the Mogollon potters began to decorate their pottery. The first designs were executed with red paint on a brown background. The designs became so complex and were so competently executed that they have been praised by modern ceramists. Basketry and sandals were better woven, and cotton cloth bearing woven designs in colour came into being.

Thus advances were made in the arts, architecture, handicrafts and domestic economy, and the population increased.

**Third Period, c. A.D. 900–1250.**—The third and last period began about A.D. 900 or 950 and ended about A.D. 1250. Profound changes occurred: pit houses were replaced by surface apartment houses from one to three stories in height, with masonry walls; the red-on-brown ware was supplanted by a pottery decorated with black paint on a white background. These traits plus some others were probably introduced to the area by Pueblo Indian migrants whose homeland was in northern New Mexico (*see* PUEBLO INDIANS). There is ample evidence that these newcomers lived peacefully with the older inhabitants of the area in the same villages. Although there was a peaceful penetration by other peoples and some new ideas were introduced, many of the older Mogollon traits continued to flourish. This was, therefore, an early example of cultural intermixture (acculturation).

Finally, about 1250, the Mogollon culture, which had flourished for about 4,000 years (including the early Cochise manifestation as well as the later hybrid), came to an end in the original homeland. The houses and villages were abandoned and the people gradually straggled off—perhaps northward or westward—to make new homes. Various reasons for this exodus have been advanced—war, pestilence, soil exhaustion, change of climate; by the 1960s, however, none of these hypotheses had gained wide acceptance.

**MOGUL,** or MUGHAL, the Arabic and Persian form of the word Mongol. It is inaccurately used to describe the dynasty of emperors of India founded by Babur (*q.v.*) in A.D. 1526. On the male side Babur reckoned his descent from Timur, who was a Barlas Turk; through his mother he was descended from Jagatai, the second son of the Mongol ruler Genghis Khan. It is therefore more correct to refer to the Mogul empire in India as a Timurid or Turki empire.

*See* INDIA-PAKISTAN, SUBCONTINENT OF: *History; see* also references under "Mogul" in the Index. (C. C. D.)

**MOHAIR,** the main specialty hair fibre, forms the long lustrous coat or covering of the Angora goat which originated in Asia Minor. World production of mohair is approximately 50,000,000 lb. annually, with Turkey and the United States supplying approximately 40% each and South Africa the rest. The goat owes its name to the province of Angora in Turkey, where it has been cultivated for thousands of years.

Until the early part of the 19th century it was limited to that country, and the best mohair continues to come from the regions around the cities of Afyonkarahisar, Eskisehir, Ankara and Beypazar. In 1836 Angora goats were first imported into South Africa and are raised primarily in the Karoo region of the Eastern Cape Province. The United States mohair industry was started in 1849 and had its greatest development in the range areas, particularly in Texas and New Mexico.

The colour of most Angoras is white; dark or coloured fibres are undesirable. The production of mohair per goat ranges from 3½ to 7 lb. annually. Much of the mohair is taken off in two clips per year; the length of the fibre ranges from 4 to 6 in. for a half year's growth and from 8 to 12 in. for a full year's growth. The size of the fibre is comparable to that of coarse wool; the finest kid mohair has an average diameter of 25 microns and the adult hair averages between 30 to 40 microns. (Wool fibres range from 10 to 70 microns.) In its microscopic structure the mohair fibre is similar to wool. The epidermal scales are only faintly visible and hardly overlap. The number of scales per 100 microns is 5, as compared to 10 to 11 in fine wools. This scale formation is the cause of the smooth handle of the fibre as well as the high lustre.

Mohair is mainly used as an apparel fibre, being very popular in men's summer suitings in numerous combinations with other fibres and in women's wear coatings such as velours, fleeces and boucles and worsteds. Because of its lustre and because it dyes brilliantly and retains colour well, mohair fibre serves admirably for nets, laces and drapery materials and produces many novel effects in decorative trimmings for coats, hats and shoes. Long-fibre mohair is also used extensively for theatrical wigs and switches. (W. v. B.)

**MOHAMMED** (more correctly, MUHAMMAD) (*c.* 570–632), founder of Islam (*q.v.*), the Muslim religion, was born in Mecca. According to Arab terminology referring to the genealogy or clan, the full form of his name is ABULQASIM MOHAMMED IBN 'ABDULLAH IBN 'ABD AL-MUTTALIB IBN HASHIM.

**Significance of His Personality.**—Few men have exercised so deep and lasting an influence as Mohammed: a religious influence, first and foremost, since the teaching handed down by Mohammed remains a living faith and a doctrine observed by nearly one-seventh of the world's population; a historical influence too, since, in less than 20 years, the movement he started had shaken two great powers, the Byzantine empire and the Sassanid empire in Persia, founding a new civilization, a political and social influence as well, since Islam as preached by Mohammed is both a religion and a system for the organization of the community. Moreover, after the death of Mohammed a whole system of traditional teaching was developed, presenting his behaviour in the various circumstances of life as a model for the faithful, so that the influence of Mohammed's personality was reflected in the everyday conduct and outlook of succeeding generations of Muslims (*see* HADITH).

But though it is impossible to overestimate Mohammed's historical importance, it is necessary, in a quite different sense, to emphasize the fact that his position in the actual doctrine of Islam—at least in its orthodox form—is a comparatively modest one. For one of the basic tenets of Islam is that the Koran (*q.v.*) is a divine revelation of which Mohammed was simply the vehicle. Therefore, according to the strict doctrine, Mohammed has no supernatural quality. "I am not an innovator among the apostles. I am only following what has been revealed to me and I give sin-

cere warnings" (Koran xlvi, 9). But Mohammed is not the author of the Koran; any orthodox Muslim would regard such a suggestion as blasphemous. That is why the Muslims reject the term "Mohammedanism" by which the west often designates their religion. They themselves prefer to call it Islam, meaning "confident submission" (to God).

It was not long, however, before hagiography took over and began to idealize Mohammed's life. In a different way, since the 19th century, the liberal and modernizing reformers of Islam, wishing to humanize their religion and guard against what they considered to be the excessive predominance of its metaphysical or legalistic aspects, have strongly individualized the figure of Mohammed, conferring upon him, even to the risk of sentimentality, a theological position not recognized by orthodoxy. Western critics, however, have sometimes gone too far in the opposite direction. The information derived from historical sources, which deal chiefly with the last 20 years of his life, and the researches of modern scholars suggest a figure rather many-sided but utterly genuine. One of the most remarkable aspects of his biography is, in fact, this often moving contrast between the extent of his achievement and the real humanity of his character.

**Sources for His Life.**—Shortly after Mohammed's death Muslims started to write his life (*sira*), often in an idealized form. The earliest of these biographies have not survived; the chief traditional one, *Kitab sirat Rasul Allah*, by Ibn Hisham, is based on the earlier *sira* by Ibn Ishaq. Most later Islamic historians rely on this work, but the *Kitab al-Maghazi* by al-Waqidi and the *Kitab al-Tabaqat al-Kabir* of Ibn Sa'd are also important. All date from the 8th–9th centuries.

The most important historical source, however, for Mohammed's life is the Koran itself, giving the very words that he uttered as a revelation and that were collected in his lifetime. The final text was established as early as *c.* 650 and has not been altered since. The *hadith*, reporting the sayings of Mohammed in various circumstances as told by "chains of authorities" and collected by traditionists, are less reliable, as a number of them have been interpolated in the course of history; those that have earned the greatest regard are by al-Bukhari and Muslim ibn al-Hajjaj, both of the 9th century.

Reference to Arabia in contemporary non-Arabian chronicles is disappointingly rare. Inscriptions and written sources relating to the period have been little studied, but there are allusions, sometimes revealing, in contemporary poetry.

**His Youth.**—The posthumous son of 'Abdullah, a member of the prominent Meccan family of Hashem (Hashim), a subdivision of the Qoraish (Koreish) clan, Mohammed lost his mother when he was six years old. The orphan was taken care of first by his grandfather, 'Abd al-Muttalib, and later by his paternal uncle, Abu Talib. But the Hashemites had suffered serious reverses of fortune, so that their influence had declined. Entrusted to a Bedouin nurse, Halima, the child Mohammed must then have spent his early years in poverty as a shepherd boy, living the existence of the nomads in the mountainous regions near Mecca. Later he accompanied some of the caravans, first probably those of his uncle Abu Talib, which the Meccan tradesmen organized regularly, northward into Syria or south toward Yemen. In his trading expeditions he showed himself both successful and honest, qualities that caused a widow, Khadija, to entrust him with the management of her business affairs. At the age of 25 Mohammed married Khadija, and the marriage, which lasted until her death 20 years later, was a particularly happy one. Many years older than her husband, she was his truest confidant, the first to believe in him and the first convert to Islam.

Thus, until the age of about 40, when he started preaching, Mohammed lived a peaceful life and attained relative prosperity. Indeed, in a town racked by commercial speculations, in a world where every Arab had taken part in some armed fighting, the life of Mohammed might have appeared unusually quiet and uneventful. In a climate where men grow old early, he was already past the age of adventure and ambition. Suddenly, his whole existence changed; a new phase of his life began.

**Mohammed Begins to Preach.**—About the year 610 Mohammed had formed the habit of withdrawing periodically into the mountains near Mecca to meditate and pray. One night on Mt. Hira, according to the tradition, he had an overwhelming spiritual experience; the word of God was revealed to him by the archangel Gabriel. Mohammed himself related that he heard an imperious voice and that a luminous being grasped him by the throat and commanded him to repeat the sacred words. At first, he tried to flee; Khadija later described his doubts, his self-questioning as to the genuineness of his message, his dread of resembling the visionary poets to be seen in the markets at Mecca with their pretense of being possessed. Then came a period of inner emptiness when "the revelation was silent," and his distress was even greater. Finally he was again seized by the conviction that he had a message to convey. His hesitation ceased, and around 613 he began his preaching. This took the form of a rhythmical recitative packed with exhortations and vivid comparisons. In content it was a fervent and reiterated proclamation of the all-powerfulness of the one God, Creator of the universe, who would summon all his creatures into his presence for judgment on the day of resurrection. But this God of justice was a God of mercy too. He had filled the earth with the signs of his glory and grace. Every man was morally responsible to him for the conduct of his own life. Every man must respond to the divine love and blessings by faith, prayer and charity. Mohammed did not preach this as a new doctrine. He declared that his teachings formed part of the prophetic tradition. He constantly reminded his listeners of the apostles of monotheism, such as Abraham, Moses and Jesus, who had been sent in earlier times with the same message. Their "reminders" and "warnings," as the Koran calls them, were now being repeated, in Arabic, owing to the revelation made to Mohammed.

**Reaction at Mecca.**—There was no immediate opposition. During the first few years, indeed, Mohammed spoke only to a small, intimate group of his family and friends. The hostile reaction of Mecca arose gradually as he began preaching to a wider circle and was probably due in great part to economic considerations. For it is a mistake to suppose, as was done for a long time, that Islam originated among nomads of the desert. Islam took shape in a town, a town characterized by an avid interest in trade and finance. Mecca stood in a rocky valley with no agricultural resources, and all its profits came from trading. The temple had become a place of profitable pilgrimages, accompanied by fairs and markets. A mercantile republic had thus grown up—an oligarchy governed by a council which included the richest traders.

Mohammed's preaching was a frontal attack on this system. Opposition to him at first took the form of mockery and interminable polemics. Then came persecution, which developed to such an extent that in 615 he advised the most vulnerable of his followers to take refuge in the Christian land of Ethiopia. Membership of the Hashemite clan, which had so far afforded some protection to Mohammed in his immediate entourage, was no longer effective. Matrimonial or commercial relations with the clan were forbidden. With these political trials came personal sorrows. In 619, "the year of mourning," both Khadija and Abu Talib died. Mohammed then began to seek refuge outside Mecca. Help came from Yathrib, which after its hospitality to Mohammed was renamed "Madinat an Nabi," the city of the Prophet, Medina.

**The Medina Period.**—Unlike Mecca, Yathrib was not a trading centre but an oasis, where an agricultural community lived by cultivating date palms. Two hostile tribes, the Aws and the Khazraj, were vying for precedence. The population also included three Jewish tribes. Tension between the two parties had reached a pitch where it seemed that only arbitration by someone unconnected with the conflicting clans could dispel it. Mohammed, as the head of a community whose principle was to transcend tribal divisions, was fitted to be the arbiter. Moreover, the presence of considerable Jewish settlements at Yathrib might have encouraged the Prophet to hope that his monotheistic doctrines would find a better reception there.

The first negotiations, conducted in secret, culminated in 622 in an agreement known as the pact of Aqaba, by which the new disciples took an oath of fidelity. In small groups the Muslims began to settle at Yathrib. The Meccans, alarmed, decided to

strike at the leader. They plotted to assassinate Mohammed, who was still in Mecca almost alone. But he managed to escape during the night and, after hiding for a time on Mt. Thaur, reached Yathrib on Sept. 24. Thus began the hegira (*q.v.*) or emigration. The Muslims reckon their era from this year, starting July 16, 622. In that year Islam found its form, asserting itself not only as a religion but also as an organized community.

The date also marks a turning point in the life of Mohammed. The preacher now became a politician and a ruler and before long a military leader as well. The text of a charter that forms the first constitution of Islam has been preserved. It shows remarkable political insight. Thus, one of the first measures was to integrate the refugees from Mecca with the original population of Medina. For this purpose, Mohammed instituted legal bonds of brotherhood between each immigrant and one of the Ansar ("assistants," "helpers"), as the hosts at Medina were now called. So religious unity did not prevent recourse to the already existing Arab custom of brotherhood. The two principles reinforced each other.

Mohammed also set himself to win over the Jews, assuring them of freedom to practise their religion and even including certain of their rites in Islam (such as the custom of turning toward Jerusalem when praying) as a witness to the fundamental unity and permanence of monotheism. In return, the Jews were to accept the new civil authority and contribute to military expenses. These political and economic restrictions appeared irksome to the Jews, who had enjoyed a favourable situation in Yathrib. They also refused to acknowledge Mohammed as a prophet and opposed to him their own biblical writings. Relations became strained. Less than two years after the hegira, Mecca (the sanctuary of the Black Stone) took the place of Jerusalem as the direction in which to pray. Simultaneously the doctrine of original monotheism gained strength—of a monotheism older than Judaism or Christianity, symbolized by Abraham and the temple at Mecca with Islam as its authentic representative.

**Military Campaigns.**—If Mecca was to be the centre of Islam, the exile at Medina could be regarded only as a temporary necessity. Moreover, the Meccans, who controlled the trade of Arabia, were bringing economic pressure to bear on the refugees and their hosts. The *émigrés*, who had lost all their property, were beginning to feel the pinch of poverty. The war began gradually, in the Bedouin manner, with a succession of raids and skirmishes. Reprisals and counterreprisals intensified. The losses on both sides were comparatively slight. But success or failure had far-reaching psychological repercussions on the tribes, which were highly sensitive to gain or loss in prestige. The first considerable victory was won by the Muslims at Badr, in the spring of 624. Despite their inferior numbers, the Muslims' dash carried the day. But the Meccans were bent on avenging their dead and reasserting their impaired authority. A year after Badr, an army of 3,000 men advanced upon Medina. The Muslims made an ill-judged sortie and were defeated at Ohod, largely through lack of discipline. Mohammed himself was wounded.

However, the Meccans were incapable of following up their victory. Not until March 627, when they had persuaded a number of Bedouin tribes to join their cause, did they bring a strong force against Medina again. Mohammed then resorted to tactics which were unfamiliar to the Arabs, accustomed to brief, isolated raids. Avoiding the mistake made at Ohod, he did not sally out to meet the enemy in the usual way but had a ditch dug around Medina. The Meccan horsemen were disconcerted and bored. The coalition started breaking up. Bad weather added to the discouragement of the besieging force, and it finally dispersed.

**Pact of Hudaibiya and Return to Mecca.**—The "battle of the ditch" had restored the initiative to Mohammed. He used it, however, chiefly as a means to negotiation. The opposing forces were now more equally matched and the Meccans were tired of a war that was damaging their trade. They were further appeased by Mohammed's declared intention of not merely respecting the traditional pilgrimage but making it one of the basic rites of the new religion. After various overtures, including the resumption of trade between the two cities, Mohammed secured a truce to enable himself and his companions to undertake their pilgrimage. They set out on their peaceful march, but as they drew near the city their way was barred by an armed group. The Muslims stopped and camped at Hudaibiya, where a Meccan delegation came to parley. As a result of these negotiations Mohammed agreed to three conditions: the Muslims would return to Medina without visiting the temple at Mecca and would return the following year for a visit not to exceed three days; Meccans who emigrated to Medina would be extradited on request; and there would be a ten-years' truce during which each party should be free to cross the other's territory and remain neutral in the event of either's becoming involved in war with a third party.

This agreement, known as the pact of Hudaibiya, made concessions that many of Mohammed's companions found exaggerated and that gave rise to violent criticism. But it proved successful. It obliged the Meccans to give official recognition to a group of fugitives they had despised and to accept them as entitled to conduct negotiations with the chief city of Arabia. It also gave Mohammed time to establish his position at Medina once and for all.

The agreed pilgrimage, which took place in 629, found Mecca almost deserted, for the inhabitants had withdrawn to the neighbouring hills. Once their pious purpose had been fulfilled, the Muslims departed, as required by the treaty. This display of strength combined with moderation impressed the Meccans. The time was ripe for a solution. An opportunity arose when a quarrel flared up between two tribes and Mecca unwisely gave its support to one of them, thus breaking the pact of neutrality. At once, in Jan. 630, the Muslims were ordered to advance on Mecca. The city capitulated almost without a blow and nearly all the inhabitants accepted Islam. Thus the patience, the risks accepted, the restraint imposed on followers throughout the preceding years of negotiations at last bore fruit.

The same moderation prevailed in the hour of victory. Mohammed made a ceremonial entry into the temple and ordered all the idols to be overthrown and the building to be converted from a pagan shrine into a Muslim sanctuary. But apart from this symbolic act he was careful not to offend the population. By a general amnesty and other evidence of liberality, Mohammed succeeded, indeed, in gaining the lasting support of his former enemies.

**Relations With Judaism and Christianity.**—Established in its spiritual capital, Islam gradually took shape as a religion distinct from Judaism and Christianity. True, the Prophet's preaching had always stressed the essential unity of the monotheistic creeds, which is proclaimed in many verses of the Koran: "God has ordained for you the religion he commended unto Noah and which we have revealed to thee and we commended unto Abraham and Moses and Jesus" (xlii, 13). And to the "people of the Scriptures" or "book" the Muslims are told to say "We have faith in that which has been revealed to us and in that which has been revealed unto you. Our God and your God are one, and unto him we are resigned" (xxix, 46). But from the early days at Medina, despite all appeals to the Torah and to the name of Moses, the Jews had shown themselves reserved. Reluctant to change their manner of life, they were more inclined to favour the Meccans. However, they proved unable to unite against Mohammed, so that in the intervals of his campaigning outside Medina he was able to crush their sporadic moves within the city. Several of their groups were banished. After the pact of Hudaibiya had given him security from the Meccans, he struck his most severe blow, capturing (628) the important oasis settlement of Khaibar, populated entirely by Jews.

Relations with the Christians remained more satisfactory. The Koran declares that "Those who are most disposed to friendship with the faithful [*i.e.*, the Muslims] are they who call themselves Christians; this is because they have priests and monks, and because they are free from pride" (v, 85). While the community was struggling to survive and organize itself, it did not have to take account of the Christians, who were few at Mecca and Medina. But, as Islam spread and contacts with Christian communities developed, differences of doctrine were shown to be so fundamental and profound as to make a division inevitable in the long run. This became manifest, for instance, in 631 during the episode known as the Najran meeting. Theological discussions

with a deputation from Najran, a fertile valley in Yemen, inhabited by one of the largest Christian communities in Arabia, broke down over the dogma of the incarnation of Christ. Despite this failure, however, Mohammed had part of the mosque set aside for the Christians to perform their rites.

**Government From Mecca; the Last Years.**—The period 630–631 was not only that of various embassies sent to Mohammed. It was also marked by military expeditions, with which the Muslim state initiated its expansion. Around 630–631, Mohammed's authority was firmly established and the unification of the Arabian peninsula proceeded steadily. Mohammed thereupon reorganized his administration. Almsgiving was transformed into a government tax at fixed rates. Religious connections had now been permanently substituted for the system of clans and tribes. Paganism was outlawed. The Muslim community was based on the principle of equality and governed entirely by the koranic law. The verses of the Koran dating from this period are no longer cast in the breathless rhythm of the Meccan phase. Their style is calmer and they deal chiefly with the structure of society. The former social system had been particularly unfavourable to women; the new laws entitled them, for example, to own property and to inherit it. The husband's obligations were defined for the first time, and the legal maximum number of wives was reduced to four.

In considering the status of women in Islam, it is only fair to remember the position they had previously occupied in Arabia. Western critics have often reproached Mohammed for his own polygamy. Here again we should bear in mind the life led by the Arab tribal chiefs. As long as Khadija was alive, Mohammed remained unswervingly faithful to her. Among his later wives there were two of whom he seems to have been especially fond—'A'isha (*q.v.*), his favourite, whom he married as a very young girl, after the battle of Badr, and Zainab. Their personalities were not without influence on the life of the community. Only Mohammed's female offspring, all by his first marriage, survived. One of his daughters, Fatima (*q.v.*), married 'Ali (*q.v.*), Mohammed's first cousin and one of his earliest converts. There were two children of this marriage, Hasan and Husain (*q.v.*). If matters had been settled by right of birth, these should have succeeded to the Prophet's position. But the elective system was adopted, and the dispute over the succession caused the first and only major schism in Islam's history.

As early as the pilgrimage of 631, Mohammed had designated one of his earliest companions, Abu Bakr (*q.v.*), to preside over the ceremonies. In the following year Mohammed himself led the pilgrimage. He had by then begun to feel the effects of the malady to which he later succumbed, and this ceremony, known as the "farewell pilgrimage," served as a final recapitulation, a collective scrutiny of his lifework by both himself and the community. Tradition has preserved the moving terms of this farewell. In his last sermon he urged his followers not to split up after his death, affirmed yet again the unity of God and the brotherhood of the faithful, enjoined the community to watch over the rights of women and proclaimed the abolition of blood feuds and of usury. Then he returned to Medina and died there on June 8, 632. Tradition says that Abu Bakr, the newly elected *khalifah* (caliph, successor), said to the sorrowing faithful: "If you are worshipers of Mohammed, know that he is dead. If you are worshipers of God, know that God is living and does not die." Thus Mohammed's life ended as his preaching had begun, in the absolute devotion, amounting to self-effacement, of the man to the mission.

Mohammed's biographers have tended to make a sharp division between his two periods of activity—as the prophet and preacher of Mecca and as the politician and lawgiver of Medina. Critics of the 20th century, however, tend to modify this distinction, which seems to have no psychological or historical justification. The balance, the composure and the grasp of possibilities so often displayed by Mohammed at Medina would be unaccountable if the apostle of Mecca were no more than a passionate being in the throes of inspiration. Inspired he was, but he had foresight too. Yet the inner tension that set him to preaching never really subsided. There is ample evidence that Mohammed's main influence was not through any doctrinaire theological teaching but through stimulating leadership and a moral ascendancy over those who came within his range. His own stimulus throughout his career came from religion. His life derived its unity from faith.

**MOHAMMED V** (SIDI MOHAMMED BEN YUSUF) (1909–1961), sultan of Morocco from 1927 to 1957 and king from 1957 to his death, fifth ruler of the Filali (*q.v.*) dynasty to bear the name Mohammed, was born at Fès (Fez) on Aug. 10, 1909, the third son of Sultan Mulay Yusuf. On his father's death in 1927, the 18-year-old prince was chosen by the French authorities as sultan in preference to his two elder brothers. Within ten years his intelligence, capacity for work and diplomatic skill had marked him out as the outstanding personality in the country. Though conditions did not permit his governing, he set himself to encourage popular education, giving the example by providing excellent French as well as Arabic instruction for his children. During World War II Mohammed V continued to co-operate after the collapse of France, but refused to sanction the introduction of Vichy anti-Jewish legislation or to follow Gen. Auguste Nogues in 1942 in organizing resistance to the Allied landings. He was encouraged by personal contact with western leaders, and when, in 1944, the Istiqlal party put forward a demand for independence he let his sympathy for the nationalists appear. The next landmark was his visit to Tangier in 1947. In his speech in the international city he ignored France but stressed the affinities of Morocco with the eastern Arab states. The French government thereupon appointed Gen. Alphonse Juin as resident general, with authority to apply strong measures. In 1951 the latter, unable to impose his will on the sultan, mobilized the Berber tribesmen against him, but failed to extort more than a partial disavowal of the Istiqlal. Two years later, the new resident general, Gen. Augustin Guillaume, adopting a similar policy, deported the sultan first to Corsica, then to Madagascar. An elderly nonentity was appointed to succeed him. The result was a great increase in the deposed ruler's popularity, an outbreak of terrorism and, finally, fighting in the Rif.

In 1955 the French government yielded and the sultan made a triumphal return. Henceforth, he had the responsibility of ruling, as well as reigning over, a country faced with great political, economic and social problems. Consistently moderate, he directed his people toward a distant goal of constitutional government, while seeking to maintain good relations with the west. In 1957 he changed his style from sultan to king, and later secured the recognition of his eldest son, Prince Maulay Hassan, as his successor. He died very suddenly at Rabat on Feb. 26, 1961. *See* also MOROCCO: *History*. (N. BA.)

**MOHAMMED I** (d. 1421), Ottoman sultan of Turkey from 1413 to 1421, was the youngest son of Bayazid I. After the battle of Ankara in 1402, Timur (*q.v.*), victorious over the Ottomans, restored to their lands the Turkish begs of Asia Minor whom Bayazid I had evicted. He also left the Ottoman territories in a state of dismemberment. Of the sons of Bayazid I, Mohammed was ruling at Amasya, Isa at Bursa and Suleiman in Rumelia (Rumeli), *i.e.*, the Balkan lands under Ottoman control. Mohammed seized Bursa not long after 1403 and then became engaged

in a conflict with Suleiman. He sent to Rumelia his brother Musa, who defeated Suleiman in 1410, but, attempting to rule alone in Rumelia, was himself crushed by Mohammed in 1413 at Camurlu in Serbia. The events of the years 1402–13 demonstrated that the idea of an Ottoman state in Rumelia distinct and separate from the Muslim territories in Asia Minor, which Suleiman and Musa had striven to realize, was not viable. Mohammed, during his brief reign as sultan, re-established Ottoman control over much of western Asia Minor. He overcame a great religious revolt which broke out there in 1416 under Sheikh Badr al-Din and also had to face a new threat from a pretender who claimed to be his brother Mustafa, missing since the battle of Ankara in 1402. Mohammed died at Edirne in 1421.

**MOHAMMED II** (1432–1481), Ottoman sultan of Turkey from 1451 to 1481, known as Fatih ("the conqueror"), was born at Edirne, Turk., on March 30, 1432. He had been called to the throne in 1444 when his father, Murad II, went into temporary retirement at Manisa (Magnesia) in western Asia Minor. Sultan Murad, in view of the fact that grave problems then confronted the Ottoman state and under pressure from the great dignitaries of the Porte, was soon, however, to reassume control of Ottoman affairs. Mohammed became sultan once more on the death of his father in 1451. He strove throughout his reign to realize one main purpose: the consolidation of the Ottoman state. Constantinople fell to him in 1453. (*See* ISTANBUL: *History*.) Mohammed repaired the walls, erected new public buildings and repopulated the town with groups of Muslims, Christians and Jews drawn from the provinces of the empire. He thus began the long process that was to transform Constantinople into Istanbul, a proud capital reflecting in itself the rich and varied character of the Ottoman state.

Consolidation was also the aim of the numerous campaigns that Mohammed carried out in the course of his reign. All that was left of an independent Serbia became in 1459 the Ottoman frontier province of Semendria (Smederevo) over against the Hungarian fortress of Belgrade, which the sultan had attempted to capture, but without success, in 1456. Bosnia was overrun in 1463–64; most of the Bosnian nobles then embraced Islam and had henceforward a great role as warriors of the Muslim faith engaged in constant warfare against the neighbouring Christian lands. Athens and almost all the Morea came under Ottoman rule in 1458–60. Sultan Mohammed fought a long war with Venice during 1463–79, as a result of which the Ottomans acquired Negroponte in 1470 and strengthened their position on the Adriatic shore through the conquest of Croia (Krugë) and of Scutari in 1478–79.

Mohammed also made an end of the Genoese imperium in the area of the Black sea. Amastris and Sinope (Sinop), centres of Genoese trade, together with the Greek state of Trebizond (Trabzon), yielded to the sultan in 1461. The Ottoman fleet, in 1475, seized Kaffa (Feodosiya), a Genoese emporium in the Crimea. At the same time the khan of the Krim Tatars became a vassal of the sultan. Meanwhile, in 1466, Karaman, a Turkish emirate in Asia Minor long hostile toward the Ottomans, was at last absorbed into the territories of the sultan. An attempt, made in 1480, to capture the island of Rhodes from the Knights of St. John of Jerusalem ended, however, in failure.

Mohammed II was a patron of the arts and of learning. His law code (Qanun-name) defined some of the basic institutions and usages of the Ottoman state. The sultan died at Tekfur Cayiri, near Gebze, on May 3, 1481, on the eve of a new campaign in the east. *See* also TURKEY: *History*.

**MOHAMMED III** (1566–1603), Ottoman sultan of Turkey from 1595 to 1603, was born at Manisa in the summer of 1566. Throughout his reign a bitter conflict was in progress with Austria. An Ottoman attempt to regain control of the lower Danube met with disaster in 1595. The same year saw, in addition, the Christian capture of Gran (Esztergom), the northernmost bulwark of Ottoman power in Hungary. Sultan Mohammed himself shared in the campaign of 1596, which led to the Ottoman conquest of Erlau (Eger) and to a severe defeat of the Christians at the battle of Mezö-Keresztes. There followed a stubborn war of sieges, in the course of which the Ottomans took the great fortress of Kanizsa in 1600. The last years of the reign witnessed the outbreak of serious revolts in Asia Minor and also the beginning of a new war with Persia. Mohammed III died at Istanbul on Dec. 22, 1603. *See* also TURKEY: *History*.

**MOHAMMED IV** (1642–1693), surnamed Avji ("huntsman"), Ottoman sultan of Turkey from 1648 to 1687, was born in Istanbul on Jan. 2, 1642. He succeeded his father Ibrahim I on Aug. 8, 1648, at the age of six, being the only Ottoman prince left alive. Until 1656 power was in the hands of harem factions; from that year onward it rested with a series of grand viziers, beginning with the two great Koprulus. The sultan was not devoid of spirit; he took part in several campaigns, notably those of 1663 and 1672, against Austria and Poland, respectively. He preferred, however, to devote his energies to hunting. No minister ever succeeded in curbing his enormous expenditure on this occupation. The disastrous defeat of the Turks at Mohacs in Hungary (1687) cost Mohammed his throne. Deposed in November of the same year by a revolt of the army supported by the ulemas, he spent the last three years of his life in retirement at Adrianople (Edirne), where he died on Jan. 7, 1693. (G. L. L.; E. Z. K.)

**MOHAMMED V** (1844–1918), Ottoman sultan of Turkey from 1909 to 1918, known as Reshid, was born on Nov. 3, 1844, at Topkapi. He was the son of Sultan Abdul-Mejid and a younger brother of Abdul-Hamid II. He became sultan when Abdul-Hamid was forced to abdicate in 1909. All his life he lived under close supervision at the palace. He was kind and gentle but very simple and weak. Although he did not have the ability to govern in difficult times, he never acted with cruelty. During the nine years of his reign he obeyed the wishes of the Committee of Union and Progress, went on a tour of Thrace at their suggestion and visited Albania, trying to convince the rebels there to give up their struggle. His reign is marked by the absolute rule of the Committee of Union and Progress and by the final downfall of the Ottoman empire. He is credited with having been opposed to the pro-German policy of Enver Pasha but if so, he was unable to take any effective measures against it. Having already seen in his short reign the loss to the Ottoman empire of much of the Balkans and Tripoli, he lived through the defeat of Turkey in World War I and died at Yildiz on July 2, 1918. *See* also TURKEY: *History*. (M. P. P.)

**MOHAMMED VI** (1861–1926), known as Vahid-ed-Din, 36th and last of the Ottoman sultans of Turkey (1918–22), was born on Jan. 14, 1861. He became sultan in 1918, at the age of 57, on the death of his brother Mohammed V. All his life he had lived as a prisoner in the palace. He had the cunning but not the intelligence of his elder brother Abdul-Hamid II. During his four-year reign as sultan, the intrigues he indulged in for his personal safety earned him the nickname of the "black sultan." He accepted the treaty of Sèvres (1920) and did his best to suppress the nationalist forces which were fighting for Turkish independence. Finally on Nov. 17, 1922, after the defeat of the Greeks by the nationalist forces, he escaped on a British warship. Later he tried unsuccessfully to set himself up as caliph in the Hejaz. He died at San Remo, Italy, on May 16, 1926. *See* also TURKEY: *History*. (M. P. P.)

**MOHAMMED** OF GHOR OR GHORI (MU'IZZ UD-DIN MOHAMMED IBN SAM) (d. 1206), Ghorid conqueror of the north Indian plain. Mohammed Ghori was the half nephew of Qutb ud-Din and the nephew of Saif ud-Din Suri, the slaying of whom by Bahram Shah of Ghazni in 1149 was revenged by the burning of Ghazni by 'Ala ud-Din Jahansuz in 1151. Subsequent to the latter's death, Ghiyath ud-Din, elder brother of Mohammed, acquired power at Firuz Kuh east of Herat in the region of Ghor (*c.* 1162). Mohammed Ghori always remained his loyal subordinate. Thus Mohammed expelled the Ghuzz-Turkoman nomads from Ghazni in 1173 and came as required to his brother's assistance in his

contest with Khwarizm for the lordship of Khurasan. After Ghiyath ud-Din's death in 1202, the rivalry between the two powers came to a head with Mohammed's direct attack in 1204 on the Khwarizmian capital Gurganj and his repulse and defeat at Andhkhud. In Hindustan, Mohammed enjoyed greater success, capturing Multan and Uch in 1175, annexing the Ghaznavid rump principality of Lahore in 1186 and winning the important battles of Tara'in (1192) and Chandwar (1194). He mostly left the rounding out of his Indian conquests to Qutb ud-Din Aibak (*q.v.*). Mohammed Ghori was assassinated on March 15, 1206, at Damyak on the Indus, according to some by Hindu Khokars, according to others by Isma'ilis. Within ten years of his death, Ghor was in the hands of the Khwarizmshah and only his Indian conquests remained. The career of Mohammed Ghori, no outstanding general or statesman, emphasizes the weakness at the end of the 12th century of the Rajput principalities of northern India against a military power in possession of the "Afghan" highlands and of a bridgehead, in the shape of Ghaznavid Lahore, across the Indus. *See* also GHOR.

**MOHAMMED AHMED** (called THE MAHDI; in full MOHAMMED AHMED IBN AL-SAYYID ABDULLAH) (1844–1885), founder of the mahdist movement in the Sudan, was born on Labab Island, Dongola district, Sudan, on Aug. 12, 1844, of a family that claimed descent from the Prophet. His father, a boatbuilder, later brought his family to settle at Karari near Khartoum. Mohammed Ahmed early revealed an aptitude for religious studies and, after frequenting teachers in the Gezira and at Berber, he sought the ascetic life in a religious confraternity. In 1861 he entered the Sammaniyya order but became disappointed at the worldly life of its local head, who, when the young man reproved him, expelled him from his lodge of the order. He then professed allegiance to a rival Sammani leader, and in course of time gathered his own disciples at a hermitage which he had made for himself at Aba Island on the White Nile. During 1880–81 consciousness of his divine election came upon him. In March 1881 he disclosed his mission to his adherents, and on June 29 he publicly assumed the title of the expected Mahdi, calling for the purification of Islam and the destruction of unbelievers, among whom he stigmatized the Turco-Egyptian government. He appointed four caliphs to be the living successors of the four earliest caliphs in Muslim history. Three responded: 'Abdullahi ibn Mohammed (the Khalifa 'Abdullahi), 'Ali ibn Mohammed Hilu and Mohammed Sharif ibn Hamid. The fourth, Mohammed al-Mahdi ibn al-Sanusi, head of the Senusi order at Jaghbub (Giarabub), ignored the invitation.

After a fracas at Aba with troops sent to arrest him, the Mahdi led his followers to Jabal Qadir in the Nuba mountains. There, on Dec. 9, 1881, and on May 30, 1882, he destroyed two Egyptian armies; then, descending from the hills, he laid siege to Bara and El Obeid. Bara capitulated on Jan. 6, 1883; El Obeid, after a hard siege, on Jan. 19. An Egyptian army under Gen. William Hicks advancing from the White Nile to recapture El Obeid was overwhelmed at Shaykan on Nov. 5, 1883. This spectacular victory isolated the garrisons of Darfur and the Bahr El Ghazal, and enormously increased the Mahdi's prestige. By this time Khartoum was in danger. Maj. Gen. C. G. Gordon (*q.v.*) reached the capital on Feb. 18, 1884. He had written to the Mahdi offering him the sultanship of Kordofan, but the offer was contemptuously declined. In early September the mahdist vanguard approached the suburbs; the Mahdi with reinforcements arrived on Oct. 23 and set up his headquarters at Abu Sa'd on the White Nile near the city. Khartoum fell on Jan. 26, 1885, and on Jan. 30, when the massacre of the citizens was over, the Mahdi made a triumphal entry and led the Friday prayers in the town mosque. He died in Omdurman on June 22, 1885, probably of typhus, and was buried under the dome which is a prominent feature of the town. Omdurman, the Mahdi's military headquarters, then became the capital of a new state that stretched from Nubia to the equatorial regions and from Darfur to the Red sea, the structure of which was a conscious copy of the polity of primitive Islam. The Mahdi referred to himself as the "successor to the apostle of God," *i.e.*, successor to the Prophet (*see* MAHDI), and directed the movement by proclamations, warnings and directives covering the entire field of theology, law, sociology and economics. The mahdist movement, which is still a powerful force in the Sudan, continues under the leadership of the Mahdi's descendants.

**MOHAMMED ALI** (1769–1849), also known as Mohammed Ali Pasha, Ottoman viceroy (vali) of Egypt from 1805 to 1848 and founder of the dynasty that ruled Egypt until 1952. His origin has been much disputed. Most European writers, on the strength of his association with Albanian troops, have concluded that he was himself an Albanian. According to the family tradition his ancestors were Turks from Arapkir in Anatolia who afterward settled in Konya. From there his grandfather emigrated to Kavalla on the Aegean coast of Macedonia where the future viceroy was born (1769). He was one of 17 children of Ibrahim Agha, head of the local town watchmen. Here he married a wife who gave him five of his numerous children. As a young man he entered the tobacco trade, an occupation which, by bringing him into contact with the sharpest wits among the Greek and European commercial communities, introduced him to a wider world than was normally open to a Turk, and probably explains his ability to understand and live on easy terms with non-Muslims.

When in 1798 Bonaparte with a French army landed in Egypt, Mohammed Ali accompanied a contingent of Macedonian Albanians that was sent with an Ottoman expeditionary force to resist the invaders. On disembarking at Abukir (Abu Qir) the Ottomans were driven back to the sea and Mohammed Ali narrowly escaped from drowning. He survived the defeat and by 1801 had risen to be one of the two officers commanding Albanian formations in Egypt. After the departure of the French in that year Egypt relapsed into anarchy. By the judicious use of force and intrigue, about which he was reluctant to speak in after years, he systematically disposed of his Ottoman and Mameluke rivals for power. In 1805 he won the support of the citizens of Cairo against the undisciplined troops of the governor general, Ahmad Khurshid Pasha, the future imperial grand vizier, who was compelled to relinquish the citadel to Mohammed Ali. The Ottoman government attempted to lure Mohammed Ali from Egypt by offering him, on May 10, 1805, the grade of vizier and the governorship of Jidda. The new vizier announced to the people his elevation to the exalted grade but concealed from them his appointment to Jidda. Three days later the inhabitants publicly acclaimed him as their ruler and repudiated Khurshid. Finally Istanbul, bowing to reality, issued a firman, which arrived in Cairo on July 19, appointing him vali of Egypt in Khurshid's place. On March 23, 1806, Mohammed Ali received a firman of confirmation.

The new vali then embarked upon his long and distinguished term of office. In 1807 he was able to demonstrate his loyalty to Sultan Selim III, who was then at war with Britain, by twice defeating British forces that were supporting a Mameluke faction in the delta. Having delivered Egypt from attack he next set about the elimination of the Mamelukes, his last enemies within the country. In 1808 he persuaded many of the Mameluke beys to settle in and round Cairo where he could supervise their movements. Some refused to give up their armed retainers and were potentially dangerous. These were subdued in a series of small engagements. At this stage Mohammed Ali prepared their complete destruction. Some 300 beys were invited to the citadel to a ceremony of investiture of his son Tusun who was to lead an Egyptian army against the Wahhabi rebels in Arabia. The celebration was held March 1, 1811. No sooner had the guests arrived within the walls of the citadel than the gates were shut and a murderous fire was opened on them, and all but one were killed.

Tusun's campaign, undertaken at the request of Sultan Mahmud II, opened with defeat in 1811 and partial victory in 1812 when the holy places were liberated from the puritanical yoke of the Wahhabis. Mohammed Ali made a tour of inspection in the Hejaz, reorganized the Egyptian forces and replaced the sharif of Mecca whom he suspected of sympathizing with the enemy. In 1814 he took the field after visiting Mecca and gaining the pilgrim's title of *al-hajj*. Tusun proved his incapacity and on his death was succeeded in command by Mohammed Ali's eldest son Ibrahim (*see* IBRAHIM PASHA) who began his military career by breaking the power of the Wahhabi movement by a hard campaign in 1816–18.

In 1820–21 came the Egyptian penetration of the Sudan when two armies sent by Mohammed Ali occupied Sennar and central Kordofan. The commander of the army of Sennar was his third son, Ismail. In Oct. 1822 the killing of Ismail by an aggrieved Sudanese chief at Shendi was the signal for a desperate Sudanese revolt against the Egyptian conquerors. On hearing of his son's death Mohammed Ali vented his rage upon the commander of the region, urging him to massacre all the tribes within range, but, recovering himself, wisely allowed the local authorities to deal with the revolt in their own way.

Mohammed Ali did not regard the Greek insurrection in the Morea (1821–27) as involving the Greek colony in Egypt, which he treated with kindness even while his son Ibrahim was fighting their compatriots on the Greek mainland. Nor was he permanently embittered when the kingdom of the Hellenes was set up (1833). The consul general in Egypt of the new kingdom was his old friend, Michael Tossitza. But when all his services to the Ottoman sultan in Arabia and Greece were countered by what he conceived to be the sultan's ingratitude, he went to the length of declaring war against his imperial master. At the end of 1831 an Egyptian army under Ibrahim Pasha invaded Syria. A succession of victories over the demoralized Ottoman army, which was still in the difficult process of transition from oriental to western organization and training, brought the Egyptian outposts to within 100 mi. of Istanbul. For eight years the Egyptian frontier stood on the crests of the Taurus mountains and the Euphrates, and Syria was united to Egypt as it had been before the Ottoman conquest of 1517. But in 1840 the European powers intervened to protect the sultan who had rashly attacked the Egyptians and had been decisively beaten at Nizib in the preceding June. By virtue of firmans issued on Feb. 13 and June 1, 1841, Mohammed Ali surrendered Crete, Syria and Adana which reverted to the direct control of the Porte, while in compensation the sultan granted Mohammed Ali the hereditary rule of Egypt.

The exacting years of the Egyptian adventure in Syria left the viceroy physically exhausted though mentally serene. He was now an old man. In 1846 he visited Istanbul and made a nostalgic excursion to his native Kavalla where he founded a school. By 1848 senility overtook him. Ibrahim, who had been in virtual control of the administration since 1847, received a firman appointing him to his father's post but the son died on Nov. 10, 1848, leaving the viceroyalty to his nephew Abbas I. Mohammed Ali lingered on until Aug. 2, 1849, when he died at Alexandria.

Mohammed Ali's reputation has been much exposed to the variable winds of historical opinion. In Egypt at various times he has been hailed as a forerunner of Arab nationalism and condemned as a ruthless exploiter of the peasants. Though Lord Palmerston's distrust of him amounted almost to an obsession, European observers in general saw in him a reformer after their own hearts. The French patronized him with justice as a brilliant pupil, for his new Egypt had been built largely by French experts. The new-model army and navy were the work mainly of French instructors. Among the British commercial community he had a good name for straight dealing, and Sir John Bowring, when on a commercial mission for the British government in 1839, reported with critical approval on the Egyptian economy.

His land policy was nevertheless condemned as unjust from the standpoint of western conceptions of legality. For he seized the lands which had belonged to the Mamelukes, and between 1808 and 1814 appropriated most of the remaining land on the ground of neglect by the former owners. This vast act of confiscation injured only the small landowning class; it in no way affected the peasants who continued in their agelong poverty. The land thus acquired was put to better use. Mohammed Ali claimed to have installed 38,000 water wheels in Egypt and several more thousand in the Sudan, cleared derelict irrigation canals and dug new ones. The cultivable area of Egypt was thus increased by at least 100,000 acres. He maintained a state trading monopoly in Egypt and the Sudan which was bitterly criticized by European traders whose own profits were consequently diminished.

France and Britain had maintained consuls in Egypt before the arrival of the French, but it was not until after 1815 that the expanding European community at Alexandria and the growing strategic and economic importance of Egypt led every European state of consequence and the United States to post consuls in the country. Their correspondence gives a lively picture of the viceroy and of the efforts of the consuls to impress, cajole or threaten him. His supple mind was able to detect the underlying purpose behind the euphemistic verbiage of consular approaches. He too had mastered the euphemistic technique: to the British he was a paragon of antislave-trade virtue, to the Sardinians a liberal, to the Porte humble. The most revealing guide to his character is in his portraiture: the stocky figure, inclined in old age to obesity, the commanding face and, above all, the piercing eyes. *See* also EGYPT: *History;* and references under "Mohammed Ali" in the Index.

**MOHAMMEDANISM:** *see* ISLAM. For Mohammedan art, architecture and law, *see* ISLAMIC ARCHITECTURE; ISLAMIC ART; ISLAMIC LAW.

**MOHAMMED REZA PAHLAVI** (1919– ), shah of Iran from 1941, the eldest son of Reza Shah Pahlavi (*q.v.*), was born in Teheran on Oct. 26, 1919. On finishing his preliminary studies in Teheran in 1931, he went to Switzerland to complete his education. Returning to Teheran in 1935 he entered the Officers' Training college there and later obtained a commission in the army. He has always shown a liking for natural science, literature and languages. He is fond of sport and of flying and is a fully qualified pilot.

On March 15, 1939, he married the sister of King Faruk I of Egypt, Princess Fawzieh, by whom he had a daughter, the princess Shahnaz; this marriage was dissolved in 1948. Succeeding to the throne on his father's abdication on Sept. 16, 1941, the new shah began his reign under difficult conditions, with British and Soviet troops (and later those of the United States) in virtual occupation of large areas in the north and southwest of the country.

After the war, the Allied troops were withdrawn and conditions gradually returned to normal. In 1951 the shah married Soraya Esfandiary Bakhtiari. After the appointment of Mohammed Mossadegh (*q.v.*) as prime minister in April 1951 strained relations developed between him and the shah. In Aug. 1953 a military *coup d'état* organized by Gen. Fazlullah Zahedi while the shah was in Europe resulted in the overthrow of Mossadegh and the return of the shah to Iran.

Mohammed Reza Shah has always endeavoured to rule as a constitutional monarch. His achievements in the fields of education, communications, land ownership, social welfare and public health have been far-reaching and of great value. In Dec. 1959, his union with Queen Soraya having been dissolved, he married Farah Diba, the daughter of Sohrab Diba, an Iranian army captain. A crown prince, named Reza after his grandfather, was born in Teheran on Oct. 31, 1960. *See* also PERSIAN HISTORY.

*See* Mohammed Reza Shah Pahlavi, *Mission for My Country* (1961). (L. Lo.)

**MOHAMMED SHAH** (1702–1748), Mogul emperor of India from 1719 to 1748, the son of Jahan Shah, fourth son of Bahadur Shah I, was born at Ghazni on Aug. 7, 1702. He was made emperor in 1719 by the powerful Sayyid brothers 'Abdullah and Husain 'Ali who had killed the emperor Farrukhsiyar. In 1720 a successful assassination plot against Husain 'Ali by Turani and Irani nobles and the defeat of 'Abdullah at the battle of Hasanpur freed Mohammed Shah from Sayyid tutelage. Nevertheless, he failed to obtain loyal and disinterested service after Nizam ul-Mulk Asaf Jah, appointed *wazir*, had left court in disgust in 1724. While Mohammed Shah went through the outward motions of kingship, the provinces steadily slipped out of imperial control: Sa'adat Khan made himself practically independent in Oudh, the Afghan Rohillas made themselves masters of Rohilkhand; Bengal merely remitted an annual tribute to Delhi, the Marathas under the *peshwa* Baji Rao made themselves lords of Gujarat, Malwa and Bundelkhand, and, in 1737, raided the suburbs of Delhi. Taking advantage of Mogul neglect of the northwest frontier areas, in 1739 Nadir Shah of Persia invaded India, routed the Moguls at Karnal, occupied Delhi and massacred the inhabitants. He returned laden with the Peacock throne and vast booty. The only event to cheer the last years of Mohammed Shah's reign was the defeat of the Afghan, Ahmad Shah Durrani, at Sirhind in March 1748. Mohammed Shah died in Delhi on April 16, 1748.

**MOHAMMED TUGHLUQ** (c. 1290–1351), sultan of Delhi from 1325 to 1351, was born c. 1290, the son of Ghiyath ud-Din Tughluq. Attaining prominence as superintendent of the royal stables under Sultan Qutb ud-Din Mubarak Shah Khalji (1316–20), Mohammed Tughluq was a prime mover in Ghiyath ud-Din's rising (1320) against Khusrau Khan Barwari, Qutb ud-Din's murderer. During his father's reign Mohammed Tughluq headed Delhi forces against Warangal in the Deccan.

Mohammed Tughluq's reign is a watershed in the history of the Delhi sultanate. In 1325 Delhi exercised a hegemony, however slight, over the greater part of the subcontinent; in 1351 it had lost all authority south of the Narmada, after nearly two decades of sporadic revolt against the sultan's rule. Contemporary writers explained Mohammed Tughluq's failures in the light of their own religious beliefs (the sultan appears to have offended important religious personages) or of their own political interests, but modern studies refuse to accept their rhetoric at its face value. Probably the sultan's greatest mistake was to make Daulatabad (*q.v.*) a second capital (1327) and to encourage a Muslim elite to settle in the Deccan with the consequence that local resources soon matched local temptations to throw off the control of distant Delhi. Ma'bar (Madura) was lost to rebels in 1334–35, Gulbarga in 1339, Warangal in 1345–46 and Daulatabad in 1347. In northern India the sultan's resources had suffered from a famine in the doab in 1335 and from a disastrous loss of troops in an expedition in the Kumaon-Gahrwal region (c. 1338). Mohammed died on March 20, 1351, while hunting rebels in Sind.

**MOHAVE** (MOJAVE), a Yuman (*q.v.*) tribe on the lower Colorado river near Needles, Calif. National unity prevailed among the small clusters of dwellings scattered along the periodically inundated bottom lands where crops were grown. Half the vegetal food was derived from mesquite beans and other wild plants. Fishing was considerable, hunting minor. Houses were low, gable-roofed, rectangular structures covered with brush and sand. Men commonly wore only a breechclout, women a full petticoat—both garments being made of woven willow bark. Clay vessels of fair quality were prevalent, basketry was minimal. The Mohave were exceptional in this region as travelers.

Warfare was frequent, undertaken with enthusiasm and often sanguinary. Combat was formalized, the massed company being led by champions. A cylindrical club wielded with an upward smashing blow was the favoured weapon. Their patrilineal exogamous clans were not localized and served largely to provide a bond of fellowship. A unique feature was the use of the meaningless clan name for women alone, who might also be particularized by nicknames. These clan names had totemic reference to animals and plants (*see* TOTEMISM).

Great significance was attached to stylized dreams, which were considered the source of all special powers. In dreams a man projected himself back to the world's beginning, experienced all happenings of the myths and was endowed with ability to cure, hunt, fight, etc. Public ceremonial took the form of singing a cycle of dreamed songs which recited a myth, ordinarily the narrative of a journey. Some cycles consisted of hundreds of songs.

By the 1960s the 18th-century population of about 3,000 had decreased two-thirds.

*See* A. L. Kroeber, *Handbook of the Indians of California* (1925); G. Devereux, "Dream Learning and Individual Ritual Differences in Mohave Shamanism," *Amer. Anthrop.*, vol. 59 (1957); *Mohave Ethnopsychiatry and Suicide* (1961). (L. Sr.)

**MOHAVE DESERT:** *see* MOJAVE DESERT.

**MOHAWK,** the easternmost tribe of the Iroquois confederacy, occupied three villages west of Schenectady, N.Y., beyond Schoharie creek on the south side of the valley of their name. The location and removal of these settlements in historic times links them with Laurentian peoples whom Jacques Cartier encountered between Quebec and Montreal in the 16th century. Their place names—Ticonderoga, Saratoga, Canajoharie, Oneonta—dot the waterways of their tribal territory from Canada to Pennsylvania. On the west were the related Oneida (*q.v.*).

The deep-seated fear and hatred of the Iroquois among descendants of neighbouring Algonkian tribes stems from wars of displacement going back to protohistoric times. The general trend of Mohawk "castles," so called for fortified hilltops situated back from the river, to open townsites on the river plain reflects an enhanced military position at the expense of the Mahican. The trade at Albany in axes, guns and kettles implemented a superior native organization. Traditionally, their leader Hiawatha was the first to accept the principles preached by the prophet of peace Dekanawida, who founded the Iroquois league. The Mohawk had nine representatives in the league, three from each of their village bands of the Turtle, Wolf and Bear, inhabiting 180 houses and comprising over 800 families, or approximately 2,500 people.

After contact with Europeans, their population decreased rapidly. Substantial losses resulted from defections to the Christian settlements on the St. Lawrence river, principally at Caughnawaga; these converts (the "praying Indians of Quebec") espoused the French cause, raided Deerfield for captives and guided expeditions against their erstwhile brothers of the league. The resident Mohawks, "fastening a chain" and "planting a tree of peace" at Albany, tortured the Jesuits, accepted Dutch Reformed ministers and sent three of their young men to London with Peter Schuyler to the court of Queen Anne, requesting military assistance and Anglican missionaries. Their affairs during the mid-18th century were guided by Sir William Johnson (*q.v.*); during the American Revolution they remained loyal to their pro-British leader Joseph Brant (*q.v.*) and followed him to Canada, where they have descendants at the Bay of Quinte and Six Nations reserve at Brantford, Ont. Their total number in the 1960s was about 5,000. A few are successful farmers, but the Laurentian Mohawks are workers in structural steel, having a passion for dangerous occupations. *See* also IROQUOIS.

*See* J. Mitchell, *Mohawks in High Steel* (1956). (W. N. F.)

**MOHINDERGARH,** a town and district in Punjab, India. The town, headquarters of the district, lies 64 mi. S.W. of Delhi on the Delhi-Bikaner railway. Pop. (1961) 9,071. It was founded by Mahdud Khan during the reign of the Mogul emperor Babur. A fort built by the Marathas in the 17th century was renamed in 1861 by Maharaja Narinder Singh after his son, Mohinder Singh. The town is known for embroidered footwear.

MOHINDERGARH DISTRICT (area, 1,313 sq.mi.; 1961 pop. 547,

850), a semiarid tract with stony and sandy ridges on the south, was constituted from exclaves of the former princely states of Jind, Patiala and Nabha. A government college at Narnaul (23,950) is affiliated to Punjab university. There is a cement factory at Dadri (13,839). The Sirsa branch of the Western Jumna (Yamuna) canal provides irrigation. Wheat, gram and millets are the main crops. (S. S. Bh.)

**MOHL, HUGO VON** (1805–1872), German botanist, famous for his recognition of the true nature of cells, was born at Stuttgart on April 8, 1805, and took his degree in medicine at Tübingen in 1828. He then studied for several years at Munich. In 1835 he became professor of botany at Tübingen, retaining that post until his death there on April 1, 1872. Mohl was concerned chiefly with the structure of the higher forms, including both gross anatomy and minute histology. He gave currency to the word "protoplasm," first used by J. E. Purkinje; he recognized under the name of "primordial utricle" the protoplasmic lining of the vacuolated cell and first described the behaviour of the protoplasm in cell division; he observed cell division in the alga *Conferva glomerata*.

Mohl also held the view, later generally adopted, of growth of cell wall by apposition. He was the first to explain the true nature of pits, and he showed the cellular origin of vessels and of fibrous cells. His early investigations on the structure of palms, cycads and tree ferns laid the foundation for all later knowledge of this subject; so also did his work on the quillworts, *Isoetes* (1840). Mohl's later anatomical work was chiefly on the stems of dicotyledons and gymnosperms. He was extremely skilful with the microscope and polished and set his own lenses. Mohl's most notable papers were republished in *Vermischte Schriften* (1845); his *Die Vegetabilische Zelle* appeared in 1851 (Eng. trans., 1852).

**MOHL, JULIUS VON** (1800–1876), German orientalist known for his edition of the Persian national epic *Shah-Nama*, was born at Stuttgart on Oct. 25, 1800. Having studied theology at Tübingen, he abandoned the idea of entering the Lutheran ministry and in 1823 went to Paris, at that time, under Silvestre de Sacy, the great European centre of oriental studies. In 1826 he was charged by the French government with the preparation of an edition of the *Shah-Nama* ("Book of Kings"), which became his lifework. The first volume appeared in 1838; the seventh and last was left unfinished at his death, being completed by Barbier de Meynard. In 1844 he was nominated to the academy of inscriptions and in 1847 became professor of Persian at the Collège de France. He served for many years as secretary and then as president of the Société Asiatique. His annual reports on oriental science from 1840 to 1867, collected after his death under the title *Vingt-sept ans d'histoire des études orientales* (1879), are an admirable history of the progress of eastern learning during these years. He died in Paris on Jan. 3, 1876.

His wife, Mary (1793–1883), had passed a great part of her early life in Paris, where she was a close friend of Mme Récamier (*q.v.*). For nearly 40 years her house was one of the most popular intellectual centres in Paris.

**MÖHLER, JOHANN ADAM** (1796–1838), German Roman Catholic church historian, renowned as the "theologian of church unity," was born at Igersheim, Württemberg, on May 6, 1796. Ordained to the priesthood in 1819, he taught church history in the Roman Catholic faculty of the University of Tübingen from 1826 to 1835 and then, until his death, on April 12, 1838, at the University of Munich.

Outstanding among his half-dozen books is *Symbolik* (on the creeds), first published in 1832 (Eng. trans. by J. B. Robertson, 1843). In this work, as in his earlier volume *Die Einheit in der Kirche* ("Unity in the Church," 1825), Möhler argued that man's journey to God could be made only in the church founded by Christ. His longing for church unity induced him to engage in discussion with Protestant scholars of his day so as to find a basis for mutual understanding which, he hoped, would eventually lead to acknowledgment that the church must be undivided. His unflagging efforts on behalf of Christian reunion have made him a theologian of increasing importance and influence in the ecumenical movement of the 20th century.

*See* Gustav Voss, "Johann Adam Möhler and the Development of Dogma," *Theological Studies*, vol. 4, pp. 420–444 (1943); Serge Bolshakoff, *The Doctrine of the Unity of the Church in the Works of Khomyakov and Moehler* (1946). (C. V.)

**MOHOLY-NAGY, LASZLO** (Ladislaus) (1895–1946), Hungarian painter, photographer and art teacher, was born at Bacsbarsod, Hung., July 20, 1895. He studied law in Budapest, joined the poetry circle of Endre Ady and published woodcuts of Cubist influence in the avant-garde journal *Ma*. He went to Berlin in 1921 to realize his vision of a nonrepresentational art consisting of pure visual fundamentals: colour, texture, light and equilibrium of forms. In 1923 he headed the metal workshop of the Bauhaus school and edited the *Bauhausbook* series. During his Bauhaus years (1923–29) he evolved the two contributions for which he is known.

As painter and photographer he worked predominantly with light. His "photograms" were composed directly on the film and his "light modulators" (oil paintings on transparent or polished surfaces) included mobile light effects. As an educator, Moholy-Nagy evolved a widely accepted curriculum developing natural visual gifts instead of specialized skills in the student. His dictum was: "Everybody is talented." Fine arts training was abolished in favour of "designing the whole man." In 1937 he organized in Chicago, Ill., the New Bauhaus (later the Institute of Design), the first American school based on the Bauhaus program. He died Nov. 24, 1946, in Chicago.

*See* also Painting: *Bauhaus Group*.

Bibliography.—L. Moholy-Nagy, *The New Vision*, 4th ed. (1947) and *Vision in Motion* (1947); D. M. P. A. S. Moholy-Nagy, *Moholy-Nagy, Experiment in Totality* (1950). (S. D. M.-N.)

**MOHR, CHRISTIAN OTTO** (1835–1918), German engineer whose most important work was the development of methods of calculating stresses and deformations in frameworks, girders and arches. He was born at Wesselburen on Oct. 8, 1835, and entered Hanover polytechnic at the age of 16. After completing his schooling he worked as a structural engineer on railways in Hanover and later in Oldenburg. In 1867 Mohr became professor of engineering mechanics at the Stuttgart Polytechnic, where he achieved a high reputation as a lecturer. In 1873 he moved to the Dresden polytechnic, where he taught until 1900. After his retirement from teaching he continued his scientific work at his home near Dresden until his death on Oct. 2, 1918.

Mohr devised many graphical methods of solving engineering problems. One of these, the Mohr stress circle, which represents the state of stress at a point in a material, is well known to engineering students. His theory of failure of materials has received much attention but is of limited application. Altogether, he published about 40 papers as well as his collected works. (B. S. O.)

**MOHR, KARL FRIEDRICH** (1806–1879), German chemist, designer of laboratory apparatus and one of the originators of the doctrine of the conservation of energy, was born at Coblenz on Nov. 4, 1806, the son of a chemist. He studied under L. Gmelin and, after five years at Heidelberg, Berlin and Bonn, returned to Coblenz to assist his father. He gave up business in 1857, and devoted himself to research work until 1863 when he returned to the university at Bonn, where he became a professor in 1867. He died there on Sept. 28, 1879.

Mohr was the leading scientific pharmacist of his time in Germany; he was the author of many improvements in analytical processes. He invented the pinchcock, the cork borer, Mohr's balance for the determination of specific gravities and other pieces of apparatus. His methods of volumetric analysis were expounded in his *Lehrbuch der chemischanalytischen Titrirmethode* (1855). His *Geschichte der Erde* (1866) also obtained a wide circulation. In a paper "Über die Natur der Wärme," in the *Zeitschrift für Physik* (1837), he gave one of the earliest general statements of the doctrine of the conservation of energy.

**MOHS' SCALE.** One of several ways of determining the hardness (designated H) of a mineral is by testing its resistance to scratching or abrasion. This test is performed by observing if the smooth surface of a mineral of unknown hardness is scratched by a sharp edge or point of a series of minerals or other substance

whose hardnesses are known. Rapid mineral identification is greatly facilitated whenever the approximate hardness is easily determinable.

A series of ten minerals (all common except the last, diamond) has been devised, as an arbitrary scale of reference, against whose hardnesses the relative hardness of any other species may be checked. This scale of species, arranged in order of increasing relative hardness, is:

| | |
|---|---|
| 1. Talc | 6. Feldspar |
| 2. Gypsum | 7. Quartz |
| 3. Calcite | 8. Topaz |
| 4. Fluorite | 9. Corundum |
| 5. Apatite | 10. Diamond |

Thus if a mineral is scratched by feldspar but not by apatite, its H = 5.5. It is known as the Mohs' scale of hardness after its originator Friedrich Mohs (1773–1839), German mineralogist, who first revealed it in 1812.

In the determination procedure it is necessary to observe whether the known species is harder and is actually producing a groove, or whether it is softer and is itself being abraded by the unknown to leave a removable mark. If the unknown species is fine grained, friable or pulverulent, the scratch test may only loosen grains from the aggregate without testing the individual mineral surfaces; thus certain textures or aggregate forms may hinder or prevent a true hardness determination.

As supplements to the mineral scale there usually are added: fingernail, 2+; copper penny, about 3; pocketknife blade, 5+; ordinary window glass, 5.5; and steel file, 6.5. (E. W. Hu.)

**MOIETY,** as commonly used in social anthropology, a type of dual division of a society based on descent groups. The clans of a tribe may be paired into two opposing moieties for such purposes as the maintenance of marriage rules, organization of war parties and participation in games and ceremonies. *See* DUAL ORGANIZATION.

**MOIRÉ,** a textile fabric with a distinctive watered pattern visible because of the varying angles at which rays of light are reflected from the design areas that have been pressured into the fabric. Although a ribbed weave is more conducive to a moiré effect, similar effects can be obtained with other fabrics of similar texture, more popularly those produced from silk, rayon, acetate and mercerized cotton.

Various finishing methods may be used. In the earlier method the material was first dampened and then folded with the face side inward and with the two selvages running together side by side. The cloth was then put under considerable pressure for several hours. This gave a lasting watered effect but the folds produce objectionable creases and the process is no longer used in the United States. In the more modern method the design is pressed into the fabric by means of engraved rollers. Effects similar to moiré can be obtained by overprinting in a shade of the same colour and also by weaving a pattern of a watered design.

Watered fabrics date from the middle ages in Europe and from a much earlier period in the orient. One of the popular early watered fabrics was made of mohair. The French term for a watered mohair became *la moiré ondée;* the word for watered, *ondée,* was gradually omitted and the term moiré used to mean any type of watered fabric. (G. R. Co.)

**MOISSAN, HENRI** (1852–1907), French chemist, winner of the 1906 Nobel prize in chemistry for his isolation of the element fluorine and development of the Moissan electric furnace, was born at Paris on Sept. 28, 1852. He was educated in Edmond Frémy's laboratory at the Musée d'Histoire Naturelle and attended lectures by H. E. Sainte-Claire Deville and Henri Debray. He received his doctoral degree in 1885 with a thesis on the cyanogen series. In 1879 he was appointed to a junior post in the Agronomic institute, Paris, and was subsequently professor of toxicology (1886) and of inorganic chemistry (1889) at the school of pharmacy and of inorganic chemistry (1900) at the Sorbonne. He was awarded the Lacase prize in 1887. He died in Paris on Feb. 20, 1907. Moissan often said, "Fluorine has shortened my life ten years."

Moissan's first research was on a biological problem and dealt with the interchange of oxygen and carbon dioxide in leaves, but he soon went over to inorganic chemistry. His early work in this field was on the oxides of the iron group metals, and of chromium; he also made a careful study of the chromous salts. In 1884 he turned to the study of fluorine and prepared several new compounds, including phosphorus and organic derivatives. In 1885 he found that potassium fluoride could be dissolved in certain proportions in liquid hydrofluoric acid to give a solution which conducted electrolytically and which remained liquid at low temperatures. A year later by electrolyzing this solution in a platinum tube using platinum-iridium electrodes he obtained for the first time the highly active fluorine gas. He made a full study of the properties of the gas and of its combinations with other elements.

In 1892 Moissan developed the electric arc furnace as a means of obtaining high temperatures for experimental work. By its aid he prepared many new compounds, especially carbides, silicides and borides, and melted and volatilized substances which had previously been regarded as infusible. His claim to have prepared tiny artificial diamonds (*see* GEM, *Synthetic Gems*) by cooling rapidly a solution of carbon in molten iron was not confirmed. He discovered the abrasive carborundum (silicon carbide) but this method was not suitable for commercial production. He studied the chemistry of the carbides and the action of water on them, and was led by the results to suggest that petroleum formation may be caused by a similar process occurring in the earth. Moissan also prepared the hydrides of calcium, sodium and potassium, finding them to be nonconductors of electricity.

He was one of the best scientific lecturers in Paris. He was a skilled experimenter and insisted that his laboratory be immaculate. Even a few drops of water on the floor brought a rebuke.

Moissan's published works include *Le Four électrique* (1897) and *Le Fluor et ses composés* (1900), besides numerous papers. A *Traité de chimie minérale* (five volumes) was published under his direction in 1904–06.

**MOISSI, ALEXANDER** (1879–1935), Austrian actor, was born on April 2, 1879, at Trieste on the Adriatic sea. His father was Albanian, his mother Italian. While taking voice lessons in Vienna, Moissi had the opportunity (frequently as a supernumerary) to study the acting technique of Josef Kainz, the star of the Imperial Burgtheater, whom he was to emulate first in Prague, then at Max Reinhardt's Deutsches Theater and Kammerspiele in Berlin. During World War I, Moissi was interned in Switzerland. After his release in 1917 he became associated once again with Reinhardt's enterprises in Berlin and Vienna.

In 1920, when the Salzburg festival was initiated, he was the first Jedermann in Hugo von Hofmannsthal's version of the old morality play. But his greatest parts remained Fedja in Leo Tolstoi's *The Living Corpse,* Oswald in Henrik Ibsen's *Ghosts,* Hamlet, Oedipus and Montezuma in Gerhart Hauptmann's *Der weisse Heiland*—roles in which the neuroses of a melancholiac could be expressed in terms of vocal lyricism.

Moissi died in Vienna on March 22, 1935. (A. M. N.)

**MOJAVE DESERT,** an arid region of eastern California, United States, lying north of the San Gabriel-San Bernardino mountains and extending from the southern Sierra Nevadas to the Colorado river valley, south of latitude 36°. Southeastward it merges into the Yuma desert (*q.v.*). The area has typical mountain-and-basin topography; steep rugged mountains rise abruptly above broad basins floored smoothly with sand and gravel and draining to central salt flats.

Summer days are hot (maximums over 100° F.); winters have warm days (50°–60° F.) and cold nights (17°–30° F.). Frosts are common in winter and snow occasionally falls. Annual rainfall averages less than five inches.

In the basins, vegetation consists of widely-spaced low shrubs, especially creosote bush and burroweed. Cacti occur sparingly on south-facing rocky slopes. Higher areas have thicker brush and

some stands of weird Joshua trees (*Yucca brevifolia*). The highest mountain ranges have open woodlands of piñon and juniper.

The northern portion is grazed by cattle. Various chemicals are extracted from the salt flats and there is some mining. The southwestern part, adjacent to Los Angeles, is undergoing rapid urban and recreational development. (R. F. Lx.)

**MOJI:** *see* Kita-Kyushu.

**MOKP'O,** a port and city at the southwestern tip of Korea, became a thriving commercial seaport after its opening to foreign trade in 1897. The deep harbour is well sheltered by peninsulas and islands. Rail lines connect Mokp'o to the inland areas and make the port a major commercial centre of southwest Korea.

The industries of the city are rice milling, cotton ginning, brewing, fish processing and vegetable oil milling. Pop. (1960) 129,667. (S. McC.)

**MOLASSES** is the syrup remaining from the crystallization of sugar from cane or beet juice (*see* Sugar). It is separated from sugar by centrifuging and contains impurities present in the cane or beets. Cane molasses contains about 14% invert sugar as compared with about 1% in beet molasses. Final or blackstrap molasses has had all of the sugar removed from it that can practically be separated by ordinary crystallization. Edible grades of molasses, called treacle in Great Britain, are higher in sugar and are usually partially decolorized; their flavour is sweeter and milder.

Until 1948 the principal use for molasses was fermentation to produce industrial ethyl alcohol and rum. Production of alcohol from ethylene decreased the market for fermentation alcohol and caused a lowering in the price of molasses, which made it more attractive as a feed for farm animals, thereafter its principal market. The addition of urea and other nonprotein nitrogen to molasses enables the microorganisms in the rumens of cattle and other ruminants to synthesize their own protein from these sources. The animals digest the bacteria and protozoa. (H. B. Hs.)

**MOLAY, JACQUES DE** (*c.* 1243–1314), last grand master of the Knights Templars, who notably failed in leadership when the order was attacked, was born at Molay (Jura). He entered the order in 1265, fought in Syria and after 1291 was at Cyprus. He was elected grand master in about 1298. Summoned to France (1306 or 1307) by Pope Clement V to discuss a new crusade and the amalgamation of the Templars with the Hospitallers, Molay opposed any union and asked the pope to investigate accusations made against his order. On Oct. 13, 1307, all the Templars in France, including Molay, were arrested and interrogated by command of Philip IV. On Oct. 24, 1307, Molay agreed that on admission to the order he had denied Christ, but he rejected a charge of sodomy. He wrote to Templars throughout France, enjoining confession, but when the pope sent his own delegates to conduct the inquiries, Molay and many of his subjects retracted their statements, saying they had been exacted by torture. In Nov. 1309 and in March 1310 Molay appealed for a personal judgment by the pope. But Clement formally suppressed the order in Nov. 1312, and on March 18 or 19, 1314, a commission of three cardinals condemned Molay and other dignitaries of the order to perpetual imprisonment. On hearing this sentence they again retracted their statements and were burned as relapsed heretics by Philip IV's officers the same afternoon. *See* also Templars.

**MOLD** (Yr Wyddgrug), a market town, urban district and the county town of Flintshire, Wales, is the natural centre of the fertile Alun (Alyn) valley and lies 11 mi. W. of Chester by road. Pop. (1961) 6,857. The town's wide High street, crowded with open stalls on market days, rises to the noble Perpendicular church of St. Mary. Above this is Bailey Hill, an impressive motte and double bailey castle, in shape resembling a figure 8. It was probably built by Robert de Montault, shortly after the conquest of the Alun valley by the Normans in the reign of William II (Rufus). Henry III rebuilt the castle, but hardly any trace of stonework survives. In the 200 years of war between the Welsh and Normans the castle changed ownership many times and the small town which grew up nearby was frequently burned and pillaged.

The famous Mold corslet, a gold ceremonial cape, was discovered in a large Late Bronze Age barrow at Bryn yr Ellyllion (hill of goblins) in 1833 and is now in the British museum, London. It is believed that the site was on or near an important gold route from Ireland to Wessex and the continent. Mold was the centre of a lead- and coal-mining district, the last colliery having been closed in the mid-20th century. Daniel Owen (1836–95), the 19th-century Welsh novelist, was born and worked as a tailor in Mold; his statue ornaments the County Hall field. The town's industries include the making of agricultural machinery. Quarrying and agriculture are the main sources of employment in the district. Mold is also a tourist centre.

Maes Garmon, 1 mi. W. of Mold, has an obelisk raised in the 18th century, claiming that the site, Germanus' field, is the battlefield where the Britons under St. Germanus won the Alleluia victory over the Saxons and Picts, a story found in Bede. (M. B.-Ev.)

**MOLDAVIA** (Rum. Moldova; Turkish Bogdan), one of the two Danubian principalities from which Rumania was constituted in the 19th century. It emerged as an independent state in the middle of the 14th century, under its voivode or prince Bogdan. At its greatest extent, when it included Bessarabia, it was bounded on the north and the northeast by the Dniester river; on the south by the Black sea, Dobruja and Walachia; and on the west by Transylvania. Having long been subjected to pressures from Poland and from Hungary, Moldavia finally became a vassal of Turkey in the 16th century, by which time the Bessarabian coastal area had already been detached from it. The Russo-Turkish treaty of Kuchuk Kainarji (1774) improved the principality's status, but Bukovina, the northwesternmost area, was annexed by Austria. All Bessarabia was taken by Russia under the treaty of Bucharest (1812), but the southernmost part was restored to Moldavia by the treaty of Paris (1856). The union of Moldavia with Walachia (Nov. 9, 1859) paved the way for an independent Rumania. *See* Rumania: *History;* Moldavian Soviet Socialist Republic.

**MOLDAVIAN SOVIET SOCIALIST REPUBLIC** (Moldavskaya S.S.R. or Moldavia) is the smallest of the 15 constituent republics of the U.S.S.R., covering 13,012 sq mi. It lies in the extreme southwest, between Rumania on its southwest and the Ukrainian S.S.R., which surrounds it to north, northeast and southeast.

The republic occupies the basins of the middle Dniester and Prut. The Dniester, which forms the boundary with the Ukraine in the north, flows through northeastern Moldavia, while the Prut forms the whole length of frontier with Rumania. Between the relatively narrow flood plains along the rivers are the hills of the Bessarabian upland (Bessarabskaya Vozvyshennost), which are greatly cut up by the deep, narrow valleys of the tributaries of the Dniester and Prut. The upland can be divided into subregions: the Khotin upland of the northwest, the Northern Hilly plain around Beltsy, the Dniester uplands running parallel to the river, the Kodry uplands of the centre, the Southern Hilly plain and the Baimakliya heights in the extreme south. The highest point of Moldavia, 1,409 ft., is located in the Kodry.

The climate of Moldavia is one of the mildest in the U.S.S.R., with winter conditions much modified by the passage of depressions across the Black sea. In January average temperatures range from −3° C. (27° F.) in the south to −5° (23°) in the north. Thaws are frequent throughout the winter. July temperatures also vary from north to south, between 20° (68°) and 23° (73°). Rainfall is 22 in. a year in the north to 12–16 in. in the south, with a spring-summer maximum.

The northern part of Moldavia is part of the forest-steppe zone, the south belongs to the steppe. Soils, although displaying considerable local variation, are mostly related to the chernozem group. Very little of the natural feather grass steppe vegetation has survived, and the forest areas too have been ruthlessly cleared for agriculture, until only 6% of the area of the republic remains forest-covered. The surviving forests are mainly deciduous, with many west European species.

**History.**—Moldavia, or Bessarabia (the name often given to the Dniester-Prut interfluve), has a long and stormy history. Part of Scythia (*q.v.*) in the first millennium B.C., it later came marginally under the control of the Roman empire as part of Dacia (*q.v.*). Lying on the great routeway into Europe it was invaded by successive waves of barbarians, and the area knew many masters. Gradually, under varying influences, the Vlach or Walachian nationality developed. Part of the area came under Kievan Russia in the 10–12th centuries A.D., and passed later to the Galician princes. From 1240 to the 14th century Moldavia was vassal to the Tatars but, after a brief period under Hungary, in 1359 an independent princedom was achieved under the voivode Bogdan. His successor, Stephen the Great (who reigned as prince from 1457 to 1504), successfully resisted the growing power of Turkey, but on his death Moldavia fell under the Turkish yoke. For the next 300 years it was a strongly fortified border region of Turkey and was fought over in many Russo-Turkish campaigns. After the 1792 treaty of Jassy small areas in present-day eastern Moldavia were ceded to Russia, but by the 1812 treaty of Bucharest all Moldavia as far as the Prut passed to Russia. Thereafter considerable Russian colonization took place and in 40 years the population was quadrupled.

In 1918, after the Revolution, Moldavia voted for union with Rumania. The boundary lay along the Dniester, on the eastern bank of which the Moldavian Autonomous S.S.R. was formed in 1924. In 1940 Rumania ceded Bessarabia to the U.S.S.R. and the area was added to the Autonomous S.S.R. to form the Moldavian S.S.R. A year later the German onslaught overran Moldavia, and occupation by Rumanian troops lasted until the spring of 1944. (*See* also BESSARABIA; MOLDAVIA.)

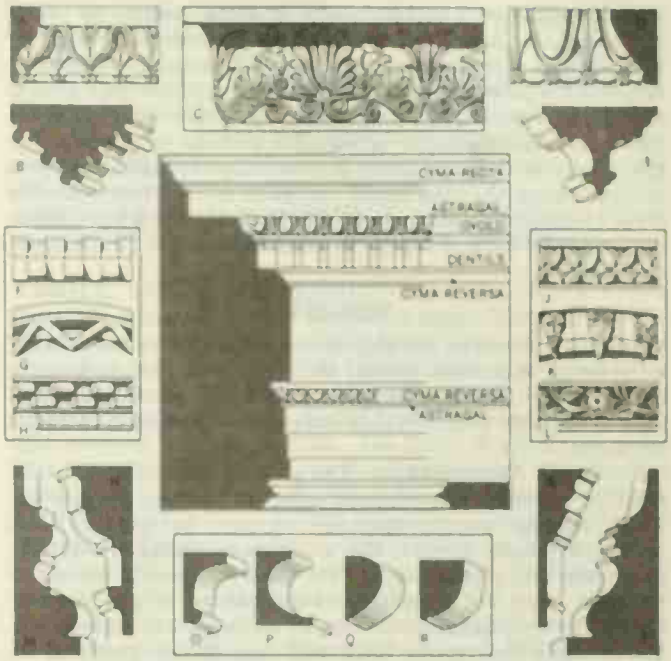
**Population and Administration.**—The 1959 census enumerated 2,884,477 people in Moldavia. Of these 1,887,000 (65.4%) were Moldavians, 421,000 (14.6%) were Ukrainians and 293,000 (10.2%) Russians. Other nationality groups were the Turkic-speaking Gagauzy 96,000 (3.3%), Jews 95,000 (3.3%) and Bulgars 62,000 (2.1%), with a few Greeks and gypsies. The Moldavians are Walachian in origin, related to the Rumanians. Their language shows strong Latin and Slavic influences. The urban population of 642,244 represents only 22.3% of the total. There are 17 towns and 21 urban districts, but the only one of size is the capital, Kishinev (*q.v.*), with 216,005 inhabitants. Beltsy has 67,114 people, but of the other important towns, Tiraspol, Bendery, Rybnitsa and Soroki, none reaches 50,000 inhabitants. The suitability for agriculture of the good soils and mild climate has given rise to a dense rural population. The overall density of 222 persons per square mile is the highest of all the union republics. Living standards and the provision of social services are steadily improving, although in these respects Moldavia tends to be one of the more backward republics.

The supreme soviet, elected in 1959, consists of 281 deputies including 104 women. The Moldavian Academy of Sciences was established in 1961 at Kishinev, and there are more than 40 research institutes and 800 medical centres in the republic.

**Economy.**—Moldavia is often regarded as the garden of the U.S.S.R. Vineyards and orchards are extensive, especially along the Dniester and in the Kodry uplands. Moldavian wines are highly rated in the Soviet Union. Fruits grown include apples, pears, plums, apricots, peaches, cherries, quinces, strawberries and walnuts. Grains, especially wheat and maize (corn), are the main field crops. Sunflowers, soybeans, sugar beet and tobacco are important industrial crops. Melons and potatoes are widely grown. Livestock husbandry, chiefly sheep and goats, is not well developed. Beekeeping is widespread and in the southeast there are mulberry plantations for silkworms. Industry is chiefly concerned with processing agricultural products (wine making, distilling, brewing, jam making, canning, flour milling, etc.), and is carried on widely in small-scale undertakings. Timber is cut in the Kodry, in the centre of the republic, for crate making. Engineering is important at Kishinev and Beltsy. (R. A. F.)

**MOLDAVITE:** *see* TEKTITE.

**MOLDING,** in architecture and the decorative arts, is a transitional or terminal element usually appearing horizontally in a cornice, architrave or capital, or curved in an arch. A molding is a modeled surface, most frequently a band and approximately continuous, with a constant profile or one with rhythmically repeated elements. Moldings doubtlessly originated in prehistoric building, where they served specific structural functions. As monumental architecture developed, moldings were gradually translated from wood or other ephemeral materials into more permanent ones, most often stone. In this gradual transition moldings were retained as a matter of conservatism or taste; in stone they were elaborated and refined, contributing order and richness to a decorative system.



SOME TYPES OF MOLDING

(A) Greek cyma reversa with the water leaf; (C) Greek cyma recta with anthemions; (D) Greek ovolo with egg and dart; (I) classic entablature; (M, N) Roman base and capital; (S, T) Greek capital and base; (F) Byzantine dentil; (G, H, J, K) Romanesque; (B, L) English Gothic; (E) Elizabethan; (O) cavetto and torus; (P) scotia; (Q) torus; (R) ovolo

Although their original structural function was satisfied by other means, moldings were used in a manner that implied a structural logic. From this usage, best characterized in the orders of architecture of ancient Greece (*see* ORDER), it was possible later to develop theories for the correct form and employment of moldings, according to which several basic shapes were standardized in the vocabulary of architectural design.

## TYPES OF MOLDING

**Flat or Angular.**—(1) The facia, face or band is a continuous member with a flat surface, parallel to the surface it ornaments and either projecting from or slightly receding into it. (2) Fillet, listel or regula are terms for a relatively narrow band, usually projecting, commonly used to separate curved moldings or to finish them at top or bottom. (3) Bevel or chamfer molding is an inclined band, facia or fillet. (4) A splay is a large bevel.

**Single Curved.**—(1) The cavetto is a concave molding with a profile approximately a quarter-circle, quarter-ellipse or similar curve. (2) Scotia molding is similar to the cavetto, but has a deeper concavity partially receding beyond the face of the general surface which it ornaments. (3) A flute is a small groove of semicircular, segmental or similar section. (4) Ovolo, a convex molding, has a profile approximating a quarter-circle or quarter-ellipse. (5) Torus, a convex molding, approximates a semicircle or semiellipse. (6) Roll or bowtell molding is convex, approximating three-quarters of a circle. (7) An astragal is a small torus, often with fillet attached below. (8) Apophyge molding is a small exaggerated cavetto.

**Compound.**—(1) The cyma recta, a projecting molding, con-

sists essentially of a cavetto above an ovolo, forming in profile one continuous double curve, often used as a crowning member, in which case it is sometimes known as a cymatium. When used as a base the convex portion is uppermost. (2) The cyma reversa or ogee, a projecting molding essentially a reversed cyma recta with ovolo above cavetto, is used for a crown or a base. (3) Bird's beak or thumb molding is essentially similar to the cyma reversa, except that the upper convexity is separated from the lower concavity by a sharp edge. (4) Keel molding is a projection consisting of a roll molding with a small fillet attached at its outermost surface.

## HISTORY

The basic forms of molding developed largely in the classical architecture of ancient Greece, although there were some similarities in pre-Greek architecture. They persisted with modifications in the main stream of architectural development in the western world.

**Pre-Greek Architecture.**—The most conspicuous early use of moldings in architecture occurred in Egypt, probably by 3000 B.C. There, building having progressed from reeds and mud to stone, walls were usually crowned with a cornice consisting of a cavetto underlined with a small torus. The torus was usually painted to represent reeds tied together, and the cavetto with a series of vertical forms suggesting the tops of reeds used as walling. In Mesopotamia the typical brick wall construction produced an architecture in which moldings were practically absent.

Archaeological evidence has indicated that moldings appeared on Hittite columns and the arched portals of the Assyrians. In ancient Persia the shafts of columns were ornamented with flutes and the capitals with moldings of floral inspiration. In Aegean architecture the ovolo was used in the capitals of columns at Cnossus (*c.* 1500 B.C.) and Mycenae (*c.* 1200 B.C.) in much the same way as the echinus of the later Greek Doric column.

**Greek Architecture.**—The Doric was the first and simplest order of architecture developed by the Greeks; its essential elements having taken permanent form by the end of the 7th century B.C. In the Doric order, moldings still retained much of their original structural appearance, being restricted largely to a variety of facias and a cymatium in the cornice. Most attention was given to refining the bulging elliptical profile of the echinus (an ovolo) of the capital of the column, which by the 5th century B.C. had become almost a straight line.

The Ionic order was also fully developed, through the Ionians of Asia Minor, by the 5th century. There the angularity of the Doric yielded to the plastic surface; curved moldings predominated, adding sculptural richness to the total effect. And the curved moldings themselves were enhanced, especially in the Hellenistic period, by carving inspired from natural forms. Although the basic profiles remained, the moldings were given additional names descriptive of their decoration. Thus the simple tubular astragal became the bead and reel, consisting of elliptical beads separated by disklike reels. The ovolo became the egg and dart, consisting of ovoid solids framed with sharp ridges of similar curvature, separated from each other by vertical dart shapes. The cyma recta was adorned with the anthemion (a stylized honeysuckle or palmette) or the acanthus leaf. The cyma reversa was enriched by a repetition of leaf forms, tonguelike in appearance and separated by slender stems, usually called the leaf and tongue or tongue and dart molding. The torus was sometimes fluted, horizontally, or carved in guilloche, an intricate pattern of interlacing bands winding around circular buttons. The cavetto and scotia usually remained undecorated.

The moldings of the Corinthian order were similar to the Ionic; and in all three orders moldings were often painted. Furthermore, Greek molding profiles were characterized by a constantly changing radius of curvature and were usually quirked, having the convex (or concave) moldings brought sharply in (or out) at the top to emphasize shadow. Subtlety of profile and delicacy of carved detail were characteristic of Greek molding.

**Roman Architecture.**—Moldings in Roman architecture, based on modifications of the three Greek orders plus the Tuscan, were more vigorous and robust in appearance. Although the basic profiles and decorative systems were retained, the moldings suggested the work of the engineer more than the sculptor. The curves were often determined mechanically, and the standardized details revealed some quality of mass production. Nevertheless, the tendency was toward greater richness, and among new surface decorations were stylized fish scale or imbrications, spiral rope moldings, rows of flat vertical leaves and others.

**Early Christian and Byzantine Architecture.**—Classical forms in architecture persisted for several hundred years after the decay of Rome in the 4th century. In early Christian churches secondhand Roman moldings and other details were often used in combinations violating the strict canons of classical composition. Similar naïveté or decadence was especially apparent in the Syrian churches of the 5th and 6th centuries, where moldings were usually in the form of a large torus draped like a heavy ribbon, alternately horizontal and vertical, in one sinuous line, without regard for the original logical arrangement.

Likewise in Byzantine architecture, from the 6th century on, moldings were reduced to their simplest elements and used sparingly. The articulation of moldings on wall or entablature was less favoured than broad, smooth surfaces of rich inlaid materials. Moldings were often reduced to two-dimensional patterns; the molded entablature block over the column was simplified to an inverted truncated pyramid (the dosseret), with carving in low relief.

Basic Byzantine forms were perpetuated in the medieval architecture of Greek and Slavic lands. They persisted through the 16th century in Russia, where the principal molding was a large, bold torus ornamented with stylized animal and vegetable figures; the simple curvature of an arch was often interrupted by sharp angles with similar designs. In these derivative styles moldings assumed a purely decorative character.

**Islamic Architecture.**—Roman and Byzantine forms were adopted as the architecture of Islam, which lacked a national building tradition. Thus the variety in Muslim architecture depended on the pre-existing architecture of conquered provinces, and moldings were used according to local traditions. The most conspicuous instance was the revival and perpetuation of Byzantine architecture by the Ottoman Turks, from the 16th century on. In the eastern expansion of Islam, however, Persian influence predominated over Byzantine, and moldings were further reduced in favour of smooth decorated surfaces.

This development culminated in the 17th century in India, in such structures as the Taj Mahal at Agra, where small moldings appeared with considerable delicacy and originality. The Muslim architecture of India was little influenced by the earlier Indian style.

**India and the Far East.**—Although early architectural decoration in India was related in some degree to Greek prototypes, the Buddhist and Hindu artistic traditions were largely an independent development. The decorative system requires a vocabulary of its own, although it can be described approximately in classical terms. The molding forms most frequently used were similar to the facia, bevel, ovolo (inverted) and torus. Usually large in scale and frequently carved with natural leaf forms, they were characteristically composed in layers with sharp shadow lines, producing a stacked-up, sculptured effect. Similar compositions occurred in southeastern Asia.

In China and Japan the prevalent use of wood reduced the role of moldings to the decoration of masonry bases for walls and columns, where a simple torus was often undercut to produce a powerful line of shadow.

**Pre-Columbian Architecture.**—The architecture of America before Spanish conquest in the 16th century also requires descriptive terms of its own. However, the stone moldings most commonly appearing in Mayan, Toltec and Aztec art approximate the basic classical profiles. Base courses and cornices were often large sweeping bevels. Broad facias were used to frame panels of abstract geometrical sculpture or stylized animal forms. Similar decorative bands—sometimes horizontal, sometimes crenelated—provided the major articulation of large wall surfaces. Survivals

of this decorative tradition gave a strong indigenous stamp to later Spanish buildings.

**Romanesque Architecture.**—In western Europe basic Roman forms persisted into the 11th and 12th centuries, the Romanesque period. Through crudity of technique, moldings tended to be robust and simple, consisting chiefly of roll moldings on the edges of arches, and of cavettos and cyma reversas in cornices and in the capitals of columns. However, innovations and variations appeared in the regional schools of Romanesque architecture. In Tuscany and Provence the nearest approximation of antique classical forms obtained. In Lombardy moldings (often brick) were enriched with spirals and other geometrical forms reminiscent of barbarian jewelry.

In the Norman Romanesque of France and England the classical shapes were broken with zigzags and chevrons, or studded with little pyramids and birds' heads. There were such varieties as the billet molding, being a torus broken into small separated sections, and the rope or cable molding, a spirally carved molding that resembles a rope. Many of these details were originally accentuated in brilliant colours.

**Gothic Architecture.**—The old forms were further modified in the Gothic period, extending from the 13th through the 15th centuries. The new structural system based on the ribbed groin vault and pointed arch provided new opportunities for an integral decorative system. Keel moldings on arches and ribs became standard. The cyma, cavetto and torus were used in cornices and capitals, but with increasing exaggeration and originality in form, and often decorated with crockets. In the late, or flamboyant, Gothic of the continent there was the greatest variety of moldings, composed with alternations of sharply projecting members and deep shadows, often interpenetrating in complex tracery patterns, but with a general vertical emphasis.

In the early Gothic of England, especially the Decorated period, forms were more complicated, the moldings consisting of a combination of basic forms worked into one deeply undulating profile; while later, in the Perpendicular period, a general simplicity and flatness was common. Richness was provided by carvings of vine patterns, or repetitions of rosettes (or the Tudor rose), square blocks or heraldic insignia. In the late Gothic period, on the continent as in England, many forms of stone moldings were adapted to timber framing and wood paneling.

**Renaissance and Baroque Architecture.**—Roman classical forms were revived in Italy in the 15th century and soon transmitted to all western Europe. In the early Renaissance there were some compromises with vestiges of medieval forms; in the 16th century the strict rules of classical usage were well understood. However, by the late 16th century, especially in the work of Michelangelo, moldings were treated with a strong sense of sculptural plasticity and freedom in composition, which led to the inventiveness of the baroque. The qualities of the baroque depended on compositions in curving lines and receding surfaces, integrated with sculpture and colour. They attained their greatest richness in the Spanish churrigueresque style, especially in Mexico, and greatest delicacy in the decorative arts of the Louis XV style in France.

Reaction to the exuberance of the baroque came in the 18th century, from the prestige of official art academies, when the return to strict classical forms inevitably led to the imitative neoclassical style.

**The 19th and 20th Centuries.**—The romantically inspired neoclassical style of the 19th century initiated a general eclecticism, in which moldings appeared in classical, medieval, oriental or Renaissance style, or in combinations of them, not only in stone and brick, but in plaster, wood and cast iron.

Out of this stylistic confusion of the Victorian period came the search for new and appropriate forms, notably in the work of Louis Sullivan (U.S.). Moldings were once again inspired directly from nature, especially the nature of the building materials concerned, and used according to structural or functional logic. This provided a new aesthetic for modern architecture, in which classical or other historical moldings have disappeared. Modern moldings, whether in wood, masonry or metal, have generally acquired the simpler forms of functional structural elements and a correspondingly limited use.

In traditional carpentry, however, the basic classic profiles have survived as standard manufactured moldings with a descriptive vernacular nomenclature, including apron, base, beak, bed, bolection, chain, crown, dentil, drop, edge, flush, hip, neck, panel, paternoster, pellet, reeding, roll, scroll, shoe, thumb, tooth, wave and zigzag moldings.

*See* ORNAMENT, ARCHITECTURAL; CAPITAL; DOGTOOTH; JOINERY; *see* also references under "Molding" in the Index.

(E. A. C.)

**MOLÉ, LOUIS MATHIEU,** COMTE (1781–1855), French statesman, a monarchist who held office under Napoleon I, Louis XVIII and Louis Philippe, was born in Paris on Jan. 24, 1781, the son of Edouard François Molé de Champlâtreux, a president in the Paris *parlement*. His father was guillotined in 1794; but the young Molé, who had been taken to Switzerland and then to England, returned to France in 1796. His *Essais de morale et de politique* (1806), justifying monarchical government, won the approval of Napoleon, who made him auditor to the council of state in 1806, prefect at Dijon in 1807, councilor of state and director of bridges and highways, with the title of comte, in 1809 and minister of justice in 1813. A peer of France on Louis XVIII's second Restoration (1815), Molé was minister for the navy under the duc de Richelieu from 1817 to 1818. Subsequently he supported the liberal monarchist opposition to the comte de Villèle.

When the July revolution of 1830 had made Louis Philippe king, Molé was minister of foreign affairs from Aug. to Nov. 1830. In Sept. 1836, however, the king made him prime minister and minister of foreign affairs. Guizot's withdrawal from the cabinet made a new formation necessary (April 15, 1837), but the king retained Molé. The ministry strengthened France's hold on Algeria, achieved a satisfactory solution of the Belgian question and sought conciliation at home, but was increasingly attacked, even by the most convinced Orleanists, as the mouthpiece of the king's personal policy. When the electorate rejected this policy in March 1839, Molé resigned. When revolution broke out in 1848, Louis Philippe again asked Molé to form a ministry (Feb. 23), but this proved impracticable.

As deputy for the Gironde in the assemblies after the revolution, Molé was a member of the "party of order" and favoured Louis Napoleon's candidature for the presidency of the republic. On the *coup d'état* of Dec. 1851 he retired from public life. He died at Champlâtreux, Seine-et-Oise, on Nov. 23, 1855.

(JE. V.)

**MOLÉ, MATHIEU** (1584–1656), French magistrate venerated for probity in an age of timeserving and faction, was the son of Edouard Molé, who as *procureur-général* was conspicuous for loyalty to the crown during the Holy League's ascendancy in Paris. He became *procureur-général* himself in 1614. During Richelieu's ministry he protested against the government's arbitrary procedures and interceded forcefully for the abbé de St. Cyran (Jean Duvergier de Hauranne) on his arrest in 1638. Richelieu then commented with kindly irony on Molé's single-minded integrity and, in 1641, rewarded it by making him premier president of the Paris *parlement*. St. Cyran's release in 1643 was largely due to Molé, who, however, had no inclination to the abbé's doctrines.

As premier president, Molé was faced with crisis after crisis during the Fronde (*q.v.*), when his respect for the royal authority and his contempt for self-interested agitators conflicted tragically both with his determination to uphold the rights of the *parlement* and with his family's affection for the house of Condé. The graybeard Molé's sardonic courage in the face of hostile mobs caused the cardinal de Retz, politically an opponent of his, to describe him as one of the three most intrepid men of his time. Anne of Austria and Mazarin were often exasperated by his rectitude but saw his merit. On April 3, 1651, Anne made him keeper of the seals. Though the seals had to be withdrawn from him on April 13 (because the duc d'Orléans objected to the appointment), Molé received them back on Sept. 8, when Louis XIV had come of age. Having gone to join the king on his travels in Dec. 1651, he re-

sumed his functions as premier president at Pontoise and returned with the *parlement* to Paris in Oct. 1652, but resigned the premier presidency, as incompatible with his tenure of the seals, in April 1653. He died in Paris on Jan. 3, 1656. (J. G. R.-S.)

**MOLE,** in zoology, any member of the mammalian family Talpidae, order Insectivora, all of which are highly modified for burrowing; also, loosely, species of the insectivore family Chrysochloridae, the Cape golden moles. In a much wider sense the term is used for the Asiatic zokors, Mediterranean mole rats, African strand "moles" (all rodents) and the Australian pouched "moles" (marsupials).

The true moles, the talpids, may be distinguished from the closely related shrews by the presence of a complete bony arch (jugal or malar arch) beneath the eye, the arch being lacking in shrews. Typical species include the common European mole (*Talpa europaea*) and the North American eastern mole (*Scalopus aquaticus*). These animals both have a cylindrical body about six inches long and a one-inch tail. They are strictly burrowers and have powerful, laterally-placed, paddlelike forelimbs; minute eyes and inconspicuous ears; a pointed muzzle; and soft, short, erect, gray-to-black fur with a singularly velvetlike texture.

Moles construct elaborate two-level burrow systems in which they spend most of their lives. The deeper level is the dwelling area; the upper level consists of temporary feeding burrows. True moles favour moist friable soil and do not live in dry areas where the soil is hard packed. The mole "swims" through loose soil so close to the ground surface that the course of the burrow is indicated by up-heaved ridges. The diet consists mainly of earthworms, grubs, insects and other small animals. The mole is a voracious eater, and if deprived of food succumbs in about 12 hours; it normally eats one-third to two-thirds of its own weight daily. In *Talpa* and *Scalopus* the male and female live separately most of the time, coming together to mate in March; the four to six well-developed young are born about six weeks later, and in two months are of adult size.

Moles are sometimes regarded as nuisances because they occasionally eat plant bulbs and roots and disfigure lawns with their burrows and open "molehill" vents. They may be caught in specially made mole traps, or killed by fumigants or poisoned baits. They are not so noxious as usually regarded; they serve a useful purpose in aerating the soil and controlling potentially harmful soil insects, and are important fur-bearers in some areas. A number of mammals and rapacious birds that are not discouraged by the moles' strong, musky odour, prey on them. Most moles swim readily and seem not to object to partially flooded burrows.

In North America the eastern mole occurs over the United States as far west as eastern Wyoming; the western moles (*Scapanus latimanus* and others) occur along the west coast. The latter are larger than the eastern mole, measuring overall as much as nine inches. The tiny shrew-mole (*Neurotrichus gibbsii*) of the Pacific northwest prefers a forest habitat, unlike most of the larger moles. The hairy-tailed mole (*Parascalops breweri*), of the northeastern United States and nearby parts of Canada, is a social species. The curious star-nosed mole (*Condylura cristata*), with 22 fleshy, pink, sensitive appendages surrounding the nose, is an expert swimmer and often ventures from its burrow.

STAR-NOSED MOLE (CONDYLURA CRISTATA) FOUND IN EASTERN CANADA AND NORTHEASTERN UNITED STATES

NORTH AMERICAN EASTERN MOLE (SCALOPUS AQUATICUS) AT ENTRANCE OF LOWER DWELLING BURROW

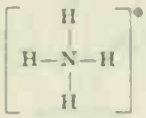
Among the number of aberrant talpid moles occurring in Asia are the eared moles of China and Japan (*Uropsilus*), the furry-snouted moles of Japan (*Dymecodon*), the club-tailed moles of southern Asia (*Euroscaptor*), the small Temminck's moles of eastern Asia (*Mogera*) and the Siberian musk moles (*Scaptochirus*). No true moles are found in South America, Africa or Australasia. *See* INSECTIVORE. (K. R. KN.)

**MOLE,** known in medicine as a pigmented nevus, is a skin blemish that either may be present at birth or may develop later in life. The yellow-brown to black colour of the mole is due to the presence of melanocytes, cells that form the pigment melanin. (*See* SKIN: *Skin in Man.*) Moles may be flat or raised, smooth or rough, hairy or hairless, large or small. In medicine they are classified into three types—intradermal, junctional and compound.

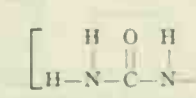
The intradermal or common moles occur in the dermis or corium. They seldom become malignant.

In junctional moles, the nevus cells are located at the junction of the epidermis and dermis. Highly malignant tumours called melanomas develop in rare instances from junctional moles, usually starting with a proliferation of melanocytes at the dermo-epidermal junction. Junctional nevi upon the palms, soles and genitalia may be forerunners of melanoma and usually should be removed as a prophylactic measure. Junctional moles occur more frequently in childhood than do the other two types but these usually mature and change to intradermal moles in adulthood. Junctional moles usually are hairless but become hairy as they change to the intradermal type. The third type of mole is the compound, which is a combination of intradermal and junctional types. Malignant melanomas may arise from the junctional portion of a compound mole. Clinical signs that suggest malignant change are growth of the mole, increased depth of pigmentation, a tendency to form scabs or to bleed, or the development of smaller satellite moles. Moles suspected of being malignant should be excised surgically. Almost every person has some moles, which are considered to be atavistic remnants of tactile sensory organs. Another type of nevus is the birthmark (*q.v.*). *See* SKIN, DISEASES OF. (G. C. AN.)

**MOLECULAR REARRANGEMENTS** are chemical processes which result in changes in the basic arrangements of bonds between atoms in molecules. A historically important example is the conversion of ammonium cyanate ($NH_4^+OCN^-$) to urea ($NH_2CONH_2$) which was discovered by F. Wöhler in 1828. Ammonium cyanate is an ionic substance, analogous to sodium chloride, comprised of a positive ammonium ion having four hydrogens attached by covalent bonds to nitrogen

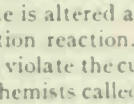


and a negative cyanate ion with oxygen and nitrogen attached to carbon in a linear fashion $[O{-}C{\equiv}N]^-$. When ammonium cyanate is heated, the ammonium ion adds to the carbon-nitrogen double bond of cyanate ion and affords urea, a nonionic substance with a very different arrangement of bonds between the several atoms



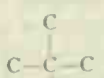
The ammonium cyanate–urea rearrangement is historically important as the first example of the conversion of a typical inorganic compound to a typical organic compound but is hardly representative of the types of molecular rearrangements of current interest.

Molecular rearrangements can be divided for practical purposes into two simple classes. In the first class are those rearrangements, such as the ammonium cyanate–urea conversion, which involve no change in molecular formula but only changes in arrangements of the chemical bonds between atoms. Since different chemical species with the same molecular formula are called isomers, this kind of rearrangement may be called isomerization—the conversion of one isomer to another. In the other class of rearrangements, the basic arrangement of the bonds between atoms in a molecule is altered as an adjunct to a substitution, elimination or addition reaction. Rearrangements of this latter type may be said to violate the customary working hypothesis of practicing organic chemists called the principle of minimum structural change. These concepts are well illustrated by specific examples from the classical researches of F. C. Whitmore on the reactions of neopentane and neopentyl derivatives. Neopentane has a central carbon atom bonded to four $CH_3$— or methyl groups, as they are commonly called.



neopentane

Substitution reactions are available for replacement of the hydrogens of the methyl groups of neopentane by a variety of different atoms or groups. The principle of minimum structural change suggests that such processes should not be accompanied by any change in the arrangement of carbon–carbon bonds in the neopentane skeleton.

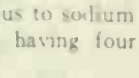


neopentane carbon skeleton

This is found to be true for many but not all substitution reactions. Thus, the following sequence of substitutions at one carbon of the neopentane molecule occurs without detectable rearrangement of the carbon skeleton.

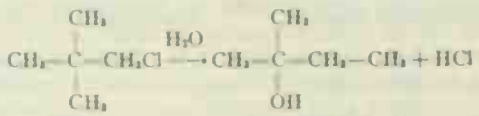
$$RCH_3 \rightarrow RCH_2Cl \rightarrow RCH_2MgCl \rightarrow RCH_2CO_2H \rightarrow RCH_2NH_2$$

(Here is abbreviated the $(CH_3)_3C$— part of neopentane to R, and $RCH_3$ is then neopentane.) However, other reactions and, particularly, all attempts to convert $RCH_2Cl$ or $RCH_2NH_2$ to $RCH_2OH$ give rearrangements of the neopentane skeleton and formation of substitution products of isopentane.



isopentane carbon skeleton

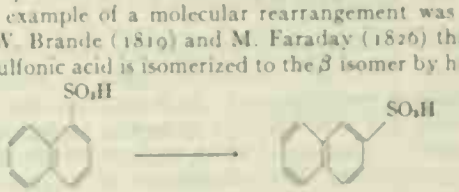
Thus,



Fortunately for the synthetic organic chemist, relatively few reactions result in carbon skeleton rearrangements so that it is usually possible to carry out a long sequence of transformations with reasonable assurance that the backbone of the molecule will remain unaltered. The neopentane system, however, is particularly prone to rearrange. This predilection for rearrangement can be used as a test for the general propensity of a given type of reaction to give rearrangement products according to whether or not rearrangement is observed with neopentyl derivatives. Cyclopropylcarbinyl derivatives, $(CH_2)_2CHCH_2X$, with X as the replaceable group, provide a still more sensitive test for possible rearranging substitutions since the carbon skeleton of such compounds is extraordinarily easily converted to that of the isomeric cyclobutyl derivatives $(CH_2)_3CHX$.

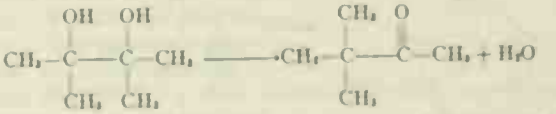
The classification of molecular rearrangements into isomerizations and rearranging substitution, elimination or addition reactions is one of practical convenience and can hardly be rigorous. Indeed, isomerization at some intermediate stage characterizes all substitution, elimination or addition reactions which result in a change in carbon skeleton. In practice, an over-all isomerization is usually easily recognized since the starting material and product have the same molecular formula but different physical and chemical properties. It is often much more difficult to establish that rearrangement has occurred in a substitution, elimination or addition reaction because there will be an over-all change in chemical composition, as well as a change in physical and chemical properties.

An early example of a molecular rearrangement was the discovery by W. Brande (1819) and M. Faraday (1826) that naphthalene-$\alpha$-sulfonic acid is isomerized to the $\beta$ isomer by heating

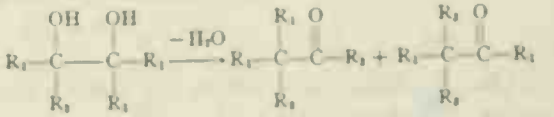


naphthalene-$\alpha$-sulfonic acid  naphthalene-$\beta$-sulfonic acid

An important general type of rearrangement was observed by R. Fittig (1860) when he found pinacol to be converted to pinacolone by elimination of water.



Much research has been done with symmetrically substituted pinacols to determine the relative "migration aptitudes" of various types of groups. Thus, for the reaction,



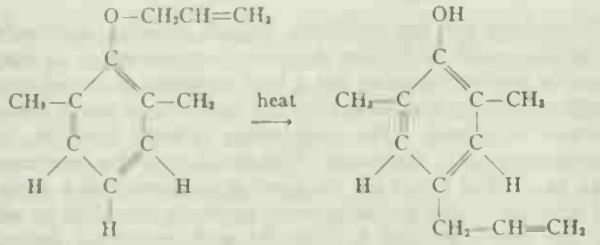
the ratio of the two possible products may be said to represent the ratio of the relative migration aptitudes of $R_1$ and $R_2$. Unfortunately ratios of migration aptitudes obtained in this way do not always carry over well to other types of rearrangement reactions.

The rearrangements discussed so far are all examples of "1,2-shifts" which can be written in the general form. R—A—B—X ⟶ X—A—B—R, where R and X are groups which exchange positions on the adjacent atoms, A—B. Many types of rearrangements are known involving shifts of groups between nonadjacent atoms. The facile isomerization of α-methylallyl bromide to γ-methylallyl bromide is an example of a 1,3-shift.

$$CH_2{-}CH(Br){-}CH{=}CH_2 \longrightarrow CH_3{-}CH{=}CH{-}CH_2{-}Br$$

α-methylallyl bromide — γ-methylallyl bromide

The *para*-Claisen rearrangement of 2,6-dimethylphenyl allyl ether is a 1,5-shift.



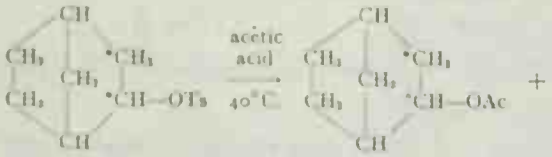
2,6-dimethylphenyl allyl ether — 2,6-dimethyl-4-allylphenol

The study of molecular rearrangements has been greatly facilitated by the use of isotopic atoms as tracers to find out which atom of a starting material becomes a particular atom of the product. For example, isotopically labeled carbon has been used to show that the Wolff rearrangement of α-diazoketones to carboxylic acids actually proceeds with a change in carbon skeleton. In this case, carbon atoms of mass 13 ($C^{13}$) were used to label the carbonyl (C=O) carbon atoms of phenyl diazomethyl ketone to distinguish them from the other ordinary $C^{12}$ carbon atoms in the molecule.

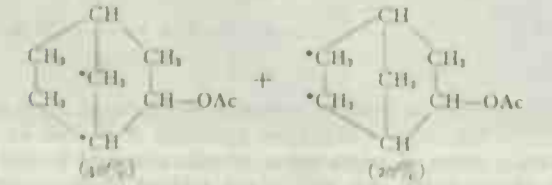
$$C_6H_5C^{*}{-}CHN_2 \xrightarrow[H_2O]{\text{heat}} C_6H_5{-}CH_2{-}C^{*}(=O){-}OH + N_2$$

$C^{13}$-labeled phenyl diazomethyl ketone
(C* indicates position of labeled atom)

The reaction product was found to have all of the $C^{13}$-label in the carboxyl (−$CO_2H$) carbon as would be expected for a carbon-skeleton rearrangement. In some cases, the use of isotopic tracers has revealed very extensive carbon-skeleton rearrangements in reactions of which might otherwise appear to be simple substitutions. The substitution of an acetoxy group (−OAc) for the *p*-toluenesulfonate group (−OTs) of carbon-labeled norbornyl *p*-toluenesulfonate affords a striking example of substantial carbon-skeleton rearrangement under exceptionally mild conditions.

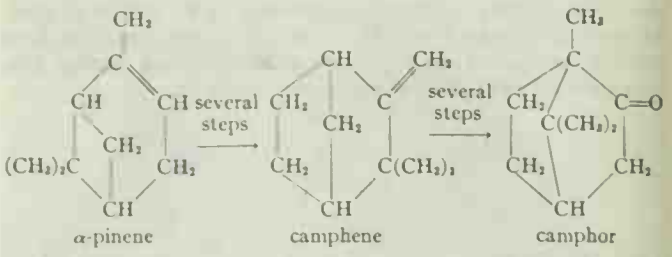


norbornyl *p*-toluenesulfonate — normal product (40%)



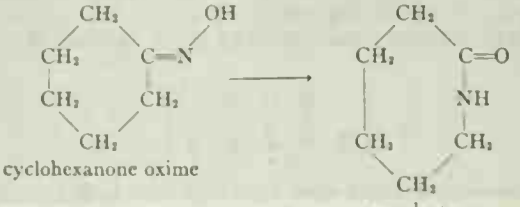
rearranged products (60%) (20%)

A number of molecular rearrangements are key steps in large-scale industrial syntheses. The conversion of α-pinene (derived from turpentine) to synthetic camphor by way of camphene involves a plethora of 1,2-shifts from carbon to carbon.



α-pinene — camphene — camphor

Rearrangement of cyclohexanone oxime to ε-caprolactam is a simple 1,2-shift from carbon to nitrogen. The product is easily convertible into a high polymer

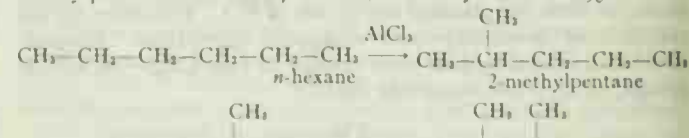


cyclohexanone oxime — ε-caprolactam

with nylonlike properties. Hydrazobenzene is isomerized by acid in a 1,10-rearrangement to benzidine which is a valuable dye intermediate.

hydrazobenzene — benzidine

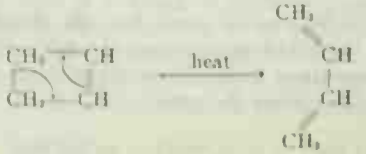
Rearrangement of straight-chain petroleum hydrocarbons to their branched-chain isomers is carried out on a large scale as a means of upgrading gasoline for use in high-compression engines. Branched-chain hydrocarbons have superior antiknock properties as compared with the corresponding straight-chain compounds. Thus, the isomerization of *n*-hexane with the aid of aluminum chloride to a mixture of 2- and 3-methylpentanes and 2,3-dimethylbutane gives a large increase in octane rating since *n*-hexane has an octane rating of only 26, whereas the methylpentanes are near 70 and 2,3-dimethylbutane is 93.



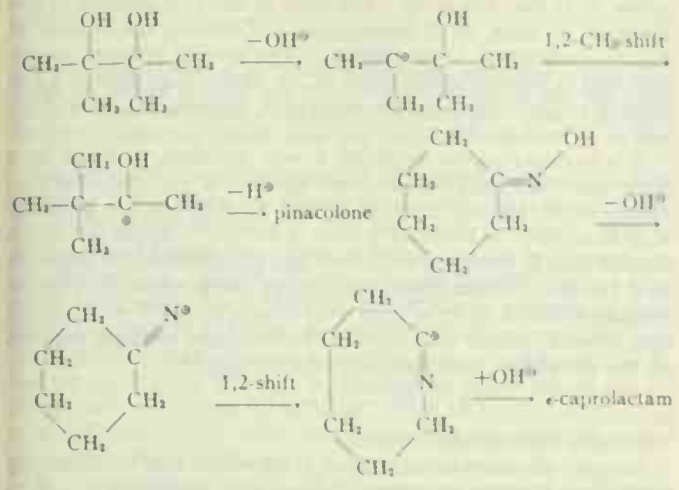
*n*-hexane — 2-methylpentane — 3-methylpentane — 2,3-dimethylbutane

Much progress has been made in the study of the mechanisms by which molecular rearrangements take place. No one mechanism or type of mechanism will suffice for the correlation of all rearrangements. This conclusion is in accord with the finding that rearrangements may be induced by agents as diverse as strong acids, strong bases, free-radical catalysts, heat and electromagnetic radiation. Key steps for several types, given below, illustrate the difficulty of producing any satisfactory single theory of rearrangements as often attempted in the past.

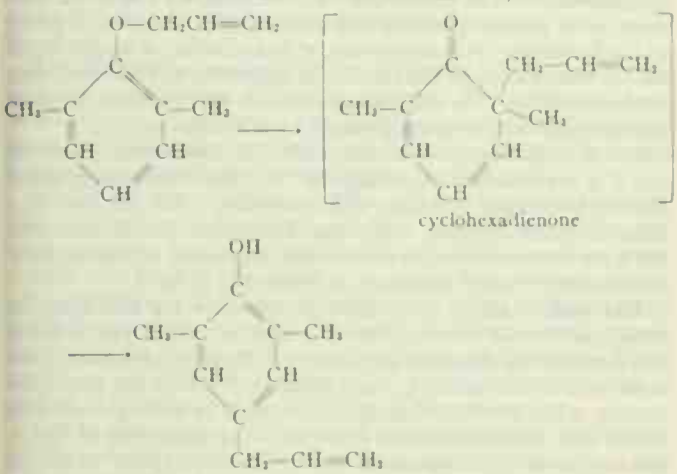
The conversion of naphthalene-α-sulfonic acid to the β isomer is a dissociation-resubstitution process with naphthalene and sulfuric acid as the intermediates. The thermal isomerization of cyclobutene to butadiene is a simple monomolecular process involving merely a rearrangement of the bonds in the molecule.



The pinacol–pinacolone and cyclohexanone oxime–caprolactam rearrangements involve loss of $OH^{\oplus}$ (with the aid of a strong acid) and 1,2-shifts of the resulting cationic species.



The *para*-Claisen rearrangement has been shown to proceed by way of an unstable cyclohexadienone intermediate so that the over-all 1,5-shift is the result of two successive 1,3-shifts.



The formation of *m*-cresol from the high-temperature alkaline hydrolysis of *p*-chlorotoluene is believed to be the result of an elimination-addition process with a "benzyne"-type substance as a transitory intermediate.

**MOLECULAR SPECTRA.** Through a spectroscope, the light from the flames of many reacting gases (*e.g.*, the blue cone of a gas flame burning in air) appears as a discrete set (spectrum) of bright lines or bands, and not as a continuous band containing all wave lengths over a wide range. The simplest spectroscope consists of an entrance slit, a collimating lens to give parallel rays which fall on a prism, and a second lens to view the spectrum (see SPECTROSCOPY). Line spectra, made up of discrete lines of no obvious pattern, arise from free atoms, and band spectra derive from molecules of two or more atoms. The study of molecular spectra has done much to clarify molecular structure, and is important in physics, chemistry and such fields as astrophysics and thermodynamics.

Molecular spectra may be observed over a range of wave lengths from 1 cm. down to about $10^{-5}$ cm. or 1000 Angstrom units (A). For the long wave lengths, monochromatic radar pulses are passed through the gas in a tube (wave guide) and the power output is measured for different input frequencies; at an absorption-line frequency of the gas the power drops, since there some input is absorbed. In the infrared region ($10^{-2}$ to $10^{-4}$ cm.) continuous radiation is passed through a cell containing the gas. The radiation is then dispersed by a prism of rock salt (NaCl) or sylvite (KCl), or by a grating. Rotation of the prism or grating allows different wave lengths to fall on a detector that records the intensity of the radiation and so gives a picture of the absorption spectrum. For wave lengths less than about $10^{-4}$ cm. detection may be by photoelectric recorders (especially for quantitative measurements of intensity), but generally is by photographic plates. These integrate the energy falling on them, so that very weak sources may be studied, even the light of the night sky. Instruments are of two kinds: those of high light-gathering power but rather low resolution, for weak sources; and those of high resolving power. In this region lines differing in wave length by 2 parts in 1,000,000 may be resolved. Visible light ranges from about 7000 A in the red to about 4000 A in the violet. Spectra in the near ultraviolet from 4000 A to 2000 A present no special problem, except that below 3500 A ordinary glasses are poor transmitters, so that prisms and lenses are made of quartz, usable down to 1900 A. But the gelatin of photographic emulsion begins to absorb at 2300 A and atmospheric oxygen at 1800 A. Below 1900 A (in the Schumann region) special plates or detectors must be used and spectrographs must be free of air.

Down to wave lengths of about 12000 A, absorption spectra have so far been the most important. Below that, emission spectra are of equal interest; among sources studied are arcs, flames, electric discharges through gases and vapours, and celestial objects (*see* SPECTROSCOPY, ASTRONOMICAL).

Molecules exist in well-defined energy levels; spectral lines arise when a molecule jumps from one such level to another. The frequency $\nu$ (in $sec^{-1}$) of radiation emitted or absorbed in a jump from a state of energy $E_1$ to one of energy $E_2$ is given by $h\nu = E_1 - E_2$, where $h$ is Planck's constant.

A molecule has (1) energy of translational motion, with levels that lie close together and are unimportant in what follows; (2) rotational energy; (3) vibrational energy (the molecule can be considered as a system of atomic point masses linked by springs); (4) energy due to the arrangements and velocities of its electrons. Possible energy levels of the last three kinds are generally more and more separated, in the order given.

The rotational energy states of a simple diatomic molecule, such as hydrogen chloride (HCl) are given approximately by

$$E_{rot} = BJ(J+1)$$

$J$ is a quantum number, taking the values $J = 0, 1, 2, 3 \ldots$ and

$$B = h^2/8\pi^2\left(\frac{m_H + m_{Cl}}{m_H \cdot m_{Cl}}\right)r^2,$$ where

$m_H$, $m_{Cl}$ are the masses of the hydrogen and chlorine atoms re-

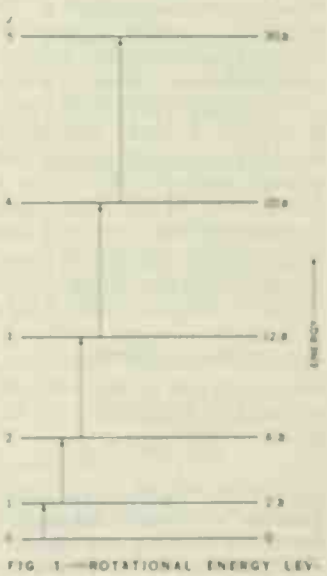

FIG. 1.—ROTATIONAL ENERGY LEVELS FOR A DIATOMIC MOLECULE. THE VERTICAL ARROWS REPRESENT TRANSITIONS THAT GIVE RISE TO THE ROTATIONAL SPECTRUM ILLUSTRATED IN FIG. 2

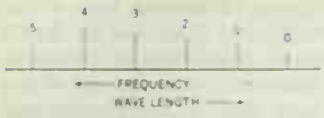

FIG. 2.—A PURE ROTATION SPECTRUM. THE NUMBERS ABOVE THE LINES REPRESENT THE VALUE OF $J$ FOR THE INITIAL STATE OF THE TRANSITION

spectively, and $r$ is the distance between them. Transitions between the energy levels, with absorption or emission of radiation, are limited to those in which $J$ changes by $\pm 1$, as in fig. 1, so that the rotation spectrum of such a molecule may be represented as in fig. 2: it consists of a series of lines, each separated by about $2B$ in energy from its neighbour. Spectra of this kind were first reported in 1927. The values of the moments of inertia for ordinary molecules are such that $B$, in frequency units, is commonly of the order of $10^{10}$ sec.$^{-1}$. Since the wave length $\lambda$ is related to the frequency $\nu$ by $c = \nu\lambda$, where $c$ is the velocity of light ($3 \times 10^{10}$ cm.sec.$^{-1}$), the wave length corresponding to $\nu = 10^{10}$ is about 3 cm. Apart from pioneer work at rather shorter wave lengths, no studies of the pure rotation spectra of molecules were possible until the development of radar techniques. These provide convenient sources of radiation at wave lengths corresponding to the energy jumps of molecules from one rotational state to another, and microwave spectroscopy became prominent from 1945 onward.

From the measured energy separation between two rotational levels and the values of the quantum number $J$, the value of the moment of inertia of the absorbing molecule can be found. Since frequencies may be measured with great precision in the microwave region, moments of inertia and, hence, interatomic distances in molecules (which are of the order of $1 \times 10^{-8}$ cm.) may be measured with high accuracy. Further, since the resolving power (the capacity to separate lines lying close together in the frequency scale) in microwave techniques may be high, it is possible to study fine details of rotational spectra arising, for example, from isotope effects, the interactions of electronic and nuclear motion, and the asymmetry of electrical charge in the absorbing molecules.

At shorter wave lengths, that is, higher energies, lie spectra which arise from simultaneous changes in rotational and vibrational energy ($\lambda = 10^{-2}$ to $10^{-4}$ cm.). Vibrations in molecules are often like those of the simple harmonic oscillator, for which the energy levels are

$$E_{v1b} = hc\omega(v + \tfrac{1}{2})$$

where $\omega$ is a characteristic frequency, here in cm.$^{-1}$ units, and $v$ is a quantum number, taking the values $v = 0, 1, 2 \ldots$. For a polyatomic molecule containing $N$ atoms, there will in general be $(3N - 6)$ such frequencies; for a diatomic molecule, there is only one frequency corresponding to vibration of the two atoms along their line of centres. In this case, the molecule has a single set of equidistant vibrational energy levels, neighbours being separated by $\omega$ cm.$^{-1}$. A transition between the rotational levels of two vibrational levels is called a vibration-rotation band. The structure of such a band is illustrated in fig. 3. The number of observable transitions is limited: commonly the rule is either $\Delta J = +1$, or $\Delta J = 0, \pm 1$.

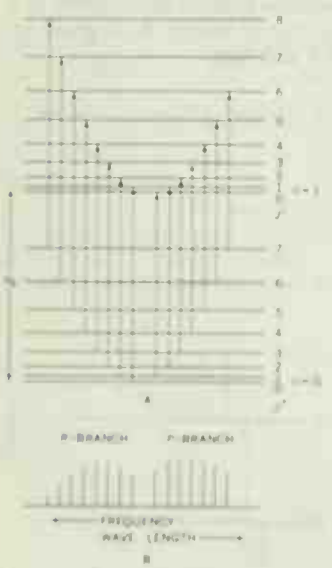

FIG. 3.—A VIBRATION-ROTATION BAND OF A DIATOMIC MOLECULE. THE ENERGY LEVELS AND TRANSITIONS (IN ABSORPTION) ARE ILLUSTRATED IN (A), AND THE APPEARANCE OF THE BAND IN (B). $\nu_0$ REPRESENTS THE DIFFERENCE IN ENERGY BETWEEN THE VIBRATIONAL LEVELS $v = 0$ AND $v = 1$

Consider an absorption band in which molecules initially in rotational states $J''$ in the vibrational level $v = 0$ absorb quanta of radiation and go into rotational states $J'$ in the vibrational level $v = 1$. A molecule in the level $J'' = 1$ may go either to $J' = 0$ or $J' = 2$, assuming the case $\Delta J = \pm 1$. The former transition gives rise to the line $P(1)$, the latter to $R(1)$, numbering according to the $J$-value of the lower level. Similarly the transition $(J' = 10) \leftarrow (J'' = 9)$ gives rise to the $R(9)$ line, and so on. The band in this case consists of two branches of lines, an $R$-branch and a $P$-branch, the former at higher, the latter at lower energies. The spacing between successive lines is approximately equal to $2B$, except that there is a line missing at the origin, for the separation between the lines $R(0)$ and $P(1)$ is about $4B$.

A vibration-rotation band of a real diatomic molecule is a little more complex than described above, for (1) the rotational energy levels are not those of a rigid rotator, but are given by $E_{rot}/hc = BJ(J+1) - DJ^2(J+1)^2 + \ldots$, where $D$, much smaller than $B$, expresses the centrifugal expansion of the molecule as it rotates; (2) the vibrational energy levels converge with increasing $v$, thus $E_{v1b}/hc = \omega_e(v + \frac{1}{2}) - x_e\omega_e(v + \frac{1}{2})^2 + \ldots$ where $x_e\omega_e$ is much smaller than $\omega_e$; (3) the rotational constant depends on the vibrational quantum number according to

$$B_v = B_e - \alpha(v + \tfrac{1}{2}) + \ldots$$

where $\alpha$ is much smaller than $B_e$.

In a real vibration-rotation band, these effects lead to decreasing separations between successive $R$ lines with increasing $J$, and to increasing separations between successive $P$ lines with increasing $J$. In such a band (as in fig. 3), the heights of the lines are roughly proportional to their intensities. The intensity of a spectral transition is in general given by the product of a constant, a power of the frequency ($\nu^1$ in absorption, $\nu^4$ in emission), a weight factor for the transition, and the number of molecules in the initial state of the transition. In thermal equilibrium, this number decreases exponentially with increasing energy by a Boltzmann term $e^{-E/kT}$, where $E$ is the energy (per molecule), $k$ is Boltzmann's constant, and $T$ is the absolute temperature in °K. Since the weight factor for the transitions increases with increasing $J$ for the lines in a vibration-rotation band, while the Boltzmann factor decreases, there are observed maxima of intensity, dependent on the temperature, in the $R$- and $P$-branches, as illustrated in fig. 3.

The weight factors for a diatomic molecule are zero both for pure rotation and vibration-rotation spectra, unless the molecule has electrical or magnetic asymmetry. Thus homonuclear molecules such as nitrogen ($N_2$) and chlorine ($Cl_2$) do not give these spectra, while heteronuclear molecules such as hydrogen chloride (HCl) and carbon monoxide (CO) do. The intensities of the vibration bands in absorption, $v' \leftarrow v''$, fall very rapidly in the sequence $1 \leftarrow 0$, $2 \leftarrow 0$, $3 \leftarrow 0 \ldots$.

Most of the information derived from the study of vibration spectra in the infrared region has been obtained from measurements of the position of the lines: these give the structural constants, particularly $B$, $D$, $\omega_e$ and $x_e\omega_e$, which in turn provide detailed information about molecular architecture and molecular mechanics. The absolute intensities of spectral transitions are more difficult to measure and less easily interpreted. But relative intensities are very useful in quantitative analysis, for the infrared spectrum of a molecule is a highly characteristic property—a molecular fingerprint. From what was formerly the special equipment of a few research laboratories were developed familiar tools of routine analysis in industry.

Information about the rotational and vibrational energy states of molecules may also be obtained from scattering effects. When light falls on atoms or molecules, the distribution of electrons around the nuclei may be somewhat changed and therefore some light is scattered. It is indeed the scattering of sunlight by the atmosphere that makes the sky blue, as Lord Rayleigh showed. This classical effect, explicable without quantum theory and now called Rayleigh scattering, occurs without change of wave length. Molecules may also show a much weaker, nonclassical scattering with change of wave length; this is the Raman effect (*q.v.*). It depends on how the polarizability varies during molecular rotation and vibration; since the intensities of the infrared spectra depend on different molecular properties (on the electric dipole moment) during rotation or vibration, the infrared and Raman effects are, in general, complementary.

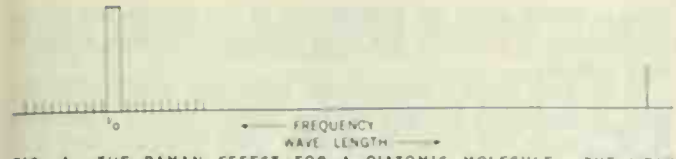

FIG. 4.—THE RAMAN EFFECT FOR A DIATOMIC MOLECULE. THE WEAK LINES ON EITHER SIDE OF THE EXCITING FREQUENCY $\nu_0$ ARE THE LINES OF THE PURE ROTATIONAL EFFECT. THE STRONGER "LINE" AT MUCH GREATER SEPARATION ARISES FROM THE VIBRATIONAL EFFECT

Suppose that the frequency of the monochromatic exciting radiation is $\nu_0$. Then the Raman effect produces scattered radiation of other frequencies, $\nu = \nu_0 \mp \Delta\nu$. Lines for which $\nu = \nu_0 - \Delta\nu$ are called Stokes lines; lines at higher frequencies than $\nu_0$ are anti-Stokes lines. The values of $\Delta\nu$ are characteristic of the scattering molecules. For a rigid rotating diatomic molecule of rotational constant $B$, the rotational Raman spectrum contains lines corresponding to the changes $\Delta J = 0$ or $+2$. For $\Delta J = 0$, $\nu = \nu_0$, but for $\Delta J = 2$, an $S$-branch is obtained on either side of the exciting line. $S(0)$ lies at $\nu_0 \pm 6B$, $S(1)$ at $\nu_0 \pm 10B$, $S(2)$ at $\nu_0 \pm 14B$ and so on. The formation and appearance of such a spectrum is illustrated in fig. 4.

At bigger separations $\Delta\nu$, the Raman spectrum of a diatomic molecule contains at least two further "lines." These are the piled up $Q$-branches ($\Delta J = 0$) of the vibrational effect; with long exposures, lines of the $S$-branches may also be seen. Neglecting this rotational structure, $\Delta\nu \sim \omega$, or, more exactly, $\Delta\nu = \omega_e - 2x_e\omega_e$.

Raman spectra—particularly the rotational effects—are of low intensity and therefore difficult to observe. The techniques were, however, greatly improved from 1955 onward, and the closely spaced rotational Raman spectra of molecules, even as heavy as benzene, were satisfactorily resolved by the late 1950s.

Finally, there are electronic spectra. If two atoms are far apart, their interaction is negligible; if they are brought sufficiently close together, the electron-electron and nucleus-nucleus interactions will lead to repulsion (*i.e.*, atoms are to some extent incompressible). At intermediate distances either the atoms interact to form a stable chemical bond, with a reduction in the potential energy; or the atoms repel each other at all distances. These two cases are illustrated in fig. 5, in which potential energy is plotted as a function of the interatomic separation.

Just as electrons may be arranged around the nuclei of atoms in different ways to give states of different electronic energy, so also with molecules, and electronic spectra arise by transitions between the rotational and vibrational states of two different electronic states of a molecule. Since such states are often quite widely separated in energy, the transitions occur at wave lengths between about $10^{-4}$ to $10^{-5}$ cm or 10000 to 1000 Å (1Å = $10^{-8}$ cm); this range includes visible light from violet at about 4000 Å to red at 7000 Å. Such a transition is called an electronic band system. For example, such a transition between two electronic states gives chlorine gas its green-yellow colour, iodine vapour its purple colour, and it is a transition in ozone that makes the earth habitable, by absorbing the sun's ultraviolet radiation at wave lengths below about 3000 Å.

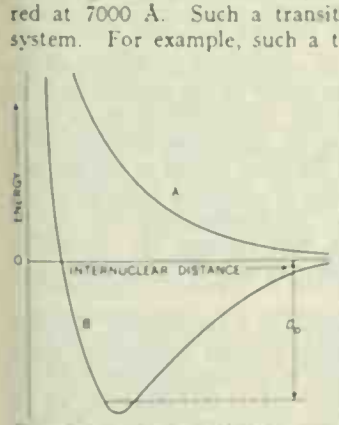

FIG. 5.—POTENTIAL ENERGY AND DISTANCE FUNCTIONS FOR DIATOMIC MOLECULES. (A) SHOWS THE FORMATION OF A STABLE MOLECULE, WITH DISSOCIATION ENERGY $D_0$. (B) SHOWS REPULSION. NO STABLE MOLECULE IS FORMED

The appearance of an electronic band system of a diatomic molecule depends upon the values of the constants $\omega''$, $\omega'$, $B''$, $B'$, the vibrational and rotational constants for lower ($''$) and upper ($'$) states. Selection rules (of the kind $\Delta J = \pm 1$ or 0) limit the number of rotational transitions, but the vibrational transitions depend upon the relative orientations of the potential energy curves for the upper and lower electronic states. Two possibilities are illustrated in fig. 6(A) and 6(B). Roughly, it can be said that electronic rearrangements are swift compared with nuclear motion, so that transitions which can be represented by vertical lines in potential energy diagrams are the most probable.

If the minima of the potential energies for upper and lower states happen to occur at about the same internuclear distance (fig. 6[A]) then it is found that most of the intensity of the system is concentrated into the rotational transitions associated with the changes in vibrational levels from $0 \leftrightarrow 0$, $1 \leftrightarrow 1$, $2 \leftrightarrow 2$ and so on. If, however, there is a big difference between the values of the internuclear distances at the minima, then the most probable vibrational transitions are from high $v'$ to low $v''$ and from low $v'$ to high $v''$, and the $0 \leftrightarrow 0$ band may be too weak to be observed. How closely the vertical lines are spaced depends on the rotational constants $B'$ and $B''$, which are in turn determined by the moments of inertia. Light molecules give bands of open structure; heavy ones, bands of structure sometimes irresolvably close. Because of interaction between electronic and nuclear motion, the expressions for energy levels are in some cases more complicated than the rigid rotator formulas; a band may thus have more than the two or three branches mentioned above. In some cases the positions of the vibrational energy levels of a particular electronic state may be followed to high values of the vibrational quantum number.

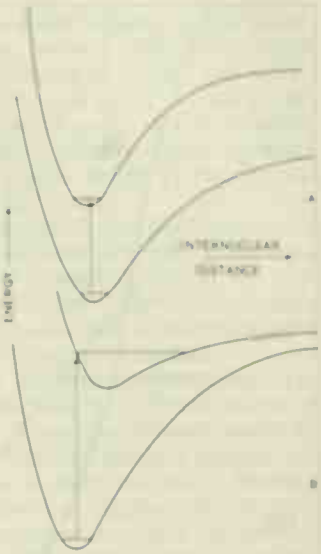

FIG. 6.—TRANSITIONS BETWEEN ELECTRONIC STATES OF DIATOMIC MOLECULES. IN (A) $R'_e = R''_e$; IN (B) $R'_e > R''_e$. VERTICAL ARROWS REPRESENT THE STRONGEST TRANSITIONS IN THE ABSORPTION SPECTRUM

The intervals between successive vibrational levels decrease with increasing value of $v$, and it may be possible to extrapolate to the point at which the interval becomes zero (*see* fig. 7). On the potential energy diagram, this corresponds to the limit for two noninteracting atoms at relatively large internuclear separation. The energy difference between the lowest vibrational level ($v = 0$) and the dissociation limit is called the dissociation energy, and represents the energy necessary to separate the two atoms in the normal state of a diatomic molecule to infinity. Thus, the energy required to break up the oxygen molecule ($O_2$) into two oxygen atoms, is about 120 Kcal/mole (1 mole = $6 \times 10^{23}$ molecules).

Atoms of identical nuclear charge and identical number of extranuclear electrons but differing nuclear mass are called isotopes. Thus naturally occurring oxygen ($O_2$) contains mostly atoms of relative mass 15.9994 atomic weight units ($O^{16}$) but also a small proportion of heavier atoms $O^{18}$, and a still smaller proportion of $O^{17}$ atoms. The spectra of two isotopic molecules such as those of oxygen-16 and oxygen-18 or $HCl^{35}$ and $HCl^{37}$ are not identical, for the heavier molecule has a bigger moment of inertia, and thus a smaller value of the rotational constant $B$ than the lighter one; furthermore, the characteristic vibration frequency for the heavier molecule will be less than that of the lighter one. Indeed, some isotopes were in fact first discovered by observations of their spectra, notably $O^{18}$. Such isotope effects help to clarify the spectra of polyatomic molecules.

At shorter wave lengths than can commonly be photographed in air (because of the strong absorption by oxygen) there lie spectra which, though similar to the electronic spectra, are more analogous to atomic spectra. In this region, a series of band systems converging to a high energy limit has been found for some molecules. These arise from the progressive excitation of an electron from the molecule; the convergence limit marks the point at which ionization occurs (the electron becoming detached). This may

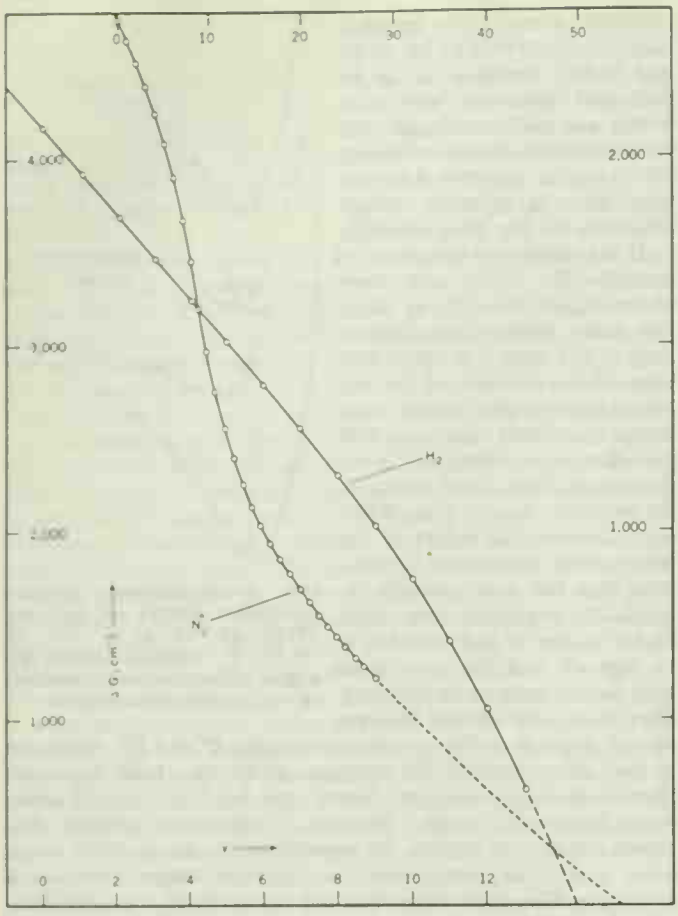

FIG. 7.—THE SEPARATIONS BETWEEN SUCCESSIVE VIBRATIONAL LEVELS PLOTTED AGAINST VIBRATIONAL QUANTUM NUMBER (1) FOR THE LOWEST ELECTRONIC STATE OF $H_2$ (LOWER AND LEFT SCALES), (2) FOR AN EXCITED STATE OF $N_2^+$ (UPPER AND RIGHT SCALES)

be written $MX \rightarrow MX^+ + e^-$. Such series are called Rydberg series.

A molecule has many different electronic states, some stable and some unstable (fig. 5). As in atomic spectra, not all possible transitions take place with measurable intensity, but a molecule may still have a large number of strong band systems. Some spectra, particularly in emission, are therefore greatly complicated by the overlapping of different systems.

Molecular spectroscopy helps to reveal molecular structure. For diatomic molecules, it indicates the size of the molecule (*i.e.*, the equilibrium internuclear distance), the characteristic vibration frequency $\omega_e$ and the energy of dissociation. For polyatomic molecules where, so far, the infrared, Raman and microwave spectra have been the most helpful (the electronic spectra of polyatomic molecules are generally very complex), in the simpler cases spectroscopy yields information about the equilibrium configuration of the molecule and about the ways in which the molecule can vibrate.

So far it has been assumed that the emitting or absorbing molecules are in the dilute, gaseous state. In going to a compressed gas and thence to the more concentrated liquid or solid states the spectra generally change, the fine structure arising from rotational changes is lost and evidence is obtained about the nature and extent of interactions between molecules.

Since the populations of molecules in different energy states are determined (in equilibrium) by their temperature, and since the intensities of spectral lines are proportional to their populations in the initial states of the quantum jumps, the measurement of relative intensities of lines may yield the temperature of the emitting molecules. Thus can be measured the temperatures of inaccessible sources, such as flames from rocket motors, the upper atmosphere (using the aurora) and stars. Most of what is known about the atmospheres of the planets and of the composition of the stars has been discovered through study of their spectra.

In the 19th century spectroscopic techniques were mainly applied to qualitative analysis through atomic spectra (following R. W. Bunsen and G. R. Kirchhoff). New elements were thus discovered, *e.g.*, cesium and thallium, and helium was identified in the sun. Little progress in molecular spectroscopy was made until a theory of the energy levels in molecules was formulated, particularly in the decade 1920–30. Intensive testing followed and confirmed the theory, which now became adequate to many problems concerning diatomic molecules.

The spectra of polyatomic molecules raise complex problems, and attracted increasing attention after 1945. Technical advances have made it possible to work out the molecular structure in some of the simpler cases. The properties of stable molecules have been found from a study of transitions between closely spaced energy levels produced by electric or magnetic fields, sometimes in molecular-beam experiments. For example, positions of hydrogen atoms in certain crystals, difficult to detect by X-ray diffraction, were located through nuclear magnetic resonance, from observed transitions between energy levels arising when nuclei with a magnetic moment are placed in a magnetic field.

Likewise, knowledge of unstable molecules was greatly advanced by the development of flash photolysis, in which products formed by rapid absorption of large numbers of quanta are examined spectroscopically at short-time intervals after the flash. Such studies are relevant to special problems of chemical reactivity in flames and combustion processes. Thus, the first definite information about the structure of the methyl radical was obtained from the flash photolysis of mercury dimethyl.

Indeed, experiment had outstripped theory by the 1960s. A quantitative theory of the structure of polyatomic molecules had yet to be found. *See* LASER; MASER.

*See* G. Herzberg, *Molecular Spectra and Molecular Structure*, vol. I of *Spectra of Diatomic Molecules* (1950); A. G. Gaydon, *Dissociation Energies and Spectra of Diatomic Molecules* (1950). (R. F. Bw.)

**MOLECULE.** The molecule may be defined, in chemistry and physics, as the smallest part of a substance that can exist free in the gaseous state while retaining the composition and chemical properties possessed by the gaseous material in bulk. From the chemical point of view, however, the foregoing definition is somewhat too restrictive, since many substances cannot be obtained in the gaseous state without partial or complete decomposition. If the concept of the molecule is to be retained for such substances, therefore, it must be generalized so that it has meaning with respect to states of matter other than the gaseous. One such generalization, which is widely adopted, is made possible by the fact that many, although not all, nonvolatile substances can be dissolved in inert solvents (*i.e.*, in solvents with which they do not react chemically). For example, many proteins are soluble in water.

The molecule of a substance can accordingly be defined as the smallest part of it that exists free either in the gaseous state or in dilute solution in an inert solvent. Ordinarily, in those cases in which a direct comparison can be made, the molecule of a given substance is found to be of the same weight in the gas and in solution; several significant types of exception exist, however, as will be mentioned again later. With substances that can be neither vaporized nor dissolved in inert solvents, the concept of the molecule loses most of its utility, as well as its meaning, and is not commonly employed.

The molecule also may be defined, in a superficially different but usually equivalent way, as either a single independent atom or an aggregate of atoms; the atoms in the aggregate are held together by relatively strong (valence) forces and therefore act as a unit. (Although, according to this definition, a molecule may consist of a single atom, as, for example, a molecule of helium or other rare gas, an unfortunate tendency has arisen in certain circles to limit the term molecule to aggregates of two or more atoms.) The relation between this definition and the preceding one can be clearly seen if it is realized that a pure substance in bulk consists

of a very large number of molecules, or aggregates of the type described, that (aside from possible variations in isotopic composition) are exactly alike and exert only relatively weak forces upon one another. Consequently, a division of a sample of the substance into progressively smaller parts produces no change in either composition or chemical properties until parts consisting of single molecules are reached. Further subdivision then leads to still smaller particles that usually differ from the original substance in composition and almost always differ from it in chemical properties because, in the last stages of the fragmentation, one or more strong valence bonds are necessarily ruptured (or, if the molecules in question consist of single atoms, these atoms themselves must be broken up).

**The Molecule in the Solid State.**—Since it has been found that atoms joined by strong valence bonds are always relatively close to one another in space, a method by which the concept of the molecule can be extended to the solid state is at once suggested. In solid naphthalene, for example, examination of the crystal structure has shown that the substance consists of identical aggregates, each composed of ten carbon and eight hydrogen atoms. In each aggregate, each atom is close to, and so must be relatively strongly bonded to, at least one other atom of the same aggregate; but no two atoms in different aggregates are comparably close to one another. Consequently, the aggregates can be regarded as identical with the individual molecules.

The molecular weight of naphthalene in the gaseous state and in solution has been measured by the procedures mentioned below; under these conditions likewise, the molecules consist of ten carbon and eight hydrogen atoms each.

Although many solid substances resemble naphthalene in that they consist of distinct molecules, the nature of many others is entirely different. Sodium chloride (common table salt) consists of sodium ions and chloride ions so arranged that each sodium ion is surrounded by six equidistant chloride ions, and each chloride ion is surrounded by six equidistant sodium ions. Hence, no distinct aggregate identifiable with a molecule of sodium chloride exists, unless each entire crystal be considered as a single molecule. Consequently, in sodium chloride, and in all other solids of similar type, the concept of the chemical molecule loses its significance. (*See* also CRYSTALLOGRAPHY; SOLID STATE PHYSICS: *Physical Properties of Solids.*)

**Molecular Sizes and Weights.**—The absolute sizes and weights of individual molecules cannot be determined by purely chemical methods; various other methods, however, have been successfully applied to the determination of both their linear dimensions and their weights. Thus, it has been shown that the lengths, or diameters, of most molecules lie between $10^{-5}$ and $10^{-7}$ cm., and that most molecules weigh between about $10^{-23}$ and $10^{-20}$ g. Some substances, such as the proteins, consist of much larger molecules, and a few consist of molecules large enough to be "seen" with the electron microscope. These are extreme cases, however; ordinarily molecules are much smaller. (*See* also PROTEINS; MICROSCOPE.)

More important chemically than the absolute weights of the individual molecules are their relative weights with respect to one another. For this purpose the weight of the hydrogen atom was originally adopted by convention as the unit in terms of which the weights of all other atoms and molecules were to be expressed. Thus, the atomic weight of hydrogen was by definition exactly 1.0000, that of oxygen was about 15.87, and so on. Subsequently, however, it was found more convenient to use, as the standard unit, one-sixteenth the weight of an oxygen atom, so that the atomic weights of hydrogen and oxygen became about 1.008 and exactly 16.0000, respectively. This second convention was replaced in 1961 by a system based on carbon-12, the principal isotope of carbon. In this system the atomic weights of hydrogen and oxygen are 1.00797 and 15.9994 respectively. (*See* ATOMIC WEIGHT.)

The weight of a molecule in terms of the foregoing conventional unit is called the molecular weight of the corresponding substance. It is numerically equal to the sum of the atomic weights of all the atoms that make up the molecule. Thus, since a molecule of oxygen contains two atoms of oxygen, the molecular weight of oxygen is 31.9988; since a molecule of water contains two atoms of hydrogen and one of oxygen, the molecular weight of water is about 18.015; and so on. If the molecular weight of a substance is M, then M grams of that substance is called a gram molecular weight, a gram molecule or, more briefly, a mole. Thus, a mole of oxygen weighs 31.9988 g; one of water weighs about 18.015 g; and so on.

It is a corollary of Amedeo Avogadro's law (*see* AVOGADRO'S CONSTANT) that the number of molecules in a mole is the same for all substances. This number (Avogadro's number or Avogadro's constant) is approximately $6.02456 \times 10^{23}$. The absolute weight of a single molecule of any substance is the weight of a mole of that substance divided by Avogadro's number.

**The Effect of Variations in Isotopic Composition.**—The discovery of isotopes established the fact that different atoms of an element may differ in weight. Therefore different molecules of a given substance may have different absolute weights and hence different molecular weights, if they are not of identical isotopic composition. From the practical chemical point of view, however, these ambiguities are unimportant, since the average atomic weight of each element is almost always found to be constant within the experimental error of measurement, regardless of the source of the element or of its state of combination. In all ordinary chemical experiments, the numbers of molecules involved are so enormous that only the average atomic and molecular weights are important. (*See* ISOTOPE: *Relationship of Chemical Atomic Weights to the Existence of Isotopes.*)

**The Determination of Molecular Weights.**—Several experimental methods have been devised for the determination of molecular weights. Of these, the most fundamental is based upon Avogadro's law, which states that equal volumes of any two gases at the same temperature and pressure contain the same number of molecules. This law, which is rigorously true only for perfect gases, is obeyed approximately by all gases and it becomes increasingly true as the pressure is decreased. Consequently, the ratio of the molecular weights of any two substances is approximately equal to the ratio of the measured weights of equal volumes of the gaseous substances at the same temperature and pressure; and the equality becomes more nearly exact as the pressure is lowered. Since the molecular weight of oxygen is by definition 31.9988, that of any other substance can be determined by comparison with oxygen. Thus, it has been found that one mole (31.9988 g.) of oxygen occupies 22.421 litres at 0° C. and 760 mm. pressure; consequently, the gram molecular weight of any other substance is seen to be equal to the weight of it in grams that would occupy 22.421 litres in the gaseous state at 0° and 760 mm. If the substance is not gaseous under these conditions, the required weight can often be calculated with the aid of the perfect gas laws from the measured density of the gas under any suitable experimental condition.

The molecular weights of substances that cannot be vaporized can often be determined in solution in an inert solvent since the lowering of the freezing point of any given solvent, the raising of its boiling point, the decrease of its vapour tension at any temperature and the osmotic pressure of the solution are all directly proportional to the number of solute molecules present in a given weight of solvent (*see* SOLUTIONS: *Thermodynamic Properties*). Consequently, the molecular weight of the solute must be inversely proportional to the magnitudes of the effects, of the types listed, produced by a given weight of it in a given weight of solvent. Since the value of the proportionality constant depends upon both the property studied and (ordinarily) the solvent used, but not upon the solute, it must be determined by comparison with some substance, the molecular weight of which has previously been determined in the gaseous state. Thus, it has been found that one mole of any solute dissolved in 1000 g. of water lowers the freezing point by 1.855° C. and raises the boiling point by 0.51° C.

As with the methods based directly upon Avogadro's law, these methods also give only approximately correct values of the molecular weights, but they become more nearly exact as the solu-

tions are made more dilute. (*See* ATOMIC WEIGHT: *Experimental Determination.*)

**Empirical and Molecular Formulas.**—The empirical formula of a substance is the simplest formula that describes its chemical composition. Thus, benzene contains 7.74% hydrogen and 92.26% carbon. Since the atomic weights of hydrogen and carbon are 1.00797 and 12.01115, respectively, and since these are in the ratio of 7.74 to 92.26, it follows that the numbers of hydrogen and carbon atoms in a molecule of benzene must be equal. The empirical formula of the substance is therefore CH.

The molecular formula of a substance describes not only the chemical composition but also the molecular weight of the substance. Thus, the molecular weight of benzene can be found by any of the above methods to be in the neighbourhood of 78, whereas the calculated weight corresponding to the unit CH is about 13.019. Evidently, therefore, the molecule of benzene must contain six such units, so that the molecular formula is $C_6H_6$. An alternative, but equivalent, definition of the molecular formula is that it is the formula that specifies the number of atoms of each element present in a single molecule of the substance in question.

**Association and Dissociation in Solution.**—As has already been mentioned, molecular weights measured in the gaseous state and in solution, although they are usually identical, may be different. Two distinct types of discrepancy are encountered; the molecular weight of a substance may be either greater or less in solution than in the gas. When it is greater, the substance is said to be associated in solution; when the weight is less, the substance is said to be dissociated. Association occurs commonly in nonpolar solvents like benzene when the molecules of the solute contain hydroxy groups (OH) or amino groups ($NH_2$). (*See* ASSOCIATION, CHEMICAL.) On the other hand, the most important type of dissociation is the electrolytic dissociation undergone by acids, bases and salts when dissolved in ionizing solvents like water.

It has been shown that, in aqueous solution, most salts and some acids and bases are almost completely dissociated into ions, but that a few salts and many acids and bases are only partially dissociated. Sodium chloride, for example, exists in aqueous solution almost entirely as a mixture of sodium ions ($Na^+$) and chloride ions ($Cl^-$); on the other hand, acetic acid exists mostly as undissociated molecules ($CH_3CO_2H$) and to only a small extent as hydrogen ions ($H^+$) and acetate ions ($CH_3CO_2^-$). If an attempt is made to measure the molecular weight of a substance in a solvent in which it is dissociated into ions, the numerical result of the experiment should correspond, ideally, to the average weight of the various ions and molecules present. Actually, however, the situation is complicated by the strong electrostatic interactions between the charged ions.

The result of these interactions is that, unless the concentration of the ions is extremely low, the effects of the solute upon the freezing point, etc., are appreciably smaller than those that would have been produced by an equal concentration of uncharged molecules. Consequently, the extent of dissociation appears to be less than it really is.

**The Determination of Very Large Molecular Weights.**—The determination of the molecular weight of a substance that has a very large molecular weight is relatively difficult. Such a substance (for example, a protein) is almost certainly nonvolatile, so the method based directly upon Avogadro's law is inapplicable. Moreover, the various methods that could be used for the determination of the molecular weight in solution are unsatisfactory, since the effects produced by the presence of the solute, being inversely proportional to its molecular weight, are very small and may be too small to be measured precisely, or even to be observed. For such substances, "minimum molecular weights," which can be obtained from analytical data, are frequently useful. Hemoglobin, the protein responsible for the red colour of blood, for example, contains about 0.335% iron. If each molecule of hemoglobin contains $n$ atoms of iron, the molecular weight of hemoglobin is easily shown to be about $16{,}700n$. Since $n$ cannot be less than one, the minimum molecular weight of the protein is therefore 16,700. Moreover, since $n$ must be an integer, the true molecular weight must be an integral multiple of 16,700. Such information is often of value in the determination of the true molecular weights.

The most generally useful methods for the determination of actual, as distinguished from minimum, molecular weights of large molecules involve the use of the ultracentrifuge. The principle underlying these methods is that when a solution of the substance is subjected to extremely great centrifugal forces the solute is forced measurably away from the centre if it is more dense than the solvent, or toward the centre if it is less dense than the solvent. The molecular weight of the solute can be calculated either from the rate of sedimentation or from the final distribution of solute after equilibrium has been reached. In this way, molecular weights of any magnitude, provided they are sufficiently large, can be determined. A more recent method, which, like the ultracentrifugal one, is restricted to the study of extremely large molecular weights, is based upon the scattering of light by solutions of the substances of interest. The principles of this method, however, are too technical to be discussed further here. If, by either of these methods, a rough value of the true molecular weight of any substance is obtained, a comparison with the minimum molecular weight often permits the derivation of a more precise value. Thus, since the molecular weight of hemoglobin, for example, must be of the form $16{,}700n$ (where $n$ is an integer), knowledge that the molecular weight lies between, say, 60,000 and 70,000 is sufficient to show that $n$ must be exactly equal to four, and that the molecular weight is approximately 66,800.

**Molecular Weights of Solids.**—If a substance is solid under ordinary conditions, and if analysis of its crystal structure shows that it consists of individual molecules, the molecular weight is, of course, simply the sum of the atomic weights of all the atoms contained in a single molecule. On the other hand, if analysis of the crystal structure shows that a given solid does not consist of individual molecules, then its molecular weight is an essentially meaningless concept. For such substances as these latter, one speaks instead of the formula weight; this is the weight corresponding to the empirical formula.

With sodium chloride, for example, the empirical formula is NaCl, even though no molecules consisting of one atom of sodium and one of chlorine are present in the solid. Consequently, since the atomic weights of sodium and chlorine are 22.9898 and 35.453, respectively, the formula weight of sodium chloride is 22.9898 + 35.453 = 58.4428. Speaking somewhat loosely, one frequently refers to 58.4428 g. of sodium chloride as constituting a mole of the substance.

(G. W. WD.)

**MOLE RAT,** the name for two distinct kinds of old world rodents:

1. A group of blind burrowing rodents typified by the large gray *Spalax typhlus* of eastern Europe, western Asia and Egypt, which represents the family Spalacidae. These mole rats are characterized by the lack of a distinct neck; they have small or rudimentary ears and eyes, short limbs provided with powerful digging claws, and a rudimentary tail. They make burrows in sandy soil, and feed on bulbs and roots. The closely related bamboo rats (*Rhizomys*) from India and Burma and *Tachyoryctes* from East Africa differ by the absence of skin over the eyes, the presence of short ears and a short, sparsely-haired tail; they burrow among tall grass, or at the roots of trees.

2. Another group is the African family Bathyergidae, which contains several genera living south of the Sahara, one of which is almost naked. These very specialized burrowers rarely come to the surface. *See* RODENT.

**MOLESKIN,** a stout, heavy cotton fabric used for purposes in which a fabric capable of resisting rough usage is desirable. *See* FUSTIAN.

**MOLESWORTH, MARY LOUISA** (1839–1921), British writer of children's stories who has been called "the Jane Austen of the nursery," was born at Rotterdam, Neth., on May 29, 1839. She was the daughter of Charles Augustus Stewart, a Scottish merchant and shipper of Manchester, where she lived until her marriage in 1861 to Major Richard Molesworth. She settled in London in 1883 and died there on July 20, 1921.

Mrs. Molesworth began her literary career in 1870 with three-volume novels of little merit. *Tell Me a Story* (1875) and *Carrots: Just a Little Boy* (1876) set her suddenly among the leading writers for children, and *The Cuckoo Clock* (1877) made that position secure. She wrote many more stories: *Two Little Waifs* (1883), *Us* (1885), *Four Winds Farm* (1887), *The Children of the Castle* (1890), *Nurse Heatherdale's Story* (1891), *An Enchanted Garden* (1892), *The Carved Lions* (1895), *The House That Grew* (1900), *Peterkin* (1902), *The Story of a Year* (1910) and *Fairies Afield* (1911) are the most perfect examples of her rare gifts as storyteller and interpreter of childhood.

*See* Roger Lancelyn Green, *Mrs. Molesworth* (1961), with short-title bibliography. (R. L. GR.)

**MOLESWORTH, SIR WILLIAM,** BART. (1810–1855), English radical politician, son of the 7th baronet, was born on May 23, 1810, in London. After succeeding to baronetcy in 1823, he studied at Edinburgh, Cambridge, Offenbach, Rome and Naples. On the passing of the Reform act of 1832 he was returned to parliament for the eastern division of Cornwall. He made the acquaintance of George Grote and James Mill, and in April 1835 founded, in conjunction with John Roebuck, the *London Review*, as an organ of the "Philosophic Radicals." After the publication of two volumes he purchased the *Westminster Review*, and for some time the united magazines were edited by him and John Stuart Mill. He sat for Leeds from 1837 to 1841, and acquired considerable influence in the house of commons by his speeches and by his tact in presiding over the select committee on transportation. But his radicalism made little impression either on the house or on his constituency. From 1841 to 1845, when he had no seat in parliament, he devoted his leisure time to editing the works of Thomas Hobbes in Latin and English, a recreation that cost him no less than £6,000. He was returned for Southwark in 1845, and retained that seat until his death. On his return to parliament he devoted special attention to the condition of the colonies, and was the ardent champion of their self-government. Lord Aberdeen included him in the cabinet in Jan. 1853 as first commissioner of works, the chief work by which his name was brought into prominence at this time being the construction of the new Westminster bridge; he also was the first to open Kew Gardens on Sundays. Molesworth was made colonial secretary in July 1855 but before he had time to implement his views he died on Oct. 22, 1855, in London. (A. BRI.)

**MOLFETTA,** an Adriatic port and episcopal see in the Puglia region of Italy, in the province of Bari, 26 km. (16 mi.) W.N.W. of the city of Bari. Pop. (1961) 57,994 (commune). It dates from the middle ages and the medieval town is clearly distinguishable from the modern. The cathedral of S. Corrado, a national monument, is in the Romanesque style and dates from the 13th century. Molfetta is an important fishing port in the lower Adriatic; other industries are boatbuilding and the manufacture of foodstuffs, cement, chains and oil. Fish and vegetables are exported.

**MOLIÈRE** (1622–1673), often called the greatest of French writers, was born and died in the heart of Paris. The registers of St. Eustache show him to have been baptized as JEAN BAPTISTE POQUELIN on Jan. 15, 1622. His mother died when he was ten; his father, one of the appointed furnishers of the royal household, gave him a good education at the College de Clermont (the school which, as the Lycée Louis le Grand, was to train so many brilliant Frenchmen, including Voltaire) and clearly intended him to take over his royal appointment, but this the young man renounced in Jan. 1643, determined to break with tradition and seek a living on the stage. Within six months we have his signature to an act of association (June 30, 1643) with nine like-minded persons to produce and play comedy with a view to maintaining their company under the name of the Illustre Théâtre. His stage name, Molière, is first found in a document dated June 28, 1644. He was to give himself entirely to the theatre for 30 years and to die exhausted at the age of 51.

According to Tallemant des Réaux it was a successful actress, Madeleine Béjart, who persuaded Molière to take to the theatre, but her acting could not save the young company. Documents of 1645 show Molière twice in prison for debts on the building and properties. Existence in Paris with two well-established theatres already seemed financially impossible, so from the end of 1645, for the next 13 years, Molière and his friends sought to gain a living in the provinces. The Illustre Théâtre seems to have been soon dissolved, its survivors associating themselves with a certain Charles Dufresne, under the patronage of the 2nd duc d'Epernon (Bernard de La Valette) and for a time, until his conversion to austere piety, of the prince de Conti (Armand de Bourbon). No history of these years is possible; municipal registers and church records show the company emerging here and there. A letter from the intendant of Languedoc to the consuls of Albi in 1647 asks that they be paid dues and expenses. They were in Lyons intermittently from the end of 1652 to the summer of 1655 (when the poet Charles d'Assoucy comments on their good living and generosity) and again in 1657; they were at Montpellier in 1654 and 1655 and at Béziers in 1656. Clearly they had their ups as well as downs. The unchronicled years are of crucial importance to Molière's career, forming a rigorous apprenticeship to his later work as actor-manager, teaching him how to deal with colleagues, authors, audiences and authorities. His rapid success afterward in Paris, in the face of distinctly adverse conditions, is inexplicable without these years of training. To these years belong Molière's first two known plays: *L'Étourdi, ou le Contretemps*, performed at Lyons in 1655, and *Le Dépit amoureux*, performed at Béziers in 1656.

The turning point in his career was probably the afternoon of Oct. 24, 1658, when, in the guardroom of the Louvre on an improvised stage, the company acted Corneille's *Nicomède* before the king, Louis XIV, and followed it with what Molière described as one of those little entertainments which had won him some reputation and which he used to offer to provincial audiences. This was *Le Docteur amoureux*, which apparently brought the house down and secured the company's adoption by Monsieur (the king's brother Philippe, later duc d'Orléans). From this date onward the known facts about Molière almost exclusively concern his activity as actor-manager and author. Whereas earlier writers used to speculate at length on the details of Molière's personal life, all that need be given here is a brief summary of the principal events as an introduction to his work.

For two years after his success of Oct. 1658, Molière's company had the use of a hall in the Petit-Bourbon, a great house adjacent to the Louvre. There took place the first performances of *Les Précieuses ridicules* (Nov. 18, 1659) and of *Sganarelle, ou le Cocu imaginaire* (May 28, 1660). *Les Précieuses ridicules* (see below) was repeated many times in 1660. In the same year he took out a privilege to print the texts of his plays and resumed again his right to his father's appointment as furnisher to the king. In Jan. 1661, on the demolition of the Petit-Bourbon, the company moved to a hall in the Palais-Royal, where all Molière's future plays were to be staged except those which he was commanded to produce for royal galas or private patrons. His one tragedy, *Dom Garcie de Navarre, ou le prince jaloux* (Feb. 4, 1661), was a failure, but *L'École des maris* (June 24) was another success. *Les Fâcheux* (Aug. 17) was composed for an entertainment at Vaux.

On Feb. 20, 1662, Molière married Armande Béjart. It is not certain whether she was Madeleine's daughter, as contemporaries thought, or her sister, as the documents state. She bore Molière three children, but only one of them, his daughter, survived to maturity. Their married life was not happy, and the flirtations of Armande were made the subject of hostile pamphlets.

*L'École des femmes* (*see* below), first staged on Dec. 26, 1662, ran till Aug. 12, 1663, but caused considerable outcry, to which Molière replied in two more comedies, *La Critique de l'École de femmes* (June 1) and *L'Impromptu de Versailles* (at Versailles in October). In 1664 he produced *Le Mariage forcé* in the Louvre (Jan. 29) and, for a gala at Versailles, not only *La Princesse d'Élide* (May 8) but also the first version of *Tartufe* (May 12; *see* below). This great comedy provoked more opposition than any of his other works, and his next play, *Dom Juan, ou le festin de Pierre* (Feb. 15, 1665; *see* below), caused another scandal. In the following August, however, despite the attacks on Molière the king himself took over from Monsieur the patronage of the company, which was henceforth known as *la troupe du Roi*. On Sept. 13, 1665, at Versailles appeared *L'Amour médecin*, in which Molière began that satirizing of the medical profession which he was to make more pointed as ill-health from 1666 onward brought him more experience of doctors.

The year 1666 saw *Le Misanthrope* (June 4; *see* below), *Le Médecin malgré lui* (Aug. 6) and *Mélicerte* (Dec. 2). The last-named was composed for a series of winter entertainments at St. Germain, to which Molière subsequently added *La Pastorale comique* (Jan. 5, 1667) and *Le Sicilien, ou l'amour peintre* (Feb. 10). In the following months Molière was seriously ill, but he returned to the theatre in June. On Aug. 5, 1667, *Tartufe*, with the subtitle *L'Imposteur*, was shown publicly for the first time in Paris, but on the next day it was banned by order of the *président* Guillaume de Lamoignon. The archbishop of Paris, Hardouin de Péréfixe, reinforced this ban with ecclesiastical censure. This was the occasion of the defense of the play in a famous pamphlet *Lettre sur l'Imposteur*. In 1668, after producing *Amphitryon* at the Palais-Royal (Jan. 13) and *George Dandin* at Versailles (July 15), Molière on Sept. 9 at the Palais-Royal gave the first performance of *L'Avare* (*see* below). Early next year authorization was at last given for public performances of *Tartufe*, which began on Feb. 5, 1669. *Monsieur de Pourceaugnac* (Oct. 6, 1669) was written for the king's stay at Chambord, and *Les Amants magnifiques* (Feb. 4, 1670) for St. Germain. *Le Bourgeois gentilhomme* (*see* below) was first performed at Chambord on Oct. 14, 1670, and *Psyché*, a most spectacular production, in the Tuileries on Jan. 17, 1671 (it was subsequently transferred to the Palais-Royal). This was followed by *Les Fourberies de Scapin* at the Palais-Royal (May 24) and *La Comtesse d'Escarbagnas* (at St. Germain, Dec. 2, 1671). *Les Femmes savantes* (*see* below) was presented at the Palais-Royal on March 11, 1672.

In Aug. 1672 Molière fell ill again. On Feb. 10, 1673, he appeared in the first performance of his last play, *Le Malade imaginaire* (*see* below), at the Palais-Royal. During the fourth performance of it on Feb. 17, 1673, he was taken gravely ill on the stage. Carried back to his house in the rue de Richelieu, he died there in the same night. As he had not been given the sacraments or the opportunity of formally renouncing the actor's profession, he was buried without ceremony and after sunset on Feb. 21.

### THE MAN OF THE THEATRE

This great writer was not in the usual sense an author. He wrote little that could be then called literature or that was meant for publication: some poems, one in praise of his friend Pierre Mignard's decoration of the Val de Grâce, and a translation of Lucretius, unfinished and unpublished. His comedies were written for performance and were only published after the text of two of them had been pirated by Jean Ribou. Molière took out a "privilege" to publish in 1660 but made no use of it till 1662. He left seven of his plays unpublished, never issued any collected edition, never as far as is known read proofs or bothered with his text. It was as an actor that he wrote, for acting purposes. Comedies, in his view, were made only to be acted. This fact was forgotten in the 19th century, and it is to 20th-century actors such as Louis Jouvet, Charles Dullin and Jean Louis Barrault that we owe a new sense of his dramatic genius.

Competition, the fight for existence, was the keynote of Molière's whole career. His company had to share the hall of the Palais-Royal with the Italians. To keep his actors and his audiences, in face of the established theatres at the Hôtel de Bourgogne and the Marais, was an unremitting struggle. His fame was in the first place due to his winning the contest, as it were, singlehanded. He held his company together by his personality; he made up for lack of authors by writing more plays himself. The asperity of the struggle has been uncovered only by patient research. He could never sit back and enjoy leisure; his works could not be slowly elaborated or rewritten. He could be sure neither of his actors nor of his authors—Racine, whose first play, *La Thébaïde*, he had put on in 1664, transferred *Alexandre* in 1665 to the Hôtel de Bourgogne while Molière's company was actually performing it. He was constantly in trouble with the authorities: even *Les Précieuses ridicules* had to be taken off for a fortnight three weeks after the first production; *Dom Juan* ran for 15 performances only; *Tartufe* was held back for years. His life had the luck of the theatre: everything was uncertain, experimental. Certain plays brought him enormous successes, *L'École des femmes* in 1662, *Tartufe* at long last in 1669. Recruits to the company made up for desertions. He enjoyed royal favour less than has been said, and it was capricious. The pension promised to the company by Monsieur in 1658 was never paid; the court supported his lighter plays more than his greater works. It seems that he had practically lost the royal favour to Lully in his last years. The receipts of his company show great fluctuation. As they fell, we find him writing more. René Bray (see *Bibliography*) calculates that he wrote 31 of the 95 plays put on the stage by his players in the 14 years 1660–73. To meet the situation caused by his own illness, the seven weeks of mourning for Anne of Austria and the proscription of *Tartufe* and *Dom Juan*, he wrote five plays within the season of 1666–67, of which only one, *Le Médecin malgré lui*, was financially successful.

His own acting was at once his disappointment and his glory. He aspired to be a tragic actor and was not considered such by his contemporaries, partly because audiences then favoured the pompous style of strutting and chanting and roaring. He had rather the build, the elasticity, the india-rubber face of the born comedian. Though neither a great talker nor what is known as a merry man, he imitated gesture and speech irresistibly. He had the tireless energy of the actor, always ready to make a scene out of any incident, putting himself on the stage: he gave Harpagon his own cough, Alceste his own moods, and made a play out of his own green room. The characters of his greatest plays are very like the members of his company. It was quite in character that he died playing the part of the sick man that he actually was.

It cannot be that his acting genius has had no influence on his writing, since he wrote what he could most naturally act. He gave himself choleric parts, servants' parts, a henpecked husband, a foolish bourgeois, a superstitious old man who cursed "that fellow Molière": the comparison with Charlie Chaplin in our own day recurs constantly. His success, on stage and in writing scenes and composing parts, was due in part to this energy but also to another quality that one can only describe as intensity of dramatic vision. He seems to have been incapable of visualizing a situation without vivifying it, dramatizing it, forcing it to the limit of probability and often recklessly beyond. Here again actors have helped to recover an aspect of his genius that scholars had neglected, his theatrical violence. To think of his plays as arguments for a reasonable view of things is to miss their true vitality. He imagines characters so excited that their language becomes incoherent, their actions absurd. He seems always to have sacrificed plot to vivacity. This is natural if one remembers his medium and gifts. He who could get anything across was satisfied to get a scene across, no matter what rules of writing it defied. To think of him as the cool apostle of reason, like the *raisonneurs* of his plays, is a heresy that dies hard, but careful study of the milieu in which as a craftsman of the theatre Molière worked should make such a heresy impossible. The comedies are not sermons; any doctrine they may contain is incidental and not an attempt to improve or instruct. The ideas discussed do not belong so much to the author as to the public whom they were intended to please. Had we been able to ask their author what he thought of hypocrisy or atheism, he would

have marveled at the question and agreed with Lamoignon that the theatre was not the place to discuss such matters. Despite continued argument to the contrary, there is no documentary evidence that Molière ever tried to get his own views across in his plays, whether on marriage, or on the church, or on hell or on class distinctions. Strictly speaking, we do not know his views on these subjects. All we know is that he worked for the theatre and that he used to the full his gift, unique and amazing, of forcing the maximum of dramatic suggestion out of any scene or conversation that he imagined. If he has left us a vivid picture and a sympathetic picture of an atheist, that is because of his imagination, not because of his ideas. His picture of the earthy servingman is no less vivid and sympathetic. Scholars who have tried to make his plays prove things and convey lessons have made little sense of his work and have been blind to its inherent fantasy and imaginative power.

## NINE GREAT PLAYS

If (as would seem to be the case) the power of Molière's writing lies in its creative vigour of language and suggestion, the usual divisions of his work into comedy of manners, comedy of character and farce are not helpful. There is again no evidence that he set out in any given instance to write a certain sort of play. The evidence is rather that an occasion presented itself for him to animate figures around a skeleton theme. The work that emerged was always actable (it was meant to be); in fact it frequently left an indelible impression, one that audiences wished to see over and over again. This impression is given by the vigour and life of the words, not by the story or plot of the play. To recount Molière's plots is therefore to leave out the essentials of his plays. For purposes of information, however, it may be well to give some account of the content of his main plays.

**Les Précieuses ridicules (1659).**—This play, the first that Molière wrote for a Parisian audience, is in many ways typical of all that were to follow. Its origin has been shown to be polemic, within the coterie of the finance minister Nicolas Fouquet, of the most violent kind. Its satire was so personal that it had to be taken off for a fortnight; what we now read or see is a revised and generalized version. It is built on the theme of two provincial girls anxious at all costs to be in the fashion of Paris as established by the *Précieuses*, and their exposure by valets masquerading as their masters. The play does not obey the canons and rules laid down by contemporary theorists of drama. It has no discernible exposition or denouement; the unities do not arise. The entertainment is provided in a succession of scenes that enforce the comic contrast between desire for elegance without common sense on the one hand and plain downright presence of mind without any real culture on the other. The girls can risk fatuities like "voiturez-nous ici les commodités de la conversation" ("carriage us here the conveniences of conversation") while the valets grossly offer to show their wounds and are actually undressed on stage by their masters. The fun seems too obvious for comment, yet by the end we know in detail what an intelligent observer might have seen in the *Précieuses:* the affectation, in the name of culture and distinction, of thinking material things vulgar, of regarding marriage as something altogether shocking ("une chose tout à fait choquante") coupled with an entire lack of discernment that failed to distinguish between taste and valets' fooling.

**L'École des femmes (1662).**—Some good judges have considered *L'École des femmes* to be Molière's masterpiece, in the sense that he never came nearer to pure comedy. Based on *La Précaution inutile* (1657), Paul Scarron's adaptation of a Spanish story, the comedy shows how a man may be so exasperated by feminine coquetterie that he decides to marry a fool. Arnolphe is a pedant, who has thought out a complete scheme and "cooked up" a girl in a convent from the age of four, so that she shall be entirely untrained in the ways of the modern world. The gradual portrayal in Agnès of an awakening temperament, all the stronger for its naïveté and limitations, is one of the marvels of modern comedy. The crowning fantasy is to imagine the pedant falling in love himself, he who had dismissed "all that" as beneath him, and with the person whom he had done his best to make unlovable. He has to eat his words, and his elephantine gropings toward the language of love are his punishment and the spectators' delight. As we shall see, this play aroused much hostility, partly perhaps because men felt that here was an ebullience of comic power for which nothing could expect to be sacrosanct.

**Tartuffe (1664–69).**—When in Molière's own street a hypocrite seduced his landlady, Molière's friends must have felt uneasy about his notion of making a play on that theme, for fear of what the church and the authorities would say. Yet he did make just such a play, and it brought him more trouble and more notoriety than any other. *Tartuffe* was played (in a three-act version now lost) before the king at a Versailles gala in 1664. It seems reasonable to think that it portrayed a pious crook, Tartuffe, so firmly established in a bourgeois household that he can make the master, Orgon, promise him his daughter's hand and disinherit his son in Tartuffe's favour. This went near the bone, for lay directors of conscience were in fact placed in families to reprove and reform manners. The play showed the "holy" man's sensuality tempting him too far, into making love to his employer's wife. Caught in the act, he recovers by masterly self-reproach. Orgon, taken in completely by appearances, not only pardons him but urges him to see his wife as much as possible "pour faire enrager le monde" ("to infuriate people"). Molière must have seen a lot in this theme, for in the final version, as publicly performed in 1669, the play is lengthened to five acts and contains two seduction scenes, and the interest is transferred from the gullible bourgeois to the paradox in Tartuffe himself, outwardly an inhuman ascetic but actually a very human sensualist and glutton. It is difficult to think of a theme more likely to give offense in 17th-century Paris, yet the tenacity with which Molière stuck to his design is matched by the brilliance of dramatic execution. The play seems to exploit another case of the dichotomy discovered in *L'École des femmes*. Arnolphe came to grief because he trusted in wit and forgot instinct. Tartuffe seems to have been imagined on similar lines. It is a recurrent theme, for which Molière seemed to delight to invent new cases.

**Dom Juan, ou le festin de Pierre (1665).**—This play, meant to be a quick money raiser, was a costly failure that had only 15 performances before it was mysteriously removed and never either repeated or published by Molière. It is a priceless example of his art. Dom Juan thinks himself free from all obligation and believes neither in God nor hell nor doctors, nor in the sacredness of promises, yet as an aristocrat assumes that others will keep their obligations to him who acknowledges no obligation. His servant Sganarelle is his opposite in every point, earthy where he is lofty, timorous where he is scornful, superstitious where he is skeptical. They form the perfect French counterpart to Don Quixote and Sancho, yet the play had no success until modern actors showed its power.

**Le Misanthrope (1666).**—By contrast *Le Misanthrope* almost from the beginning was treated as a masterpiece by discerning critics, if not by the general public. It is a drawing-room comedy, constructed from the elements of Molière's own company, with himself in the role of Alceste, the hasty, well-meaning but blind critic of everybody else, the more irritating because he claims the highest motives, and Molière's wife as the flirt Célimène, who is equal to every occasion. The technique of structure is as simple as it is profound and poetic. After railing against humanity, Alceste has to face a fop and give an "honest" opinion on his poem; he is too good-natured to do so at first, then really speaks his mind, with disastrous results. He thinks he has a cast-iron case against Célimène but crumples up at once when it does not go his way. The marvel is that this brilliant pathological sketch of a doctrinaire is so appealing and his increasing moodiness so entertaining. He is always ready to see the mote in another's eye, regardless of the beam in his own, as ignorant of his real nature as Arnolphe, Tartuffe or Dom Juan.

**L'Avare (1668).**—Sooner or later it was inevitable that Molière would attempt a modern rendering of the ancient comic figure of the miser. *L'Avare* is in prose that reads as if the author had wished to turn it into verse; the stock situations are all renewed, and gradually a picture emerges of a man rendered inhuman by love of money. Harpagon's mania is imagined to the point of

cruelty, pathology and insanity, all in breath-taking scenes of great dramatic force. For those who think comedy must cause laughter the play is too stark. Goethe started a bad fashion by calling it tragic. Yet it would seem to be imagined in much the same way as *L'École des femmes* and the other plays often regarded as greater, involving as it does (in differing forms, of course) a basic separation between the forces of mind and intention, devoted to cruel and inhuman ends, and the underlying instincts and human nature, which is not so homogeneous nor so much a servant of the mind as the subject would have it be. In his distress Harpagon becomes human once more, but a pitiful specimen, quite different from what he thought himself to be. There is laughter in this comedy, but it is incidental; the basic comic suggestion is rather absurdity, incongruity, paradox.

**Le Bourgeois gentilhomme (1670).**—That the master's gaiety or imaginative powers were not yet exhausted is proved by *Le Bourgeois gentilhomme*, an apparent exposure of the contemporary desire of the *bourgeoisie* to compete in magnificence with the great nobility, yet perhaps the least dated of all the comedies. The imaginative power is shown in the fact that the comic figure who might have turned out an unpleasant sycophant and climber is in fact delightful, good-natured, fatuous yet naïve and genuine. His nature (which again he despises) gives us more pleasure than his follies which he thinks to be sensible. Molière seems to return here to the vein of comedy that he had exploited in *Les Précieuses ridicules* and in the farces, of imagining fatuity, not only in the bourgeois but in the masters, and pitting it against common sense in the wife and servant.

**Les Femmes savantes (1672).**—As if he recognized the value of such presentation, Molière renewed it 18 months later with *Les Femmes savantes*, which in lesser hands would have been, as some have thought it, a satire on bluestockings, but which becomes the most refreshing comedy with every appearance of the main character, a bourgeois more sensible than his wife but less forceful. The contrast is so delightful that we forget the less pleasant parts of the play and the fact that Trissotin is a cruel caricature of a respected living contemporary, the abbé Charles Cotin.

**Le Malade imaginaire (1673).**—Molière's last play is about a hypochondriac who fears death and doctors. As the fourth performance of it caused his hemorrhage and death, the irony of events has masked or made readers reluctant to probe the irony of the choice of subject. The power of suggestion is still present, in the author's delineation of servitude to jargon and professionalism, in his imagination of fatuity in young Diafoirus (a would-be doctor with some learning but no sense) and in the old but ever fresh opposition of youth and sense (Angélique and Béralde) to superstition and greed and charlatanry (Argan, Béline, Purgon).

## THE ESSENCE OF THE COMEDY

Few great authors can in their lifetime have given so much pleasure to so many people (that is, before the days of cheap editions) as did Molière. This consideration enables us to see in true perspective the hostility that his plays aroused, not only from professional rivals but from public authorities. The writer now acknowledged to be the greatest classical author of France was in his own day decried as impious and unhealthy. The printed attacks on him are almost all without merit; the plays put on the stage against him enjoyed favour only because of the play they were attacking. *Les Précieuses ridicules* provoked *Les Véritables Précieuses* of Antoine Baudeau de Somaize, *Sganarelle* provoked *La Cocue imaginaire* of François Donneau, and *L'École des femmes* raised such a chorus of discussion that Molière joined in with a dramatic reply in *La Critique de l'École des Femmes* and some months later with *L'Impromptu de Versailles*. Both these playlets of his make excellent points, discussing how much should be read into plays, praising the taste of the court and of the pit and breaking a lance for the new realism that demanded recognizable human types in plays rather than the heroic gallant figures of a previous generation. Dorante, in scene 6 of *La Critique*, states that "vous n'avez rien fait, si vous n'y faites reconnaître les gens de votre siècle . . . c'est une étrange entreprise que celle de faire rire les honnêtes gens" ("you haven't achieved anything in comedy unless you give recognizable portraits of contemporary types . . . making decent people laugh is a strange business"); and later in the same scene he makes his famous statement about the rules which some were anxious to impose on all writers for the stage: "Je voudrais bien savoir si la grande règle de toutes les règles n'est pas de plaire et si une pièce de théâtre qui a attrapé son but n'a pas suivi un bon chemin" ("I wonder if the golden rule is not to give pleasure and if a play that achieves its purpose has not been following the right track"). Now that most documents of the controversy over *L'École des femmes* are long since dead, *La Critique* stands as Molière's nearest approach to an exposition of his guiding principles. *L'Impromptu*, no less original an invention, gives not only a charming picture of the manager with his company but the only direct answer that Molière ever made to personal attacks: "Je leur abandonne de bon coeur mes ouvrages, ma figure, mes gestes, mes paroles, mon ton de voix et ma façon de réciter . . . Mais . . . ils me doivent faire la grâce de me laisser le reste . . . voilà toute la réponse qu'ils auront de moi" ("I gladly let them do what they like with my works, my appearance, my gestures, my words, my tone of voice and my way of reciting . . . But . . . they should be kind enough to leave me what remains. That is the only answer that they will get from me").

This restraint and lightness of touch now seem more remarkable than the violence of the attack on *L'École des femmes*, but that attack was a slight thing compared to the storm raised by *Tartufe* and *Dom Juan*. The official condemnations of *Tartufe* in 1665 and the even more savage pamphlets of Pierre Roullé, curé of St. Barthélemy, and B. A. sieur de Rochemont (probably a pseudonym) drew from the poet valuable statements concerning his art. On *Dom Juan* he made no public reply since it was never officially condemned. The documents in defense of *Tartufe* are two *placets* to the king, the preface to the first edition of the play in 1669 (all published under Molière's own name) and the famous *Lettre sur l'Imposteur* of 1667. The *placets* and the preface are aesthetically disappointing, since Molière was forced to fight on the ground chosen by his opponents and to admit that comedy must be didactic. There is no other evidence that Molière thought this, so it is not unfair to assume that he used the argument only when forced. The *Lettre* is much more important. It provides in a few pregnant lines the aesthetic basis, not only of *Tartufe* but of Molière's revolutionary conception of comedy:

> Le ridicule est la forme extérieure et sensible que la providence de la nature a attachée à tout ce qui est déraisonnable, pour nous en apercevoir et pour nous obliger à la fuir. Pour connaître ce ridicule il faut connaître la raison dont il signifie le défaut et voir en quoi elle consiste . . . la disconvenance est l'essence du ridicule . . . il s'ensuit que tout mensonge, déguisement, fourberie, dissimulation, toute apparence différente du fond, enfin toute contrariété entre actions qui procedent d'un même principe, est essentiellement ridicule. ("The ridiculous is the outward and visible form that nature's providence has fixed to all that is contrary to reason, in order to draw our attention to it and to make us avoid it. To appreciate it, we must appreciate that reasonable quality of which it suggests the lack and perceive what constitutes that quality . . . the essence of the ridiculous is incongruity . . . thence it follows that all lying, disguising, cheating, dissimulation, any outward show different from the underlying reality, in short any contradiction between actions arising from the same principle, is essentially ridiculous")

Here surely is the insight which enabled Molière to create something entirely new in comedy. Didactic comedy, satiric comedy, farce, all these were known before his time and none of them are his invention. But the comedy that is only incidentally funny and essentially rests on a constant double vision, of the right and the wrong together, of the normal and the abnormal, of the true and the specious, of the intelligent and the pedantic, this form of the comic is his invention and his glory.

Comedy depends, in Mme de Staël's view, on constant intrusion of the physical into the realm of intellect. Bergson preferred to describe it as the intrusion of the mechanical into the domain of the spontaneous. The mixing of registers, so to speak, which is suggested by both these definitions, is a constant feature of Molière's work that does not emerge in such thumbnail accounts of the chief plays as given above. The wit, the insight, the fun emerge as frequently in the light plays as in the more serious (Diderot

reminds us that a one-act farce is as complex a product of the imagination as *Le Misanthrope*). Characters are made to play a part, then forget it, speak out of turn, overplay their role, so that in all cases the spectator has the delicious suggestion of two registers mixed. Beaten into acting as a doctor, Sganarelle in *Le Médecin malgré lui* not only invents the right sort of jargon, he enjoys it and, to say something, utters inanities about Hippocrates. Overjoyed to find a patient ignorant of Latin so that he can utter further nonsense, he finally comes up to his famous howler of putting the heart on the right instead of the left. Interrupted by a mild protest, he has to keep up his role of scholar with the immortal "Nous avons changé tout cela." Harpagon in *L'Avare*, describing his miserable condition without his money is pathetic: "Mon esprit est trouble et j'ignore où je suis qui je suis et ce que je fais . . . c'en est fait, je n'en puis plus, je me meurs, je suis mort, je suis enterré" ("My mind is disturbed and I don't know where I am, who I am, what I'm doing . . . it's all over, I can stand no more, I'm dying, I'm dead, I'm buried"). His very violence has carried him beyond the rational into the absurd. This is not an accident but the sign of a powerful imagination on the part of the writer who seems untiring in creating cases of this kind. In the same part of the same play, an even more powerfully poetic suggestion comes through Harpagon's incoherence: "Je veux aller quérir la justice et faire donner la question à toute ma maison . . . si l'on ne me fait retrouver mon argent, je demanderai justice de la justice" ("I want to call the law in and have my whole household put to torture . . . if they don't restore my money, I will have the law on the law"). Does Alceste do any more than this in complaining "J'ai pour moi la justice et je perds mon procès" ("I have justice on my side and I lose my case")? What is here imagined? Surely the tendency to confuse social institutions with moral qualities, to think that if we have courts of justice it is scandalous that complete justice is not in our case given.

This insight into human behaviour so French and so inaccessible to others is near the centre of Molière's appeal to his own nation. When Voltaire described him as "le peintre de la France" he was not referring to realism but to French attitudes for which Molière has imagined an immense variety of incarnations. This may be what gives the French an almost "proprietary" interest in Molière: they appear to regard him as "their" author in a curiously possessive way and to feel at home with aspects of his work that others may tend to overlook. Three of these may best close this survey.

First of all is its formality. Molière's public were delighted by the realism and naturalness of his work precisely because they did not expect these things in literature as we do. Drama for them was formal and as far removed from ordinary speech as possible. Much of his work is in fact in verse. Apart from his acting and the provoking of laughter, his public wished to be "charmed" by spectacle, by a fusion of light and colour and movement in which music and dance were as important as speech. Modern productions that omit the *intermèdes* and ballets are far from the original effect. A similar sense of form is in all the comedies in the opposition of characters, the arrangement of scenes and speeches, the comic repartee carried to its conclusion in defiance of realism.

Psychology is now no longer regarded as a governing feature of Molière's work. To speak of him as having created comedy of character, wherein forms of social mania are studied, is an overemphasis of academic criticism. Is the psychology, even in the greater plays, so deep and sound? The French prefer to see them as creations of fantasy, an imaginative and poetic quality that vivifies ideas and attitudes only to drop them and pass on when a point has been taken. *Le Misanthrope* is not usually in France held to be a study of misanthropy or even a French equivalent of *Hamlet* but a subtly arranged chorus, so to speak, of voices and attitudes that illumine the attitude of the individual in society. The play charms by its successive evocation of this single and central theme. To speak your mind is easy when you are annoyed or detached or disapproving or when society has hurt you, and to be frank may be honourable and idealistic, it may equally well be egoistic and self-seeking and rude and spiteful. All centres round a concept; our inability to see ourselves or, as the charming Célimène puts it, "ce grand aveuglement où chacun est de soi." It is in this fantasy playing on the mystery of the self-centred character that Molière is, in the eyes of his own people, unsurpassed.

A third quality admired in France is a kind of intellectual penetration that distinguishes parts of a man from the whole man. Montaigne, to whose thought Molière owed much, has separated "acquired qualities," learning or politeness or professional competence, and "natural qualities," such as self-interest, humanity, animality, what we would often just call "human nature." Conversations in Molière seem designed as crucibles in which the shock of characters and interests makes social veneer peel off. How many dialogues in his plays start with politeness and end with open insults?

The final achievement of Molière's imagination may well be the double vision to which his comic genius led him—the simultaneous presentation of a quality and its opposite, the norm and the aberration, the scandal and the reaction, ingenuity and nature, scheme and reality, principle and practice. Dandin, in *George Dandin* (1668), may well be one of his greatest creations. If taken seriously, then he is a pathetic figure out of place in comedy. But there is never time to take him seriously and indeed for the French *he*, as something in flesh and blood, does not exist, as they see only his emphases, his judgements, his terribly human and typical blunders.

For many people a man is not comic who is so outwitted by a faithless wife as to make him want to drown himself. The French see not a man but a comic attitude, that of expecting that the world will help the honest, and of finding that it inexplicably hits him (or rather us) again and again. This is so, yet it is a scandal to our sense of order. "J'enrage d'avoir tort lorsque j'ai raison" ("It infuriates me to be wrong when I'm right"). The subject is trivial, the intellectual suggestiveness is limitless. A way has been found for comedy to embrace everything, things in the mind and outside it, thanks to the double vision that keeps the contrasting terms both present to the charmed spectator. Things that are not are evoked to illumine things that are. As the hearty Sosie in *Amphitryon* puts it "Cela choque le sens commun. Mais cela ne laisse pas d'être" ("That conflicts with common sense. But it is so, for all that").

BIBLIOGRAPHY.—*Editions:* Collected editions of Molière's works include those by C. Varlet dit Lagrange, 8 vol. (1682); by M. A. Joly, 6 vol. (1734); by E. Despois and P. Mesnard, in the "Grands Ecrivains de France Series," 13 vol. (1873–1900); by R. Bray in the "Belles Lettres Series," 8 vol. (1911–51); by G. Michaut, 11 vol. (1949); by M. Rat, in the "Pléiade Series," 2 vol. (1956); and by R. Jasinski, in the "Garnier Series," 2 vol. (1962). Amongst editions of particular plays those of *L'Avare* by C. Dullin (1948), of *Le Malade imaginaire* by Pierre Valde (1948), of *Les Fourberies de Scapin* by J. Copeau (1951) and of *Tartuffe* by F. Ledoux (1951), all in the Collection Mise-en-Scène, as well as that of *Le Misanthrope* by G. Rudler (1947), deserve special mention.

*Biography.* Earlier literature is superseded by G. Michaut, *La Jeunesse de Molière* (1922), *Les Débuts de Molière à Paris* (1923) and *Les Luttes de Molière* (1925). *See* further J. Palmer, *Molière, His Life and Works* (1931); G. Michaut (ed.), *Molière raconté par ceux qui l'ont vu* (1933); G. Mongrédien, *La Vie privée de Molière* (1950); and R. Bray, *Molière, homme de théâtre* (1954).

**MOLINA, LUIS DE** (1535–1600), Spanish Jesuit theologian who worked out an original theory of the relationship between divine foreknowledge and human free will, was born into the lower nobility of Spain at Cuenca, Castile, in Sept. 1535. He became a Jesuit at Coimbra (1553), studied philosophy and theology there (1554–62) and at Évora (1562–63), taught philosophy at Coimbra (1563–67) and theology at Évora (1568–83), spent his last years

writing and died in Madrid on Oct. 12, 1600. His works include his celebrated *Concordia liberi arbitrii cum gratiae donis* (1588–89), *Commentaria in primam partem divi Thomae* (1592) and *De iure et iustitia*, six volumes (1593–1609).

Molinism has been a bone of contention between Dominicans (as Thomists) and Jesuits for over three centuries. Molina in his *Concordia* aimed at a unified and coherent conception of divine justice and mercy, foreknowledge and providence, predestination and reprobation, efficacious and sufficient grace, and human freedom. His originality lay in a reformulation of traditional views on divine knowledge to stress the component (called *scientia media*) regarding human choices that not only could but also would occur. The strength of his theory lies in its basic simplicity and coherence, its weakness in the possibility that the shift of attention to hypothetical future choices transposes issues without solving them. *See* MOLINISM.

**MOLINE**, a city of Rock Island county, northwestern Illinois, U.S., just above the upper rapids of the Mississippi river 167 mi W by S of Chicago. The name was derived apparently from the Spanish word *molino*, meaning "mill." Swedish immigrants played an important part in the settlement of the town, laid out in 1843. John Deere, inventor of an improved steel plow, settled in Moline in 1847 and established a small shop there. With the advantages of a broad agricultural hinterland and exceptional transportation facilities, Moline, sometimes called "The Plow City," was by 1890 a centre of plow production. Farm implement manufacturing, a major industry, is a part of a large industrial complex whose products include heating and ventilating equipment, tools, clothing and furniture. Pop. (1960) 42,705; Davenport–Rock Island–Moline standard metropolitan statistical area (Scott county in Iowa and Rock Island and Henry counties in Illinois) 319,375. For comparative population figures *see* table in ILLINOIS: *Population*. (D. L. A.)

**MOLINET, JEAN** (1435–1507), French poet and chronicler, a leading figure among the Burgundian *rhétoriqueurs* (*see* FRENCH LITERATURE: *15th-Century Prose*), was born at Desvres in the Pas-de-Calais. After studies in Paris he entered (*c.* 1464) the service of Charles the Bold, duke of Burgundy, becoming secretary to Georges Chastellain, chronicler and court poet; on the latter's death he succeeded to this appointment, continuing to hold it from Mary of Burgundy and Philip the Handsome. His duties as chronicler took him far afield to the wars and on the journeys of the court. He died at Valenciennes, Aug. 23, 1507. His writings include a prose version of the *Roman de la Rose*, an *Art de Rhétorique* (1492), mysteries and religious poems, occasional verse and parodies. Molinet was essentially a man of the late middle ages, not of the Renaissance; an incomparable virtuoso with words, he prepared the way for Rabelais.

Dupire, *Étude critique des manuscrits éditions des poésies de Jean Molinet* (1932) and *Jean Molinet, la vie, les oeuvres* (1932). (H. G. WH.)

**MOLINISM**, a Roman Catholic theological system which endeavours, by avoiding Pelagianism and the extremes of Augustinianism, to explain the action of divine grace on the human will. It takes its name from Luis de Molina (*q.v.*), whose *Concordia* (1588–89) is primarily concerned with the problem of reconciling grace and free will, while seeking to vindicate the doctrine of the Council of Trent that man's will remains free under the action of divine grace. The inherent difficulty of the problem was not lessened by the ambiguity and obscurity of Molina's style. Even before the *Concordia* was published, it was attacked by theologians who had got wind of its contents and wished to prevent its appearance. Indeed when it finally was published it contained an appendix, prepared by Molina, in answer to the principal objections raised against it. Spain soon rang with the controversy it aroused. Its chief, although by no means only, opponents were Thomist theologians of the Dominican order, especially Domingo Bañez.

Rome soon intervened and set up a special congregation to decide the dispute. The congregation during 1598–1607 held 85 sessions, 68 under Clement VIII and 17 under Paul V, listening to the debate between Jesuit and Dominican theologians. In the end it proved impossible to reach a decision. Both opinions were allowed, but the contending theologians were forbidden to censure each other. A somewhat developed Molinism is still taught in Jesuit and other Catholic schools, while the Thomistic system as developed by Bañez also has its adherents. The Jansenists sharply attacked Molinism.

*See* J. Pohle in *Catholic Encyclopedia*, vol. x, pp. 437–441 (1911); F. Stegmüller (ed.), *Geschichte des Molinismus*, vol. i (1935). (E. A. R.)

**MOLINOS, MIGUEL DE** (1628–1696), Spanish priest, proponent of an extreme Quietism, was born at Muniesa, Aragon, on June 29, 1628. He studied theology at the Jesuit Colegio de San Pablo, Valencia, where he was ordained priest in 1652. Sent to Rome in 1663, he soon became one of the city's most esteemed spiritual directors. There in 1675 he published his *Spiritual Guide*, a small handbook of the contemplative life that was an immediate sensation. Some attacked its doctrine and had their efforts put on the *Index Librorum Prohibitorum*, while those who defended it received ecclesiastical advancement. In 1685, when his influence with the people was at its zenith, his favour in ecclesiastical circles most marked and his friend Innocent XI was pope, Molinos was arrested by the papal police, tried and eventually sentenced to life imprisonment for heresy.

The occasion of this sudden reversal of opinion would appear to have been the discovery of his personal immorality, which in turn revealed what had previously remained hidden (perhaps even from himself): the antinomian implications of his doctrine (*see* ANTINOMIANISM). In the "Summation" of his trial he is found defending his own and his followers' sexual aberrations as sinless purifying acts, which, effected by the devil and passively permitted by the truly interior Christian, providentially deepen such a one's quiet repose in God. But as the doctrinal propositions, chiefly from his correspondence, were successively brought forward, his moral sense seems to have been jarred into life once more. He admitted that he had been wrong and offered no further defense. He died in prison at Rome on Dec. 28, 1696.

Ambiguities and misapprehensions long attended the historical evaluation of Molinos, chiefly because in the *Guide*, his only work generally known, doctrines which brought about his condemnation are not to be found; it evidences at most a speculative climate not unfavourable to their origin and development. *See* also QUIETISM.

BIBLIOGRAPHY.—The "Summation" is preserved in the Vallicellian Library, Rome (Ms. P 180). For the 283 propositions considered at the trial, see *Analecta Iuris Pontifici*, vol. x, cols. 570–594 (1868–69) and for the sentence of the Inquisition, vol. vi, cols. 1633–49 (1865); for the condemnation by Innocent XI, J. de Guibert, *Documenta Ecclesiastica*, pp. 269–288 (1931). Other relevant documentation is given in P. Dudon, *Le Quiétiste espagnole Michel Molinos* (1921). *See* also M. Petrocchi, *Il quietismo italiano del Seicento* (1948); R. A. Knox, *Enthusiasm*, pp. 295–318 (1950). An incomplete English version of the *Guide*, edited in 1906 by K. Littleton, is frequently reprinted. Molinos' letters are in the archives of the Holy Office. (E. O'B.)

**MØLLER, POUL MARTIN** (1794–1838), Danish author whose novel of student life heralded a new realistic approach and so marked an important stage in the history of Danish literature, was born near Nakskov on March 21, 1794. After taking a degree in divinity at Copenhagen, he began his literary career by translating Homer. To recover from a broken engagement, he went to China as a chaplain on a Danish ship (1819–21); the literary results were some journals, a number of *Strøtanker* ("Aphorisms"), nostalgic poems about Denmark and Copenhagen (*e.g.*, "Scener i Rosenborg Slotshave") and a witty parody of statistical-topographical descriptions, *Laegdsgaarden i Olsebymagle*. He had already shown gifts as a poet in both humorous and melancholy moods (*e.g.*, "Torbisten og Fluen" and "Aprilvise"), and as a prose-writer in *Eyvind Skaldaspiller*, a saga pastiche. After his return he earned his living by teaching classics, while studying philosophy

Møller first read his most famous work, *En dansk Students Eventyr*, a *novelle* originally planned as a historical novel in the manner of Sir Walter Scott but in its final (though fragmentary) form describing contemporary student life, to the students' union at Copenhagen in 1824. His own character is reflected in the three main characters: Curly Frits, the irresponsible idler; the pedantic Magister; and the antiromantic Bertel. *Blade af Dødens Dagbog* ("Leaves From Death's Diary"), a poetic fragment inspired by Byron, and other sketches such as his witty essay "Quindelighed," demonstrate both his mastery of style and his lack of energy to complete anything. Møller was lecturer in philosophy at Christiana (Oslo) university from 1826 to 1828, when he became professor, and from 1831 he held the chair of philosophy at Copenhagen, where he died on March 13, 1838. Among his students was Søren Kierkegaard (*q.v.*), who much admired him.

The most important of Møller's later works, apart from several philosophical essays, is the poem *Kunstneren mellem Oprørerne*, advocating the artist's freedom from political commitments. Møller's realistic approach to literature in a romantic age may be summed up in his aphorism: "All poetry that does not come from life is a lie."

**MOLLET, GUY** (1905– ), French Socialist who served as premier of France in 1956–57, was born at Flers-del-l'Orne on Dec. 31, 1905. Orphaned during World War I he studied with the help of public grants, joined the Socialist party in 1921 and was teaching English at the Arras *lycée* when, in 1939, he was elected secretary of the Fédération de l'Enseignement, a Socialist teachers' trade union. After serving in the army and in the Resistance during World War II, he was elected mayor of Arras and deputy for Pas-de-Calais in 1945. He was minister of state in Leon Blum's Socialist cabinet (Dec. 1946–Jan. 1947).

As secretary-general of the Socialist party from Sept. 1946, Mollet strengthened the authority of the party machine over the parliamentary group. At first he opposed the party's participation in coalitions without the Communists, but by 1950 he supported it. He was minister of state dealing with the Council of Europe from July 1950 to July 1951. With Pierre Mendès-France he led the left-centre Republican front in the election of Jan. 1956 and was premier from then to May 21, 1957. His government—the longest of the fourth republic—failed to deal effectively with Algeria and was chiefly responsible for the Anglo-French intervention in the Israeli-Egyptian fighting in Oct.–Nov. 1956. He became minister of state under Pierre Pflimlin on May 13, 1958. Having helped to ensure that Gen. Charles de Gaulle's return to power was by constitutional means, he retained his post in De Gaulle's cabinet (June 1958–Jan. 1959). His support for De Gaulle was endorsed by the Socialist party in a stormy congress in Sept. 1958, when the party split. (P. W. C.)

**MOLLIEN, NICOLAS FRANÇOIS,** COMTE (1758–1850), one of Napoleon I's chief advisers on financial matters, was born at Rouen on Feb. 28, 1758. Having worked in the office of the farmers-general of the taxes from 1775, he joined the office controlling their activities in 1781; and it was he who drew up the contract of 1786 whereby their payments to the royal treasury were increased. During the Revolution he was appointed to Evreux to be director of domains for the *département* of Eure in 1791 but was dismissed in 1792 and was imprisoned for five months in 1794. Napoleon Bonaparte, however, made Mollien administrator of the sinking fund in Nov. 1799 and director general of it in July 1801. Under the empire, Mollien was minister of the public treasury from Jan. 1806 to April 1814 and during the Hundred Days in 1815; he reorganized its administration and introduced double-entry bookkeeping. Napoleon, who created him comte in 1808, frequently consulted him but did not always follow his advice. Even so, notwithstanding his own assertions in his *Mémoires*, Mollien did not criticize Napoleon's "continental system" or the sinking fund's purchase of government stocks in order to maintain their price artificially.

After the second Restoration, Mollien retired (July 1815). He refused the offer of the ministry of finance in 1818 but accepted a peerage. Subsequently he sponsored reports on financial questions in the chamber of peers. He published his *Mémoires d'un ministre du trésor public 1780–1815* in 1845 (new ed., 3 vol., 1898). Mollien died in Paris on April 20, 1850.

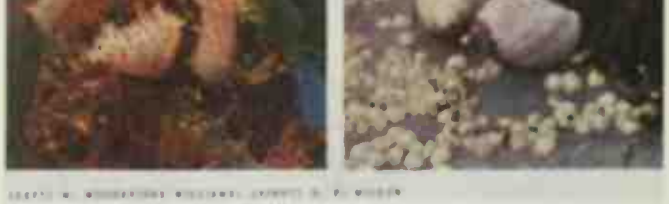
BIBLIOGRAPHY.—N. A. Salvandy, *Mollien* (1851); A. G. P. de Barante, *Études historiques et biographiques* (1857); L. de Lanzac de Laborie, *Paris sous Napoléon*, vol. vi (1910). (C. E. Dr.)

**MOLLUSK,** any member of the invertebrate phylum Mollusca, one of the largest and most important divisions of the animal kingdom. It includes such groups as the gastropods (snails, slugs), pelecypods or bivalves (clams, oysters, mussels), scaphopods (tooth or tusk shells), cephalopods (squids, octopuses, nautiluses) and amphineurans (including chitons). The phylum comprises six classes containing more than 100,000 living species and an even greater number of fossil forms. Mollusks range in size from snails little larger than a grain of sand to giant squids measuring more than 15 m. (60 ft.) from the tip of the extended arms to the end of the tail. Clams range from only a fraction of an ounce to more than 500 lb. (the giant clam, *Tridacna gigas*).

## GENERAL FEATURES

**Importance.**—Mollusks have always been of great interest and importance to man because of their use as food, as tools and utensils by primitive man and as ornaments, money or religious emblems. They are also important as intermediate hosts of trematode parasites that cause serious diseases in man, his domesticated animals and other vertebrates. Shipworms, which bore into wooden vessels or pilings, and bivalves, which foul the bottoms of ships and buoys, are of great concern to fishermen, shipping companies and navies of the world. Industries that use sea water in the cooling systems of plants are also concerned with mussels and other fouling mollusks; the free-swimming larval forms are carried into the intake tunnel with the circulating water and many settle out on the walls, where they become attached, grow rapidly and soon restrict the flow of water. The European fresh-water clam *Dreissena* may do a great deal of damage in clogging water systems. Millions of dollars have been spent annually to solve the problem of fouling mollusks and to develop and produce effective antifouling paints. Mollusks are important to the oil geologist and paleontologist as index fossils and are one of the organisms most often used in carbon dating. They are an aid to anthropologists in tracing the trade routes of primitive peoples who fed on the animals and used the shells as money. Shells are also of interest to collectors and are an important part of the tourist trade in some seaside areas. (*See* also SHELLS AND SHELL COLLECTING; CURRENCY, PRIMITIVE.)

**Habitat and Distribution.**—Mollusks are an extremely adaptable, hardy group of animals that have radiated into nearly all types of habitats—marine, land and fresh water. They range from the greatest depths of the ocean to the tops of high mountains in the tropics. They are found in deserts and tropical rain forests



GASTROPODA OF WIDELY DIVERGENT FORM AND HABITS. (LEFT) CLOWN SEA SLUGS (TRIOPHA CARPENTERI). THESE BRIGHTLY COLOURED SOFT BODIED NUDIBRANCHS LIVE IN TIDE POOLS AND FEED ON SEAWEED AND OTHER PLANTS. (RIGHT) TWO DOG WHELKS (NUCELLA LAPILLUS), BORDERED ABOVE BY MUSSELS (BIVALVIA) AND BELOW BY ACORN BARNACLES (OF AN ENTIRELY DIFFERENT CLASS, CRUSTACEA) ARE SHOWN COMPLETELY EXPOSED AT LOW TIDE. THESE SNAILS FEED ON BARNACLES, CLAMS AND OTHER SNAILS

and in nearly all fresh-water habitats. Land and fresh-water mollusks are more abundant in areas rich in limestone, the raw material for building their calcareous shells. Of the six classes, the Cephalopoda, with the most highly developed nervous, digestive and reproductive systems, are restricted to the marine habitat, probably by some factor in their physiology. The Amphineura and Scaphopoda are entirely marine. The Gastropoda are the most versatile; they are equally abundant in the sea, in fresh water and on land, the land forms having evolved a pulmonary cavity that allows them to breath air. The Pelecypoda are restricted to an aquatic habitat by their method of feeding and respiration, but they have been very successful in invading fresh water. Living Monoplacophora are known only from the great depths of the ocean, though the fossil record indicates that at one time they were abundant in the littoral zone.

Some mollusks are truly pelagic, living their entire lives as free-swimming organisms in the sea. The most important of these are the squids and the sea butterflies (slugs). The greatest abundance of marine forms occurs in the littoral zone, usually at or just below the low-tide line, where there is an abundance of food and the animals are not exposed to the air. Bivalves occurring in the intertidal zone are either deep burrowers that can retreat to the bottom of their burrows during low tide or can close their valves tightly to prevent drying while exposed. Snails living in the intertidal zone are usually forms that have an operculum or plug to close the aperture of the shell during exposure.

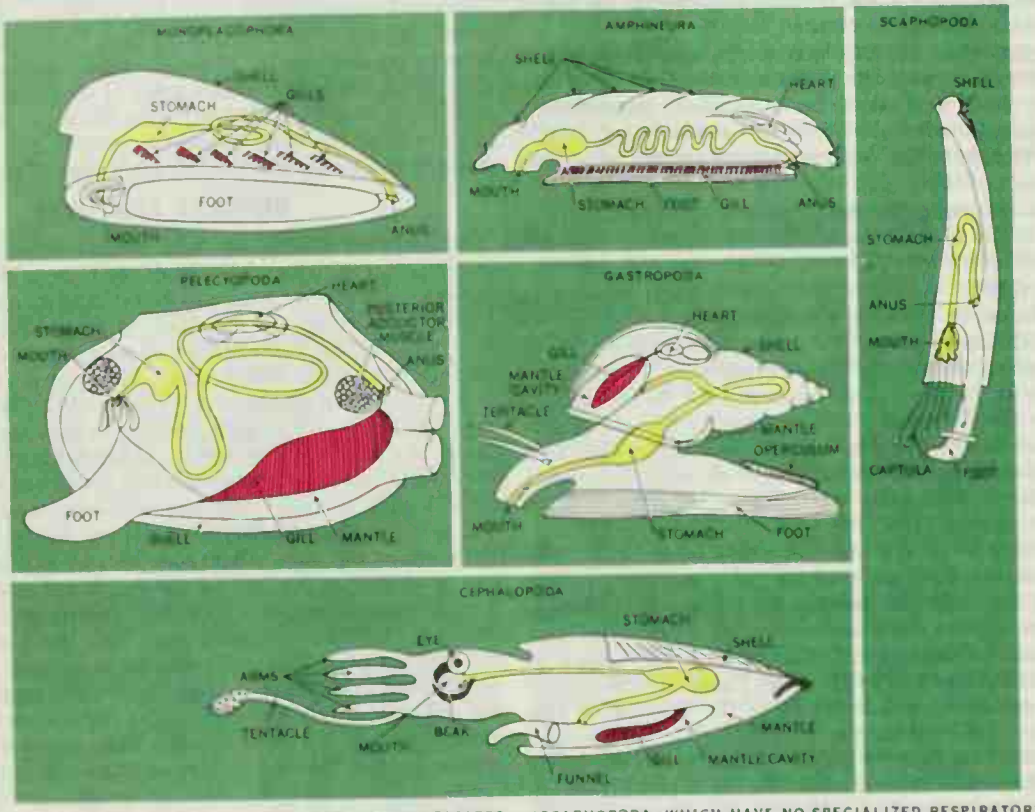


FIG. 1—BODY PLANS OF THE SIX CLASSES OF MOLLUSKS. RED INDICATES THE RESPIRATORY SYSTEM, YELLOW INDICATES THE DIGESTIVE TRACT (SCAPHOPODA, WHICH HAVE NO SPECIALIZED RESPIRATORY SYSTEM, RESPIRE DIRECTLY THROUGH THE FLESHY MANTLE)

MARINE SNAILS (GASTROPODA) THAT APPEAR TO BE TOO LARGE FOR THEIR SHELLS. (LEFT) MOON SNAIL (POLINICES LEWISII) AVERAGES MORE THAN 4 IN. LONG. THE FLESHY FOOT, WHICH "BULLDOZES" THROUGH SAND SEARCHING FOR FOOD, PRACTICALLY ENVELOPES THE GLOBULAR SHELL. (RIGHT) THIS GIANT KEYHOLE LIMPET (MEGATHURA CRENULATA), 7 IN. LONG, HAS A VELVETY BLACK MANTLE WHICH PARTLY COVERS ITS OVAL SHELL. HOLE AT CENTRE OF FULLY FORMED SHELL BEGINS AS A NOTCH IN THE SHELL OF THE IMMATURE LIMPET. AS THE LIMPET AGES, CALCAREOUS SHELL SUBSTANCE IS ADDED IN CONCENTRIC CIRCLES. A LIMPET'S FOOT IS LIKE A LIVING SUCTION CUP BY WHICH THE ANIMAL CAN CLING TENACIOUSLY TO A ROCK OR OTHER SMOOTH SURFACE, REPUTEDLY MORE TIGHTLY THAN ANY OTHER ANIMAL

They remain quiescent during low tide and resume feeding with the return of the sea. Few mollusks are found living in the intertidal zone in high latitudes because of the scouring action of winter ice. Those that are found are usually the young of forms with pelagic larval stages. The free-swimming young are carried in by currents in the early spring and grow throughout the summer, only to be destroyed by the winter ice. A few forms migrate to deep water with the coming of winter. Fresh-water mollusks living in cold temperate and subarctic regions generally burrow into the mud or move out into deeper water at the time of the fall overturn and the arrival of cold weather. They are generally rare or lacking in shallow, rapidly flowing streams in such areas; the turmoil that results from the breakup of the ice in the spring would crush their relatively delicate shells. During periods of drought fresh-water mollusks, both bivalves and gastropods, retreat with the dropping of the water in lakes and streams. In areas of extreme drought, as occur in Africa and Australia, these forms burrow into mud and remain quiescent for long periods until the return of the water. Land shells in high latitudes seek protection by burrowing into the ground with the coming of fall. In desert areas they may secrete themselves under rocks, bury themselves in the ground or fasten themselves to the trunks of trees or rocks by means of a limy mucus that they produce. Some land snails may estivate for several years under such conditions of drought; with the coming of rain they immediately become active, feeding voraciously and breeding.

## STRUCTURE AND FUNCTION

**Basic Body Plan.**—The word "mollusca" or "mollusk" comes from the Latin *molluscus*, meaning "soft," and refers to the soft body of the animal, which is generally enclosed in a protective shell. Until the discovery in the 1950s of *Neopilina galatheae*, a living species of Monoplacophora (*q.v.*), mollusks were also characterized as being unsegmented, but in this rare deep-sea group the organs such as gills, muscles and kidneys (nephridia) are serially arranged in pairs. In all other classes there is only a single pair of each organ and in some groups only one member of each organ is present. All mollusks have a mantle, a thin cape or covering that hangs over the dorsal surface of the body and that secretes the shell. Though a similar organ is also found in the phylum Brachiopoda (the lamp shells), it is quite different in structure from that of the mollusks, and the two lobes of the brachiopod mantle are dorsal and ventral rather than left and right as in the bivalve mollusks. In most mollusks the mantle cavity, the space between the mantle and the visceral mass and foot, contains the gills, but in the land mollusks this space is modified as a pulmonary cavity, which is supplied with numerous blood vessels and functions as a lung. The foot of the mollusks is typically a broad, flat, muscular organ, developed for creeping or plowing. In some forms, however, it is used as a swimming organ, and in the octopus and squid it is modified as tentacles used in securing prey. All appendages of mollusks are soft, lacking internal supporting structures, and they are never segmented.

Mollusks are bilaterally symmetrical, at least in the early stages of development, and in all classes except the gastropods the digestive tract is straight or curved, with the mouth at one end and the anus at the other. The snails are bilaterally symmetrical in the early larval stages, but as the shell develops, the soft parts become strongly displaced so that the mouth and anus are brought close together. Then the portion posterior to the head is twisted in 180° so that the anus comes to lie over the head and generally one of each of the paired organs is lost. The remaining organs are coiled to fit into a spirally coiled shell (*see* SNAIL).

A radula, or rasping, tonguelike organ used in feeding, is present in the forward part of the mouth in all classes except the bivalves. The radula is a long, filelike protrusible chitinous ribbon on which are numerous transverse rows of teeth. By a slight upward sweeping motion of the radula the mollusk can rasp particles of food and carry them into the mouth.

The reproductive system may be relatively simple, as in the chitons, clams and some of the lower gastropods, or highly complicated, as in the land snails and the squids. The fertilized eggs

in all groups except the cephalopods develop into a trochophore; in the scaphopods, pelecypods and gastropods the trochophore is followed by a second larval stage known as the veliger. Both these larval forms may be free swimming or passed within the egg capsule or protective gelatinous mass in which the eggs may be produced. Some land and fresh-water snails produce eggs with a calcareous shell that may be laid in the ground, attached to twigs or rocks, or may be held within the body of the parent until the young are fully developed and emerge as crawling snails. The trochophore is also found in other phyla including the Annelida (segmented worms), but the veliger stage occurs only in the Mollusca.

**Shell and Mantle.**—All mollusks have a mantle and most have a shell in the adult stage, though it may be reduced or internal. The shell and the mantle are so closely associated that in reality they are but a single organ; the mantle produces the shell. The mantle is a thin membranous fold of tissue covering the dorsal surface of the body like a tent, but in some forms, such as the tusk shells and many bivalves, the ventral margins are united to form a tube. Although the mantle secretes the shell, it is not attached to it except at a single point or a few points, depending on the group. In many of the gastropods the mantle is attached only in the region of the columella muscle and can move freely over the inner surface of the shell, allowing the animal to retreat well within for protection. In many bivalves the mantle is attached

to the shell along a line well in from the ventral margin of the shell, extending from the anterior to the posterior adductor muscles. This arrangement allows the clam to retract the edge of the mantle and close the valves.

The outer edge of the mantle is generally muscular, and is typically composed of two or three lobes. The shell is composed of mineral salts, mainly calcium carbonate with traces of calcium phosphate and magnesium carbonate, which are laid down in a framework of conchiolin. The outer surface of the shell is generally covered by periostracum, an organic nitrogenous, chitinlike substance that may vary greatly in thickness and may be smooth, scaly or hairy. It is produced in a groove between the outer and middle lobes of the mantle edge and serves to protect the shell from acids in the environment. The outer lobe of the mantle edge secretes the prismatic layer, which lies beneath the periostracum. It is composed of crystals that are produced generally at right angles to the surface of the shell. The inner laminated layer is secreted by the entire surface of the mantle and is composed of overlapping plates of crystals that parallel the outer surface of the shell. This layer in the lower groups of bivalves and gastropods is usually nacreous, or pearly, and highly iridescent.

The shell increases in size by the addition of prismatic cells to the growing edge, the lip of gastropods or the ventral margin of bivalves. It increases in thickness by the addition of laminated layers to the inner surface of the shell. If the shell is injured in any way or if a foreign object becomes wedged between the mantle and the shell, a mollusk can quickly repair the damage by producing shelly material when the need arises; the breaks are repaired or the foreign object entombed by secretions from the mantle in a short time (*see* PEARL).

In the various groups of mollusks different layers of the shell predominate. In the majority of bivalves the laminated layer is very thick, but in the Pinnidae (the pen shells) the laminated layer is greatly reduced, both in area and thickness, and the shell is composed almost entirely of prismatic material. The large land snails of the genus *Paryphanta* of New Zealand have shells composed almost entirely of periostracum. This is also true of many small North American land and fresh-water snails, particularly those living in areas low in limestone. Some mollusks, such as the cowries and olive shells and those with internal shells, lack the periostracal layer, and in many groups this layer is very thin. Colour may be deposited in all three layers of the shell. Though the periostracum usually ranges from light yellow to blackish-brown, it may be more highly coloured in some land snails. The prismatic layer is colourful in many forms, and it is in this layer that all colour patterns are produced. The inner laminated layer, when coloured, is usually uniform or irregularly mottled. In the lower forms of gastropods and bivalves that have a pearly or nacreous laminated layer, additional iridescent colours result from the physical structure of the shell.

The mantle, in addition to secreting the shell, functions in many other ways. Its inner surface, particularly in bivalves, is lined with cilia that aid in creating water currents important in respiration and feeding. Some marine groups have a mantle outgrowth that functions as a gill, and in land shells the mantle cavity is well supplied with blood vessels and functions as a lung. The muscular inner lobe of the edge of the mantle (also called a velum) often controls the flow of water into the mantle cavity; in scallops it is highly developed and used in swimming. The middle lobe of the mantle edge in bivalves and many gastropods is sensory and is often supplied with fine tentacles and in scallops with bead-like mantle eyes. The mantle forms the siphons of bivalves and, depending on the number of lobes of the mantle involved, the siphons may or may not be covered with periostracum. Many gastropods have a long siphonal canal, an outgrowth of the mantle, which may be held well above the surface on which the snail is crawling.

**Organ Systems.**—Though the shells of the six classes of mol-

FIG. 2.—SHELL STRUCTURE. (LEFT) DIAGRAM OF PARTS OF A BIVALVE MANTLE AND SHELL; (RIGHT) CROSS SECTION OF PRISMATIC LAYER OF A PEN SHELL (PINNA CARNEA) SHOWING CRYSTALS AND CONCHIOLIN NETWORK

lusks vary a great deal, and there appears to be little in common between a chiton and a bivalve or between a gastropod and a squid, the anatomy of the soft parts is more basic, only a general account of which is given here.

*Respiratory and Circulatory Systems.*—Respiration in most marine groups is by means of gills that lie in the mantle cavity or in a groove between the mantle and the foot. The gills, composed of numerous connecting tubular filaments that may be strengthened by chitinous rods, are bathed by fresh, well-oxygenated water brought into the mantle cavity and directed by ciliary currents over the gills. The blood circulates through the tubes of the gill filaments, where the oxygen-carbon dioxide gas exchange takes place. In air-breathing land snails the mantle cavity is lined with a network of blood vessels. In all mollusks the entire body surface also functions in respiration; some, such as the scaphopods, breathe exclusively by this means.

The blood of mollusks is usually colourless, but the pigments hemoglobin and hemocyanin occur in some groups, particularly those adapted to water low in oxygen. The heart is well developed in all groups except the scaphopods and is usually composed of a muscular ventricle and one or two auricles enclosed in a pericardial cavity. The blood is carried from the ventricle of the heart through the anterior and posterior aortas to all parts of the body. It returns from the gills to the auricles. The system, however, is only partially closed, for in all classes except the cephalopods there are open blood sinuses among the organs. The kidneys generally open internally into the pericardial cavity and externally in the mantle cavity.

*Digestive System.*—This system is composed basically of a mouth with a radula in all classes except the bivalves; a short esophagus; a stomach that may be very complicated, particularly in the bivalves and some gastropods; and simple nonmuscular intestine. The liver is the most important digestive gland, but in many groups other digestive glands occur. A crystalline style is found in most bivalves and in a few gastropods, mollusks that feed on phytoplankton or larger aquatic plants. This structure is a gelatinous rod found in the forward part of the intestine or in a special style sac that opens into the stomach. The style extends into the stomach, where it is rotated by means of cilia against a style plate and is slowly worn away, releasing a digestive enzyme, amylase, for the digestion of starch. This slow, constant release of a digestive enzyme is a perfect adaptation for animals that feed constantly on plants. Carnivorous forms generally have less complicated stomachs and shorter intestines. Their digestive glands produce enzymes for the breakdown of proteins. The glands of the more omnivorous feeders may produce a variety of digestive enzymes. Digestion is mainly extracellular, but in some of the lower forms, in which particles of food may also be engulfed by amoeboid cells, digestion takes place intracellularly.

*Nervous System.*—The molluscan nervous system is relatively simple except in the cephalopods (*see* CEPHALOPODA). In the lower forms a nerve ring surrounds the esophagus, and joins the ganglia in the viscera and the foot by means of long nerve commissures. In the higher groups of gastropods the ganglia are all concentrated in the large circumesophageal ring, the nerves emanating from this to all parts of the body. The simple eyes of scallops are sensitive to changes in light intensity; most bivalves have tentacles and filaments on the mantle edge and siphons that are sensitive to touch. Many of the bivalves and gastropods have an additional organ, the osphradium, the function of which is not clearly understood but may be to detect changes in the condition of the water. True eyes are found only in the gastropods and the cephalopods. The eyes of snails are poor, being able to detect little more than changes in light intensity. Those of the squids are highly developed and perhaps as efficient as the eyes of man.

*Reproductive System.*—In the lower forms the sexes are separate and the gonads simple. In some cases eggs and sperm are ejected separately into the water and fertilization takes place externally, where the sperm are carried into the mantle cavity of the female by water currents fertilization is internal. Forms that have such haphazard means of fertilizing their eggs and that provide little or no protection for the developing young produce thousands or even millions of eggs. In the more highly developed marine and fresh-water prosobranch snails a male intromittent organ or penis is developed and the eggs are always fertilized internally. Such groups usually produce the eggs in a protective gelatinous mass, in egg capsules, or retain them within the body of the parent until development is nearly complete; a few groups are ovoviviparous. The pulmonate snails are all hermaphroditic, a single individual having a complete set of both male and female organs. They are capable of self-fertilization but under normal conditions cross-fertilization usually takes place. The system in the higher pulmonate groups is complicated by the addition of many accessory organs. In many gastropods and most cephalopods there is some form of courtship.

## CLASSIFICATION AND RELATIONSHIPS

Mollusks are grouped into six classes on the basis of the type of shell, the number and arrangement of the various organs, the type of foot, the method of feeding and the embryology.

The following taxonomic outline of the phylum Mollusca is one in general use:

Class Monoplacophora
" Amphineura
" Scaphopoda
" Bivalvia or Pelecypoda
" Gastropoda
" Cephalopoda

**Monoplacophora.**—These are bilaterally symmetrical mollusks having a simple cap-shaped shell with the apex central or pointed forward. The head region is poorly defined, lacking eyes and tentacles. The mouth, which has labial palps and a radula, is anterior; the anus is posterior and there is no flexure of the system. The gills, nephridia, muscles and reproductive organs are serially arranged in pairs. The foot is large and flat with a muscular rim. The heart is posterior. The sexes are separate. The developmental stages are unknown but there is probably only a trochophore. Only three living species of this class are known, from the great depths in the eastern Pacific. Fossil forms are known from the Cambrian to the Jurassic. (*See* MONOPLACOPHORA.)

**Amphineura.**—These are elongate, bilaterally symmetrical animals that lack shells or have a shell composed of eight transverse plates. The digestive tract is simple, having an anterior mouth and posterior anus, with no flexure or torsion. The head region is poorly developed, lacking eyes and tentacles, but a well-developed radula is usually present. There is no segmentation of the soft parts. The heart is posterior and dorsal. The sexes are separate. The eggs develop into a trochophore but there is no veliger stage.

CHITONS (*CRYPTOCHITON STELLERI*) AND TWO BLACK ABALONE (*HALIOTIS CRACHERODII*) SHARE ROCK IN INTERTIDAL ZONE. A CHITON MAY SPEND ITS ENTIRE LIFE ON ONE ROCK OR MAY RETURN TO THE SAME ROCK WHEN NOT FORAGING FOR ALGAE. LIKE CHITONS, BLACK ABALONE FEED ON MICROSCOPIC PLANTS (IN CONTRAST TO LARGER FARE TAKEN BY RED OR GREEN ABALONE)

Chitons are entirely marine, ranging from the intertidal zone to deep water; they are known from the Cambrian.

The class is divided into two subclasses (which are sometimes given class rank) on the presence or absence of a shell. The subclass Aplacophora contains wormlike animals in which the foot is rudimentary and the mantle covers most of the animal and is embedded with calcareous spicules. The radula is reduced or lacking. Aplacophorans usually are found in moderate depths. They may be free living, commensal or parasitic. None of this subclass is known as fossil. The second subclass, the Polyplacophora, the chitons or coat-of-mail shells, have the shell consisting of eight transverse plates surrounded by a girdle. The foot is large and muscular, extending nearly the length of the animal. They are known from the Upper Cambrian. (*See* AMPHINEURA.)

**Scaphopoda.**—Commonly known as tusk shells, elephant's tusks or tooth shells, these bilaterally symmetrical mollusks have the shell tubular, open at both ends, the smaller end being posterior. The mantle is united on the ventral margin to form a tube and is fastened to the shell at the posterior end. There is no true head; the mouth is at the end of a snoutlike projection and is surrounded by contractile and prehensile filaments called captacula, which are used for catching food. There are a well-developed radula and jaws. The digestive tract is simple and bow shaped. There are no gills and respiration is carried on over the entire surface of the body. The circulatory system is poorly developed, lacking definite blood vessels and a heart. The foot is variable but is usually pointed or boat-shaped. The sexes are separate. The eggs develop into trochophore and veliger larvae. Tusk shells are entirely marine, ranging from shallow to very deep water, usually living partially buried in the mud, though one species is known to cement itself to bottom detritus. Scaphopods are known from the Ordovician to the Recent period, though they are believed to have existed as early as the Cambrian. (*See* SCAPHOPODA.)

**Bivalvia.**—These mollusks, also known as Lamellibranchia or Pelecypoda, are commonly referred to as bivalves or clams. They are bilaterally symmetrical, having the shell composed of two valves hinged at the dorsal margin and usually held together by a ligament. The foot is usually hatchet-shaped, capable of considerable extension and developed for digging or plowing. The head region is poorly developed, lacking eyes, tentacles and radula, but having labial palps. Respiration is by means of gills and feeding by means of cilia and mucus. The sexes are generally separate; fertilization is external or takes place in the mantle cavity.

The eggs develop into trochophore and veliger larvae. There are marine and fresh-water forms. Restricted to an aquatic habitat by their method of feeding, bivalves may be found from the intertidal zone to great depths. They are abundant as fossils and are known as far back as the Cambrian. (*See* BIVALVE.)

**Gastropoda.**—Commonly known as snails, these are asymmetrical mollusks characterized by having a univalve shell (sometimes greatly reduced or lacking) that may be variously shaped but is usually spirally coiled. In the single case of the family Juliidae the shell is bivalve in the adult. The foot is usually developed as a creeping organ. The head region is well developed, having eyes and tentacles. The mouth has a radula and often jaws. Respiration is by means of gills, a pallial outgrowth or pulmonary cavity. Sexes may be separate or united. Fertilization is internal except in a very few lower forms, and an intromittent organ is present in the male in most species. The eggs develop into trochophore and veliger larvae, which may be free swimming, enclosed within a protective covering or retained within the body of the parent. Gastropods are known as far back as the Cambrian and the fossil record of the marine prosobranchs is very rich. (*See* SNAIL.)

**Cephalopoda.**—This class includes such well-known forms as octopuses, squids and nautiluses, the most highly developed of all invertebrate animals. They are bilaterally symmetrical. The head region is well developed, with the ganglia concentrated in a brain. The eyes are highly developed and efficient sense organs. The mouth is surrounded by tentacles and arms, modifications of the foot, and is provided with powerful beaks or jaws and a strong radula. The mantle in most forms is thick and muscular and surrounds the animal; the funnel in conjunction with the mantle controls the flow of water through the mantle cavity. The propulsive activity of the funnel and the fins are used in swimming. The shell is reduced and internal or lacking in all living forms except *Nautilus*. Respiration is by means of gills. The circulatory system is highly developed, with a complete, closed system in most forms. The sexes are separate and development is direct. There

LAND SNAILS. (LEFT) GARDEN SNAIL (CEPAEA HORTENSIS) WHICH, WHEN THREATENED, USES ITS SHELL FOR PROTECTION BY RETREATING COMPLETELY WITHIN. (RIGHT) GARDEN SLUG (LIMAX), WHICH INSTEAD SPITS MILKY MUCUS INTO THE PATH OF ONCOMING PREDATOR. MOST LAND SNAILS AND SLUGS HAVE WELL-DEVELOPED HEAD REGIONS WITH A PAIR OF RETRACTILE TENTACLES, EACH OF WHICH BEARS AN EYE AT ITS TIP. IF A TENTACLE IS CUT OFF, THE MOLLUSK CAN GROW ANOTHER ONE. FEEDING MAINLY ON VEGETATION AND LEAVING A TRAIL OF MUCUS WHEREVER THEY GO, LAND SNAILS AND SLUGS LIVE IN DIMLY LIGHTED, MOIST PLACES, COMING OUT TO FEED USUALLY AT NIGHT AND ON OVERCAST DAYS

AMERICAN SQUID (LOLIGO PEALEI) FOUND IN SCHOOLS ALONG THE ATLANTIC COAST. THE ELONGATED BODY WITH HORIZONTAL MUSCULAR FINS ENABLES THIS SHELL-LESS MOLLUSK TO SWIM BACKWARD OR FORWARD OR TO TURN SHARPLY AT HIGH SPEEDS. THE TWO LONGER TENTACLES ARE USED FOR GRASPING PREY WHILE THE EIGHT SHORTER ONES TRANSFER FOOD TO THE MOUTH

is no trochophore or veliger stage. Cephalopods are entirely marine; they are found in all seas, from shallow water to profound depths. They are known from the Upper Cambrian. The Nautiloidea reached their greatest abundance in the Ordovician, there being only three living species of this subclass. The subclass Ammonoidea is completely extinct but was abundant in the Jurassic. The fossil record of the subclass Coleoidea is not so rich as that of the other subclasses but they are known from the Upper Mississippian. (*See* CEPHALOPODA.)

**Relationships.**—Mollusks may be related to the brachiopods; they share with them the mantle, the shell and the trochophore larval stage. With the phylum Annelida they are related on the basis of the trochophore larval stage and, with the discovery of *Neopilina*, serial arrangement of paired organs. The relationship of the mollusks to the segmented worms has been recognized for a very long time, and early scientists often classified them in the large general group Vermes (worms).

Many attempts have been made to relate the six classes of mollusks to one another. However, all classes go so far back in the fossil record, and that record is still so incomplete, that it is impossible to do more than theorize. In fact, the anatomy of the soft parts is so important in the classification of mollusks (and the soft parts, of course, are not preserved in fossils) that it may never be possible to answer some of the questions of relationship. It is generally believed that the chitons are closer to the Monoplacophora than to the other classes, but whether they were derived one from the other or from some common stock is not known. The scaphopods show certain characteristics, such as the radula, that relate them to the gastropods, but others, such as the foot and the veliger larval stage, appear closer to the pelecypods. The cephalopods are said to be more closely related to the gastropods than to other mollusks, but the embryology of the cephalopods is so totally different from that of all other classes that it seems difficult to believe there is any close relationship.

Mollusks are known to have existed as far back as the early Cambrian and all six classes were well differentiated by the Upper Cambrian. They have been highly successful and, except for the class Cephalopoda, are today more abundant than at any time in their long history of existence.

(R. D. T.)

**MOLLY MAGUIRES,** a term applied to certain men in the anthracite coal-producing counties of Schuylkill, Luzerne, Carbon and adjacent counties in Pennsylvania, who violated property rights of coal-mine operators and even committed murder during the years 1862 to 1876. In those areas there had been a large immigration of Irish workers. Foreign-born Welsh and Germans were also numerous. There were draft riots during the Civil War, and the area was divided by racial, religious and language barriers, anti-Catholicism and labour struggles. Radicalism born of Chartist, Marxist and former nationalist loyalties vied with trade-union organizational attempts and with the vigorous laissez-faire conduct of mine and railroad operators during times of coal price fluctuations to make the vicinity ripe for violence.

The Irish, a surplus labour force inexperienced in mining, were often embattered by arbitrary wage cuts, company stores, employment discrimination and blacklisting of independent spirits. Many joined the Workingmen's Benevolent association (an early union) in its pioneering efforts to win concessions from the Anthracite Board of Trade, the Mahanoy Valley and Locust Mountain Coal association and individual operators. Many Irish Catholics were members of the Ancient Order of Hibernians, a fraternal order with secret but entirely benevolent printed ritual.

As early as 1862 a newspaper account of coal-mine violence assigned blame to the "Molly Maguires," which in Ireland 20 years before had been an antilandlord agitational group. By the mid-1870s the mine operators and much of the public came to believe that sabotage and certain murders were the work of "Mollies" and that these were local Hibernian leaders, perhaps associated in an inner order, who were dedicated to violence. It appears that some Hibernian lodges in anthracite counties were then in the control of lawless men who found the "Molly" label a help in local politics and in engineering deeds of violence.

Franklin B. Gowen (1836–89), president of the Philadelphia and Reading Railroad and its Coal and Iron company, placed James McParlan, a member of the National Detective agency, among the Irish Catholics of the area in 1873. McParlan gained admission to the Hibernians and won the full confidence of local leaders, reporting daily to his employers. In 1876–77, in a series of sensational trials, McParlan testified on the inner workings of the local "Mollies." By 1880, 19 men were hanged and others imprisoned, and consequently the violent acts ceased and the society

was disbanded. Some injustices may have resulted, however, as guilt by association conquered the local mind, impressed overwhelmingly non-Irish juries and intimidated potential witnesses for the defense. Sir Arthur Conan Doyle made McParlan's exploit the subject of a dramatic story, *The Valley of Fear* (1915).

There is some justification for considering the Molly Maguire episode as an aspect of the labour struggles in the coal mines. Yet those convicted of violence were not orthodox trade-union leaders, and murders committed under "Molly" auspices often avenged personal grievances. Court convictions, publicity and more prosperous times apparently combined to bring the era of violence to a close.

**MOLNÁR, FERENC** (1878–1952), Hungarian playwright and novelist, one of the Hungarian dramatists best-known outside his own country, was born in Budapest on Jan. 12, 1878. His early career was in journalism and during World War I he was a war correspondent. He moved to the United States in 1940 and died in New York on April 1, 1952.

Molnár published his first short stories at the age of 19, and achieved his first great success with the play *Az ördög* (1907; Eng. trans., *The Devil*, 1908), in which he showed himself an accomplished master of stagecraft and witty dialogue and an expert chronicler of the contemporary high society of Budapest. Many of his plays, *e.g.*, *Liliom* (1909; Eng. trans., 1921), *A hattyú* (1920; Eng. trans., *The Swan*, 1929), *A vörös malom* (1923; Eng. trans., *The Red Mill*, 1932), were successfully played abroad, particularly in Austria, Germany and the United States. Some of them were adapted for the screen. Unfortunately, most of these translations and adaptations give a distorted, commercialized picture of Molnár's gifts of characterization, and water down his bitter cynicism and biting irony.

Some of Molnár's short stories, *e.g.*, those published under the title *Muzsika* (1908), are masterpieces, concise and often deeply moving. They reveal Molnár's sympathy with the poor and the underdog, and his ability to see the social and human problems behind the glittering façade of society life. Although capable of making a correct diagnosis, Molnár was unwilling to advocate any cure. Often moved, but never shocked, he depicted the victory of evil, of egoism, of immorality, with a touch light enough to amuse his public. A fine playwright and short-story writer, Molnár was a weak novelist. Only *A Pál-utcai fiuk* (1907; Eng. trans., *The Paul Street Boys*, 1927) achieved a well-deserved success.

(Ds. Sr.)

**MOLOCH** (MOLECH), the name of the divinity to whom child sacrifices were offered in the later days of the Hebrew kingdom (*e.g.*, II Kings xxiii, 10). Since the consonants (*mlk*) are simply those of the common Hebrew word for "king" (*melek*), it is probable that the latter was the original form of the name; the form *molek* arises from combining these consonants with the vowels of *bosheth*, meaning "shame," a derogatory title frequently substituted by Old Testament editors in proper names containing the element "baal" (*q.v.*), as in Ish-bosheth (II Sam. ii, 8) for Eshbaal (I Chron. viii, 33).

In the present edition of the Hebrew text the reader is undoubtedly intended to regard Molech as a foreign deity who had been illegitimately given a place in Israel's worship as a result of the syncretistic policies of certain apostate kings. One passage of the Hebrew Bible (I Kings xi, 7) explicitly identifies Molech with Milcom, the god of the Ammonites (*cf.* verse 5), but this identification is not original (the Greek version having preserved a different text). The identification, though incorrect, is instructive, since the very fact that the Ammonite god had a name involving the consonants of the word for king (*mlk-m*) shows how natural it was for the ancient Semites to think in terms of the kingship of deity. Foreign gods, bearing names of good Mesopotamian types, compounded with *melek*, are also mentioned in II Kings xvii, 31—in connection, significantly, with child sacrifice. Evidence from Mari, on the middle Euphrates, shows that a god named *muluk* was worshiped there in the 19th century B.C. Despite this evidence that gods with names similar to Molech were known in neighbouring countries, and the knowledge that the worship of imported deities was at certain periods encouraged in Israel, it seems unlikely that Molech in the Old Testament is the name of a foreign god. The deity to whom child sacrifice was offered was Yahweh, the chief—and, for normative Hebrew religion, the only—god of the nation, honoured in this connection as "the King." So repulsive was this abnormal practice, largely confined to the apostatizing reigns of Ahaz (II Kings xvi, 3) and Manasseh (II Kings xxi, 6), that the later Hebrews transformed the divine title associated with it into the artificial name Molech, as though the sacrifices had indeed been offered to a foreign god.

An attempt by O. Eissfeldt to show that "Molech" was originally the technical name for a legitimate sacrificial offering (*molk*), later distorted into a proper name, has not met with general acceptance, although his evidence is deserving of further study. It is unlikely that child sacrifice was ever regarded, in historical times, as a normal part of Israelite religion (*see* Ps. cvi, 37; Isa. lvii, 4 *et seq.*; Jer. xxxii, 35; Ezek. xvi, 20; Mic. vi, 7 *et seq.*); its occasional appearance was due either to a recrudescence of ancient superstition in times of special peril or to foreign influence.

(R. C. De.)

**MOLOTOV, VYACHESLAV MIKHAILOVICH** (1890– ), Soviet Communist leader, of Russian nationality, who as prime minister (1930–41) and as foreign minister (1939–49 and 1953–56) became known for his dogmatic rigidity. He was born on March 9, 1890, in the village of Kukarka (now Sovetsk), in Vyatka province, of middle-class parents whose name was Skryabin. In 1902 he entered the secondary school in Kazan; and in 1906 he joined the Communist party and engaged in revolutionary activity among the students. For this he was arrested in 1909 and deported to the Vologda region. After his release in 1911, he went to St. Petersburg, studied at the Polytechnic institute there and became at the same time a full-time organizer for the Bolsheviks. In 1912 he helped found the newspaper *Pravda*. He was again arrested in 1915 in Moscow and deported to Manzurka in Irkutsk province. Escaping in 1916, he returned to Petrograd and entered the Russian committee of the party. After the Revolution of 1917, Molotov occupied several posts in the provincial organization of the Communist party, and in 1921 was made a member and secretary of the central committee and a candidate member of the Politburo. In Jan. 1926 he became a full member of the Politburo, a position that he retained until 1957. He became one of Stalin's closest and most self-effacing collaborators. In Dec. 1930 he was made chairman of the council of the people's commissars (prime minister); and for the next ten years he concerned himself mainly with internal affairs and the country's industrial expansion.

In May 1939 Molotov was made commissar of foreign affairs in succession to Maksim Litvinov. He was thus responsible for negotiating the nonaggression pact with Germany that led to the outbreak of World War II. In May 1941 Stalin became prime minister, with Molotov as his first deputy. But after the German invasion it was Molotov who first spoke to the Soviet people and called for resistance. Throughout the war he served as deputy chairman (to Stalin) of the state defense committee, which directed the war effort. He visited Great Britain and the United States in 1942 to lay the foundations of the alliance with the western powers. He attended all the major interallied wartime and postwar conferences and was principal Soviet representative to the United Nations. He earned a reputation for uncompromising hostility to the west and to any deviation from Stalinist policies. In March 1949 he gave up his post as foreign minister to Andrei Y. Vyshinski.

Molotov presided over the opening of the 19th party congress in 1952. On Stalin's death in March 1953, he remained a member of the party presidium (as the Politburo was then called) and a first deputy prime minister and became minister of foreign affairs once more. In the conflicts that developed over the succession to Stalin, he was regarded as one of Nikita S. Khrushchev's principal opponents. He ceased to be foreign minister in June 1956

and was given the relatively unimportant ministry of state control in Nov. 1956. At the central committee meeting in June 1957, at which the conflicts came to a head, Molotov was deprived of all his high positions. Of Khrushchev's opponents he alone was allowed to abstain from voting in self-condemnation and was given a post abroad as ambassador to Mongolia. In Sept. 1960 he was appointed permanent Soviet delegate to the International Atomic Energy agency in Vienna. Recalled in Nov. 1961, he stepped out of public view in Feb. 1962. In April 1964 a secretary of the C.P.S.U. said that Molotov had been "thrown out of our party" but gave no details. (D. Fp.)

**MOLTKE, ADAM GOTTLOB,** COUNT (1710–1792), favourite and influential adviser of the Danish king Frederick V, was born on Nov. 10 or 11, 1710, at Walkendorf in Mecklenburg. When he was still a child his father moved to Denmark, where two uncles were already established, one as equerry to Prince Charles (d. 1729), brother of Frederick IV. In 1722 a post was obtained for the young Moltke as page to the crown prince, afterward Christian VI. In 1730 he became a chamberlain (*kammerpage*) to the future Frederick V, then only seven years old. In 1743 Moltke became Frederick's *hofmarskal* (court marshal or master of the household), an office which he retained after Frederick's accession in 1746. Frederick made him a privy councilor in 1747 and gave him the estate of Bregentved. Moltke was created a landgrave in 1750.

Moltke's influence soon became so great that a foreign diplomat declared that he could make and unmake ministers at will. He opposed liberal projects for the emancipation of serfs; but as one of the largest landowners in Denmark he did service to agriculture by introducing scientific and technical improvements.

Frederick V died in Moltke's arms on Jan. 14, 1766. Dismissed from his most important offices by the new king, Christian VII, Moltke was recalled in 1767 to help with agrarian reform. Again dismissed on Dec. 10, 1770, he retired to Bregentved. He died there on Sept. 25, 1792. His interesting memoirs, written in German, were published in 1870.

(F. Sk.)

**MOLTKE, ADAM WILHELM,** COUNT (1785–1864), Danish statesman, prime minister of the first government responsible to parliament in Denmark, was born at Einsiedelsborg in Fünen on Aug. 25, 1785, the son of the minister Joachim Godske Moltke and a grandson of Adam Gottlob Moltke. After completing his legal studies in 1805 he became assessor of the supreme court in 1809, a deputy at the *rentekammer* (exchequer) in 1812 and a member of the national debt commission in 1816. He succeeded his father as count of Bregentved in Oct. 1818. He became minister of finance in 1831 under Frederick VI (d. 1839) and president of the *rentekammer* in 1845 under Christian VIII (d. Jan. 1848). When Frederick VII renounced absolute rule in March 1848 and a representative government was set up, Moltke became prime minister. The mere fact that a distinguished statesman who had served the last two absolute kings of Denmark now voluntarily placed himself at the head of a ministry which included the most advanced of the National Liberals gave the new government prestige. It was this administration which introduced the constitution of June 5, 1849. Moltke was responsible for finance in the new government, but exchanged that portfolio for foreign affairs and Schleswig in Nov. 1848. He gave up these responsibilities in Aug. 1850 and resigned as prime minister on Jan. 27, 1852. Moltke was a member of the *landsting* (upper house) from 1849 to 1860, and was a member of the consultative *rigsraad* from 1854 to 1861. He died in Copenhagen on Feb. 15, 1864.

(F. Sk.)

**MOLTKE, HELMUTH JOHANNES LUDWIG VON** (1848–1916), German army officer and chief of the general staff at the beginning of World War I, was born at Gersdorff in Mecklenburg on May 25, 1848, the nephew of the great H. K. B. von Moltke. He became his uncle's adjutant in 1882 and subsequently commanded several guards' regiments. His dashing appearance and courteous manner brought him to the notice of the emperors William I and William II. This patronage, together with the inheritance of a great name, was to result in responsibilities for which he was totally unsuited.

Moltke became quartermaster general in 1903 and chief of the general staff, in succession to Alfred von Schlieffen (*q.v.*), in 1906. He thus inherited Schlieffen's master plan for war on two fronts against France and Russia, and his principal duty was to revise this plan to meet modern conditions. His task was a difficult one; he had frequently to combat the emperor's inflated ideas of his own military ability; Germany's potential ally, Austria-Hungary, constantly pressed for greater German strength to be deployed in the east; and the war ministry, which controlled armaments, was excessively conservative on the question of new weapons and equipment. Partly because of ill health but mainly because of lack of personality, Moltke failed to overcome these difficulties. His modification of the Schlieffen plan left the right wing of the armies in the west too weak, with the result that the speedy victory over France, which was essential to German strategy, did not materialize.

When war broke out in 1914 Moltke did not measure up to requirements. The campaign against France was characterized by lack of co-ordination by supreme headquarters; instead of a quick victory, stalemate and trench warfare supervened. On Sept. 14, 1914, Moltke was relieved of all executive responsibility in favour of Erich von Falkenhayn, though remaining as nominal chief of the general staff till the end of the year. He was then given the post of deputy chief of staff at home. He died in Berlin on June 18, 1916. His *Erinnerungen, Briefe, Dokumente, 1877–1916*, edited by Elisa von Moltke, appeared in 1922.

(C. N. B.)

**MOLTKE, HELMUTH KARL BERNHARD,** GRAF VON (1800–1891), chief of the Prussian and German general staff, the organizer of victory in the Seven Weeks' War and in the Franco-German War of 1870–71, was born on Oct. 26, 1800, at Parchim in Mecklenburg, of an aristocratic but impoverished family. His father was a man of unstable character, and the son undoubtedly inherited his great ability as a thinker and organizer from his mother, who came from an old Lübeck family.

Moltke was educated with the royal cadet corps at Copenhagen in Denmark, after which he joined a Danish infantry regiment. His early career was not a happy one, as he was extremely poor and had indifferent health. After a visit to Berlin in 1821 he decided to become a Prussian officer; and though his brothers remained in the Danish service, he became a lieutenant in the *Leibgrenadier* regiment. The next few years were spent chiefly at Frankfurt an der Oder, where, to improve his financial position, he took up literary work. He wrote a short novel, *Die beiden Freunde* (1827), and a military study of the Polish insurrection of 1830–31. He accepted a publisher's offer to translate Edward Gibbon's *Decline and Fall of the Roman Empire* but, after most of the work was completed, the publisher failed to produce it. Moltke then spent some years in the topographical office, but in 1833 was transferred to the Prussian general staff. Two years later he went to Turkey to learn the language and study conditions in the country and also to advise Sultan Mahmud II's government on the modernization of the Turkish army. Soon after his arrival, however, contrary to the original intention, Moltke entered the Turkish service; and in 1839, in the capacity of adviser, he accompanied the Turkish general Hafiz Pasha to Syria. The failure of the Turks to dislodge the Egyptian forces (under Muhammad Ali's son Ibrahim) from Syria was partly due to neglect of Moltke's advice.

Returning to Germany at the end of 1839, Moltke re-entered the Prussian service. He published a selection of his letters from Turkey, *Briefe über Zustände und Begebenheiten in der Türkei*, in 1841. In April 1842 he married Marie Burt, stepdaughter of his sister Augusta (who had married an English landowner, J. H. Burt, in 1834); and though he had no children, the marriage proved a very happy one. Further writings of this period were an essay on railway construction and operation (1843) and a his-

tory of the Russo-Turkish campaigning of 1828–29 in the Balkans (1845). Late in 1845, however, Moltke was appointed personal aide-de-camp to the invalid Prince Henry of Prussia, who was living privately in Rome. Though this appointment ended with Prince Henry's death in July 1846, it gave Moltke the opportunity to begin work on a splendid topographical map of Rome and its vicinity (published in 1852) and to write his "Wanderungen um Rom" (published in his *Wanderbuch*, 1879). Moreover, when the warship bringing Prince Henry's body back to Germany reached Gibraltar, Moltke left it and made his own way home across Spain, recording his impressions in his "Tagebuchblätter aus Spanien" (also published in the *Wanderbuch*). He has a place among the best writers of 19th-century German prose.

Working again for the Prussian general staff (at Coblenz in 1847, in Berlin in 1848 and subsequently in Magdeburg), Moltke started thinking about the bigger problems which confronted Prussia: the unification of Germany and the problem of security for a country surrounded by potential enemies and with no natural frontiers. He was convinced that only the army could provide a satisfactory solution to these problems; and his delight in the victory for reaction after the revolution of 1848–49 was expressed in 1850, when he wrote to his brother that the curtain had come down on Prussia's worst enemy—democracy.

A colonel from 1851, Moltke was in 1855 appointed personal aide-de-camp to Prince Frederick William, the future king of Prussia and German emperor (*see* FREDERICK III). This post involved more travels: to Scotland and thence to England in 1855–56; to Russia and to France in 1856. Even so, apart from the period of his Turkish service and his brief stay in Rome, Moltke's career up to this time had been mostly dull routine or concerned rather with the affairs of his princely masters than with the profession of arms. Only as junior regimental officer in Turkey had he commanded troops. To the French empress Eugénie, who met him in Paris in 1856, and to other contemporaries, he seemed a deep and intelligent thinker, but a man of silence.

**Chief of the General Staff.**—This was the man who was selected as chief of the Prussian general staff in 1857 and confirmed in that office in Sept. 1858. Thus began the era of the great triumvirate—Otto von Bismarck (chancellor), Moltke (chief of the general staff) and Albrecht von Roon (minister of war)—which within 13 years was to change the map of Europe, to procure the humiliation of France and to found the German empire under the leadership of Prussia.

The new chief of the general staff entered upon his duties at a time when a technical revolution was changing the whole conception of war. The rearmament of the German infantry with the breech-loading needle gun had been proceeding since 1848 and was almost complete. Breech-loading guns for the artillery were on the way, but were not finally introduced until 1861. These, however, were mere details of armament; much more significant was the introduction and rapid development of railways.

Moltke was the first military man to appreciate the important role which railways could play in the deployment, subsequent movement and supply of armies on a great scale. Hitherto the movement of troops had been restricted by the paucity of road communications; this had not only often set a limit to the size of armies and greatly increased the difficulties of supply, but also frequently led to the suspension of operations in the autumn, when troops were wont to go into winter quarters until the following spring. Thus the aim of strategy of the great captains, from Alexander the Great to Napoleon, had been to bring the strongest possible force, in the best possible condition, onto a small battlefield where the whole army would be within sight—almost within voice control—of its commander. Moltke saw that the advent of railways had changed this. He appreciated that many more men and much more equipment could be deployed much faster on vastly wider frontages. In place of battlefields of a few square miles there would be long battlefronts of perhaps hundreds of miles. The limited flank attack by a few battalions would give place to wide turning movements by armies of many divisions. Supplied by a network of railways, troops would be able to keep the field in all kinds of weather throughout the year.

Moltke at the same time appreciated that a new technique and a much more highly trained body of staff officers would be required to realize his new conception of warfare. The mounted staff officer with his purely local outlook would give way to one with a much wider view, capable of compiling intricate railway movement tables for vast numbers of men and animals and their equipment and arranging for daily trainloads of supplies. He saw too that changes were necessary in another direction. Whereas previously commanders had kept a very tight hold on their subordinates and had been able always to give short and explicit orders (whether verbal or written), it was clear to Moltke that this system would not work in an army of perhaps millions locked in battle along a front which might extend for hundreds of miles. He therefore instituted the system of "general directives" (known in World War II as "operation instructions"), in place of rigid "operation orders." In these the recipient was given a long-term task in general terms, but was allowed considerable latitude and was expected to use his discretion and initiative in carrying it out. When Moltke joined the general staff, its "chairborne" officers were held in little esteem by the "real" soldiers. It was Moltke who built up the Prussian general-staff system, which eventually became the model for all armies organized on modern lines.

Moltke was more fortunate than many who have had to initiate reforms and new methods. He became chief of the general staff in 1857 and it was not until 1870 that the really big test came. During these 13 years he was able to perfect the system, train a new type of staff officer and integrate into the military system civilian bodies such as the ministry of commerce and the newly formed railway department. Moreover, the comparatively minor ventures in which Prussia was involved between 1857 and 1870—the short war against Denmark in 1864 and the Seven Weeks' War (*q.v.*) against Austria and some of the other German states in 1866—provided the best possible experience for testing the new system and correcting any shortcomings.

The campaign of 1866 was particularly important as a test for Moltke's new theories and methods, still distrusted and occasionally disobeyed by the older generals. The move forward to the assembly positions in May and early June involved the deployment of three armies, of a strength of about 256,000 men, on an initial front of about 260 mi. After some preliminary actions the campaign was virtually ended by the decisive Prussian victory at Königgrätz. This cost Austria 45,000 casualties and Prussia 9,000. Nevertheless, Moltke had no cause for complacency. Many defects were revealed, the most conspicuous being the poor standard of training of some staff officers and the inadequacy of the intelligence service. The experience was invaluable as a curtain raiser for the bigger struggle which was to follow in 1870.

By this time the chief of the general staff had begun to show the qualities of a great soldier. In spite of shortcomings in the system and some mistakes, the quick success against Austria had vindicated Moltke's theories and greatly enhanced his prestige. He possessed the great virtue of recognizing his mistakes, and his subordinates now responded readily to the measures that he took to prevent their repetition.

**Franco-German War.**—The basic cause of the Franco-German War (*q.v.*) of 1870–71 was the same as that of 1866—Prussia's desire to seize the opportunity to eliminate a dangerous rival. Moltke and Roon had not wasted the years since the war against Austria and were able by the end of 1869 to assure Bismarck that the Prussian army was capable of defeating the French and that in their judgment the time was opportune.

Hostilities began on July 19, 1870. Moltke's aim was the speedy capture of Paris, which he judged would be decisive, and for this purpose he deployed three armies of a total strength of about 384,000 men. Bitter fighting took place in the early stages, and on Sept. 1 the Germans won their great victory at Sedan. This left the French without an organized army and politically brought about the downfall of the second empire; but it did not bring peace. The French continued to fight a losing war until the end of Feb. 1871, when peace talks were started. The French army had fought well and had won some notable local victories but was completely outmatched by the Germans' modern system of direc-

tion and command and by their superior staff work. It was a great triumph for Moltke, who had evolved and perfected the system.

Moltke continued as chief of the general staff for another 17 years. With the increasing threat from Russia much of his time was spent in study and in preparing the army for a war on two fronts—work to be continued by Alfred von Schlieffen (*q.v.*). He was created a field marshal in June 1871.

Disapproving of what he knew and saw of the new emperor William II, Moltke resigned in Aug. 1888 and went to live on the estate at Kreisau which had been his reward in 1866. He died on a visit to Berlin, on April 24, 1891. A collected edition of his writings and reminiscences, in 8 volumes, was published in 1891–93, an edition of his military works, in 15 volumes, in 1892–1912.

**MOLUCCAS** (MALUKU), islands of the Malay archipelago (*q.v.*) lying between Celebes (Sulawesi) on the west, New Guinea on the east, Timor on the south and the open Pacific ocean on the north. Total area approximately 28,766 sq.mi. Pop. (1961) 789,534. These islands constitute the Indonesian province of Maluku, subdivided as follows: (1) Maluku Utara (North Moluccas) *kabupaten* (regency), comprising the Ternate group (of which Halmahera is the largest), the Batjan and Obi groups; (2) Maluku Tengah (Central Moluccas) *kabupaten*, with Ceram (Seram), Buru, Wetar and the Banda Islands; (3) the municipality of Amboina (Ambon), off the south coast of Ceram, with the provincial capital; (4) Maluku Tenggara (Southeast Moluccas) *kabupaten*, comprising the Tanimbar group, Babar, the Kai and the Aru islands. As a token of Indonesia's claim on Netherlands New Guinea (realized in 1963), the island of Tidore and central Halmahera were in 1958 separated from Maluku province, as the cradle area for the new province of Irian Barat (Western New Guinea), and were so considered in the 1961 census.

**Physical Geography.**—The Moluccas are tectonically an unstable zone; earthquakes are frequent and several islands have active volcanoes, especially Ternate and Banda. Most of the islands are mountainous (more than 9,000 ft. in Ceram), but the Tanimbar and Aru islands are low and swampy. Ceram contains an oil field. Temperatures at sea level fluctuate slightly from about 25° C. (76° F.) in the coolest month to 29° (84°) in the warmest month. Rainfall varies according to exposure from 80 to 150 in. annually. In some parts the evergreen rain forest, formerly covering most of the islands, has been cut down and the land cultivated. There are patches of open savanna, and the coasts are fringed with mangrove swamps. In fauna and flora the Moluccas are a transition zone between Asian and Australian forms, with many endemic species. In the 17th century G. E. Rumpf (Rumphius) wrote there his great book on native flora, and in the 19th century A. R. Wallace developed there his concept of evolution.

**People.**—The inhabitants show great diversity in ethnic type because this area is a transition zone between the Malays to the west and the Papuans to the east. Moreover, there has been much admixture with Javanese, Portuguese and Dutch. In general the way of life is primitive, but the small islands and the coastal fringes of the larger islands are somewhat more advanced, with Christianity and Islam as the dominant faiths; the people of the interior are still animists. There are different languages, all belonging to the Malayo-Polynesian family, except for those of north Halmahera. Most people secure their food by collecting the starch of the sago palm, fishing and hunting. Coconuts are widely grown and copra is the main export product.

**History.**—The cloves of the northern Moluccas and the nutmegs of the central islands were a focus of early Asian trade long before Europeans started their search for the legendary "Spice Islands." In the 16th century Ternate and Tidore, tiny islands off the west coast of Halmahera, were the seats of rival sultanates, each controlling part of the spice production. The Portuguese arrived in 1512 and made an alliance with the sultan of Ternate. There was a prolonged conflict between Portugal and Spain over control of the islands. The Dutch came in 1599, soon gained predominance in the south (Amboina, Banda) and gradually eliminated their rivals, including the English. Part of the population was converted to Christianity, especially on Amboina. The cruel struggles for monopoly meant great loss of life and property. The Dutch earned large profits, but by the end of the 18th century the spice trade had greatly diminished and the Moluccas became an economic backwater. After World War II the Moluccas became a part of the state of East Indonesia, and as such in 1949 an autonomous member of the independent United States of Indonesia. The change to a unitary Indonesian republic in 1950 caused the Christian Amboinese to revolt (*see* AMBOINA).

**MOLY,** in modern times the name applied to a species of onionlike bulbous herb (*Allium moly*), native of southern Europe and grown in borders and rock gardens for its bright-yellow flowers. It bears no relation to the legendary moly, a mysterious plant with magical powers described in Homer, *Odyssey*, x. 302–306. Hermes pulls it up and gives it to Odysseus as a protection against the arts of Circe. It is further described as "having a black root and a flower like milk, and hard for mortals to pull up." This classical moly, the name of which is probably magical and derived perhaps from Phoenician or Egyptian sources, cannot be identified with certainty.

**MOLYBDENITE,** a mineral consisting of molybdenum disulfide $MoS_2$, containing 60% molybdenum. It is the chief source of molybdenum, which is used in the manufacture of special steels, such as tool steel, to which it imparts greater hardness and strength. The metal is used in the electrical industry, and certain compounds are used in chemistry, ceramics and dyeing.

Molybdenite closely resembles graphite, has the same greasy feel and likewise is soft enough to mark paper. Both minerals have a layer structure and as a result have perfect basal cleavage and are usually foliated. The name comes from the Greek *molybdos* (lead), with which both graphite and molybdenite were confused. The latter was first identified by P. J. Hjelm, who in 1782 discovered the element molybdenum in this mineral. It is distinguished from graphite by its greater specific gravity (4.7), a bluish lead-gray colour and a greenish streak on glazed porcelain, in contrast with the grayish streak of graphite. Its common association with quartz or acidic rocks may also help distinguish it, for graphite is more commonly associated with metamorphosed limestone and basic rocks. Molybdenite is hexagonal, but the six-sided platy crystals are rare. It is commonly in disseminated plates or scales which are flexible but not elastic. The lustre is bright metallic.

Molybdenite occurs in crystalline rocks, such as granites, pegmatites and schists, and also in quartz veins. It is fairly common in small quantities as one of the first minerals formed in high temperature veins, along with scheelite, wolframite, topaz and fluorite. The United States has been the chief producer, usually accounting for at least 70% of the world's production. In the second half of the 20th century Colorado was the leading state, followed by Utah, Arizona, New Mexico and California. Other major producers are the Soviet Union, Chile and the People's Republic of China. (L. S. R.; X.)

**MOLYBDENUM** is a metallic element resembling steel in colour and having an unusually high melting point of about 2,610° C. (4,730° F.). It is one of the most important of the alloying elements used in steels, irons and certain nonferrous alloys. It is also one of the most commonly used of the refractory metals.

Molybdenum (symbol Mo, element number 42, atomic weight 95.94) is in Group VI B of the periodic system and is therefore related to chromium and tungsten. There are seven natural stable isotopes with mass numbers (in order of decreasing abundance) 98, 96, 92, 95, 100, 97, 94; several artificial radioactive isotopes (91, 93, 99, 101, 102, 105) are known. The arrangement of electrons in the unfilled N and O shells is $4s^2$, $4p^6$, $4d^5$, $5s^1$.

## OCCURRENCE AND PRODUCTION

Molybdenum is not found free in nature. The only important production is from deposits containing the mineral molybdenite,

$MoS_2$; however, some powellite—calcium tungstomolybdate, $Ca(Mo, W)O_4$—a secondary mineral of the scheelite group, is treated to recover molybdenum and deposits containing wulfenite, lead molybdate, $PbMoO_4$, have been worked.

After World War I, when the usefulness of alloys containing molybdenum was recognized, the United States supplied about 90% of the world's production, most of which usually came from the Climax mine at Climax, Colo. The next largest source was the copper industry which obtains molybdenite concentrate as a by-product from several mines in the United States and Chile. Just after the middle of the 20th century, world production of molybdenum in concentrates was fluctuating from about 50,000,000 to 90,000,000 lb. a year.

At Climax, where the mine is operated primarily for the recovery of molybdenite concentrate, the ore may contain from 0.3% to 0.6% $MoS_2$. Separation of molybdenite concentrate is accomplished by crushing, fine grinding and oil flotation. Commercial concentrate contains about 80% to 95% $MoS_2$ on a dry basis.

The molybdenum sulfide in the concentrate is converted by roasting to molybdic oxide ($MoO_3$). There is no removal in this process of the siliceous gangue contained in the concentrate. The product may be referred to as technical molybdic oxide or roasted molybdenite concentrate.

Ferromolybdenum is produced from technical oxide by either thermite or electric furnace processes and usually contains between 55%–75% molybdenum. Molybdenum may be added to steel in the furnace in the form of technical oxide or ferromolybdenum. Ferromolybdenum is generally used for ladle additions to either steel or iron. Metallic molybdenum of high purity may be used in making the nonferrous alloys for high temperature service. *See* also METALLURGY.

## CHARACTERISTICS AND USES

**Metallic Molybdenum.**—Molybdenum powder is produced by the hydrogen reduction of purified molybdic oxide or ammonium molybdate. Metal boats containing the oxide are pushed through heated tubes reaching a maximum temperature of about 1,050° C. (1,922° F.). The process is commonly carried out in two stages; the first step produces molybdenum dioxide at about 600° C. (1,112° F.) which is reduced to metal at 1,000° to 1,050° C. (1,832° to 1,922° F.) in the second stage. Conversion of powder to massive metal may be carried out by either of two methods: the powder metallurgy (*q.v.*) process developed about 1910 or the arc-casting process developed about 1944.

In the first process, the powder is compacted at room temperature into ingots or bars under pressures of about 10 to 20 tons per square inch. The compacts are sintered by heating in hydrogen or vacuum at 1,100° to 2,200° C. (2,012° to 3,992° F.).

In the arc-casting process, a partially sintered bar serves as a consumable electrode and is melted into a water-cooled mold usually made of copper. The electrode may be prefabricated or may be continuously pressed and sintered within the melting unit. The operation is carried out in a high vacuum or an atmosphere of purified inert gases. In this process, alloying elements can readily be incorporated by mixing them with the molybdenum powder from which the electrode is made.

Small powder metallurgy compacts to be made into rod or wire may be worked by swaging or rolling, starting at about 1,300° C. (2,372° F.). After suitable reduction, wire may be made by drawing through carbide dies or, for finer sizes, through diamond dies. Arc-cast ingots may be broken down by extrusion at about 1,100° to 1,210° C. (2,012° to 2,390° F.). The extrusions may be rolled into bar products. For the production of plates and sheets, extrusions may be rolled or forged into sheet bars. They may also be used for the production of hand or die forgings.

Among the properties of metallic molybdenum responsible for its commercial use are its very high melting point, superior strength at high temperatures, high modulus of elasticity, high electrical and thermal conductivity, low coefficient of thermal expansion and relatively low absorption cross section for thermal neutrons. It is resistant to several common chemical solutions including hydrochloric, sulfuric, phosphoric and hydrofluoric acids under many conditions of concentration and temperature. It is attacked by oxidizing acids, molten oxidizing salts and fused alkalis. It is rapidly oxidized in air at temperatures above about 500° C. (932° F.).

Metallic molybdenum has been widely used in electronic tubes for anodes, grids and support members. Rod or wire is used for heating elements in furnaces operating up to 1,700° C. (3,092° F.). Oxidation is avoided by using a reducing or inert atmosphere. Sprayed coatings of molybdenum make a firm bond to steel and some other metals, and show excellent resistance to wear. In the glass industry, molybdenum has been used for resistance heating electrodes, stirring devices and wear parts. Molybdenum and its alloys have also been used for various parts of high-temperature engines. When excessive oxidation might be encountered, protective coatings are necessary.

**Molybdenum as an Alloying Element.**—In the 1890s, the use of molybdenum in steel was studied by various investigators. Until about 1918, however, the commercial development of molybdenum steels was hindered by the high price and uncertain supply of molybdenum. The development of the mine at Climax and the experiences of steel fabricators with wartime molybdenum steels led to further development work and to the adoption in the 1920s of various molybdenum steels for peacetime purposes, notably by the automotive industry. In steels for automotive and other machine parts, molybdenum may be used as the principal alloying element or in conjunction with other elements, especially chromium and nickel.

In machine construction, alloy steel parts are generally hardened and tempered to increase their strength and resistance to wear. The principal reason for adding alloying elements is to make it possible to harden the parts by less rapid cooling, as by quenching in oil instead of water. The alloying elements are said to increase the hardenability of steel. Molybdenum is one of the most effective elements in this respect.

Molybdenum contributes to the toughness of quenched and tempered steels especially by helping to prevent the development of temper brittleness. This effect together with its contribution to hardenability has accounted for the use of molybdenum in many applications where maximum toughness is required as in armour plate and guns.

High-speed tool steels contain molybdenum or tungsten to develop the property known as red hardness, or ability to cut at a red heat. It has been known since about 1900 that one part by weight of molybdenum is substantially equivalent to two parts of tungsten, but the commercial development of molybdenum high-speed steels began about 1934. Such steels contain molybdenum or molybdenum and tungsten, together with chromium and vanadium. Molybdenum is also used in other types of tool steel and is added to various types of stainless steel to further improve their resistance to certain kinds of corrosion. Molybdenum increases the strength of steel at elevated temperatures and has been widely used, for example, in pipes, valves, forgings and fittings in superheated steam plants, in superheater tubing and in cracking-furnace tubes. Molybdenum increases the strength, toughness and uniformity of gray iron (*see* CAST IRON), in which it is extensively used.

As in steel, molybdenum also increases the hardenability and elevated temperature strength of gray iron. Molybdenum cast iron has been used in chilled rolls and also in grain rolls, for rolling metal, cast in sand molds to increase resistance to breakage, chipping, heat checking and spalling. In automobile engines, molybdenum cast irons can be used in camshafts and tappets. Many of the nickel-base and cobalt-base alloys which have been developed for high temperature use as in gas turbine parts contain molybdenum to increase their high temperature strength. Molybdenum is also used in certain nickel-base alloys developed primarily for resistance to corrosion in chemical solutions. (*See* also ALLOYS.)

**Compounds.**—Molybdenum exhibits valences of +2, +3, +4, +5 and +6; it is considered zero valent in the carbonyl $Mo(CO)_6$. The most important compound is the trioxide, $MoO_3$, from which most of the known compounds containing the element can be prepared. The oxide obtained by roasting molybdenite in air can

be purified by sublimation, or pure oxide may be obtained by thermal decomposition of ammonium molybdate.

Molybdic oxide has found use as a catalyst. Molybdate chrome orange, a brilliant pigment of high covering power, may be made with molybdic oxide or sodium molybdate, $Na_2MoO_4$, as a source of molybdenum; these compounds are also used in the production of molybdated dyes and pigments. Ammonium molybdate is used in the production of molybdenum metal powder, in the preparation of catalysts and as an analytical reagent, especially for the determination of phosphorus. Molybdenum disulfide, $MoS_2$, of adequate purity for use as a lubricant can be prepared from regular molybdenite concentrate by further grinding and flotation or by leaching with hydrofluoric acid. It may be used as an additive to greases and oils or as a dry film or solid lubricant. The pentachloride, $MoCl_5$, may be prepared by the action of chlorine on molybdenum powder. It has been used as a chlorination catalyst.

Molybdenum has been proved an essential trace element in plant nutrition; in legumes, it assists bacteria in fixing nitrogen. Sodium molybdate or molybdenum trioxide may also be used (*see* FERTILIZERS AND MANURES, *Secondary Elements*). *See* also references under "Molybdenum" in the Index.

**MOLYNEUX,** the name of a famous English family, one of whose members, Charles William Molyneux (d. 1795), was created 1st earl of Sefton in 1771, is derived from Moulineaux in France (Seine-Inférieure). The manor of Sefton in Lancashire was granted about the year 1100 by Roger, count of Poitou, to a member of the Molyneux family, probably one Robert de Molyneux, and has been held by the family ever since. A famous member of this family was Adam de Molyneux (d. 1450), bishop of Chichester and keeper of the privy seal. Richard Molyneux (*c.* 1594–1636) was created (1628) 1st Viscount Molyneux of Maryborough in the Irish peerage, a title now merged in the Irish earldom of Sefton. The present earl of Sefton is Hugh William Osbert Molyneux (1898– ).

Another Molyneux family of some importance is the Irish one, descended from Sir Thomas Molyneux (d. 1597), who, born in Calais, settled in Ireland in 1576 and became chancellor of the exchequer there. He was the great-grandfather of Sir Thomas Molyneux, Bart. (d. 1733), a well-known physician and zoologist, and of William Molyneux (d. 1698), the astronomer and philosopher, who was a friend of John Locke. William's son Samuel (d. 1728) was also a well-known astronomer.

**MOM:** *see* BAMUM.

**MOMBASA,** a town of Coast province, Kenya, East Africa, and the chief port for Kenya, Uganda and northeastern Tanganyika, is built on a coralline island about 3 mi. long and 2½ mi. wide, at the mouth of a deep arm of the Indian ocean. The population (Mombasa social survey census 1957) was 145,387 including 4,399 Europeans; the total population in 1962 was 178,400. Municipal area, including mainland districts, 27 sq.mi. The climate is warm and equable, with a mean maximum temperature of 86° F. and a mean minimum of 74° F. February and March are the warmest months, June and July the coolest. The annual rainfall averages 47.65 in.; the driest months are January through March, the mean relative humidity is 75%. Coral headlands enclose sandy bays and the striking vegetation includes mango and fig trees, coconut palms, flamboyant, baobab, bougainvillea and oleander. On the east side of the island Mombasa's old harbour serves dhows and coastal sailing vessels. On the west side Kilindini, the modern port, runs into the capacious harbourage of Port Reitz. Connections between island and mainland are by Nyali bridge and Makupa and Kipevu bridge-causeways; several ferries also carry vehicular and passenger traffic.

By the 1960s Mombasa had developed from an old-fashioned harbour town into a thriving modern seaport. Most Arab-style houses have been replaced by multistoried buildings. The commercial area is concentrated in the centre, but the movement of shipping and mercantile offices has been toward Kilindini. An industrial area covering 52 ac. is fully developed at Shimanzi in the northwest; Changamwe, on the mainland across the Makupa causeway, and the most recent industrial district, contains an oil refinery.

The old town clustered around Mombasa's old port is mainly occupied by Asian and Arab traders. The Portuguese relic Fort Jesus (1592), overlooking the old harbour, had been used as a prison since 1892, but in 1955 was handed over to the Kenya Royal National Parks administration for use as a museum. There are also Portuguese ruins of churches, watchtowers, blockhouses and remains of mosques. At the southeastern point of the island, government house and a golf club face the Indian ocean. Around a gardened square behind Fort Jesus are the treasury, municipal offices and head post office; near by stand the law courts and Mombasa club. Public buildings include Anglican and Roman Catholic cathedrals, mosques and temples; European, Asian, Arab and African schools; and hospitals. There are many hotels, clubs and cinemas, a theatre and a stadium.

The first train steamed from Mombasa to Lake Victoria in 1901. The rail terminus is in the centre of the island and the main line is carried by the Makupa causeway. The interterritorial East African Railways and Harbours administration maintains a daily service with up-country districts, Uganda and northern Tanganyika. Motor roads link the port with other parts of Kenya, and at Nairobi with the Cape-to-Cairo road. Local buses serve the town and all nearby points. From Port Reitz airport, about 6 mi. from the centre of the island, regular air services connect with transcontinental airlines at Nairobi and with other parts of East Africa. The landlocked port of Kilindini accommodates vessels of any size. Its first deep-water berth was built in 1926 and by the early 1960s it had 14, including those on the mainland at Kipevu. Passenger services connect the port with most parts of the world.

Mombasa is a market for the region's agricultural products, including coconuts, sisal, cotton, sugar, kapok, various fruits and vegetables, rice, maize and millet. The port handles the export of many of these and other goods such as coffee, minerals, soda ash, oilseed and cake. Industries include cement making, lime burning, coffee curing, brewing, machine shops, and the manufacture of glass, coconut oil, soap, aluminum ware and metal containers.

It is believed that Mombasa takes its name from Mombasa in Oman (Persian gulf). With the rise of Islam, Arabs established themselves on the East African coast and a Perso-Arabic settlement at Mombasa dates from about the 11th century. In 1331 the Arab traveler Ibn Batuta described it as "a large place," and in 1498 Vasco da Gama found it a seat of considerable commerce. The ruler of the city tried to entrap da Gama (or so the explorer thought) and with this began a series of Portuguese-Arab campaigns which gave full force to the island's Swahili name *Mvita* (war). The principal incidents were the capture and burning of the town by Francisco de Almeida (1505), Nuno da Cunha (1529) and Duarte de Menezes (1587), the revolt and flight (1631) of Yusuf ibn Hassan after massacring the Portuguese colony, and the three years' siege of Fort Jesus by the imam of Oman in 1696–98, ending in the expulsion of the Portuguese. From March 1728 to Nov. 1729 a Portuguese force from Goa once again held Mombasa, when they were finally driven out by Muscat Arabs.

In Dec. 1823 the ruling Mazrui family placed the city under British protection and in Feb. 1824 Lieut. J. J. Reitz was appointed commandant. He died soon after. The protectorate was never confirmed by the British government. The town was later captured by Said bin Sultan of Oman who, after repeated attacks, obtained possession in 1837. Said made Zanzibar his capital and Mombasa became of secondary importance. A revolt against Zanzibar in 1875 was put down with British assistance. In 1887 the town was handed over by the sultan of Zanzibar to the British for administration and it later became the capital of the East African protectorate (Kenya colony). In 1907 the seat of central government was removed to Nairobi. Mombasa became a municipality in 1928 and assumed council status in 1959; until Kenya became independent in 1963 Mombasa formed part of the sultanate of

Zanzibar and was included in Kenya protectorate as distinct from Kenya colony. (ED. R.)

**MOMMSEN, (CHRISTIAN MATTHIAS) THEODOR** (1817–1903), one of the greatest of 19th-century German classical historians as well as a notable scholar in jurisprudence, philology and numismatics, and winner of the Nobel prize for literature in 1902, was born at Garding, Schleswig, on Nov. 30, 1817. His years at Kiel university developed his talent for law, and a traveling scholarship to Italy led him to become a student of inscriptions, a classical scholar and a numismatist. The fruits of these years are to be seen in his *Inscriptiones regni Neapolitani Latinae* (1852), *Unteritalische Dialekte* (1850) and in the preliminary studies for his monumental *Geschichte des römischen Münzwesens* (1860). After a short period of editorial work in 1848, he began his academic career in the same year as professor of civil law at Leipzig. His liberal principles caused him to be dismissed as a result of political reaction in 1850. In 1852 he became professor of law in Zürich, and was transferred to Breslau in 1854. At the same time, the Prussian Academy of Sciences entrusted him with the publication of the giant *Corpus inscriptionum Latinarum*, and he moved to Berlin in 1858, becoming also professor of Roman history there in 1861. From 1874 he was permanent secretary of the philosophy and history section of the academy.

The three volumes of Mommsen's *Römische Geschichte* appeared while he was in Breslau (1854–56); all his later major works were published when he was in Berlin, including the *Corpus inscriptionum Latinarum* from 1863, the *Römische Staatsrecht* (1871–88), the fifth, supplementary volume of his *Römische Geschichte* in 1886 (volume four was never written) and the *Römische Strafrecht* (1899). In addition, he published numerous articles and editions, notably the *Digest* of Justinian, the Codex Theodosianus and the *Chronica* of Cassiodorus. He died on Nov. 1, 1903, in Berlin.

Mommsen embodied German 19th-century historical scholarship best by uniting jurisprudence and history, philology and archaeology. He saw in legal antiquities, inscriptions and coins the expression of social conditions, and gave administrative records the same weight as diplomatic ones. His work on the Roman legal system demonstrates most brilliantly how empirical observation and a critical interpretation of individual facts led him to a systematic grasp of great intellectual issues; and his *Römische Staatsrecht* down to Diocletian thus marks an epoch in the development of historical scholarship. The *Römische Geschichte* combines scholarly common sense with a passion for bringing the past to life. Objective though he was, he allowed himself personal judgments, reducing the stature of Cato, Cicero and Pompey and seeing in Caesar the inevitable and brilliant culmination of century-long constitutional development. Caesarism as a system, however, he condemned.

Toward religion Mommsen was indifferent, and he mocked at historical-philosophical speculation. The political ideas of his scholarly work are marked by his national and democratic faith. All his life he clung to the creed of 1848, hoping for a politically united and constitutional Germany. He was therefore reserved and critical toward Bismarck and increasingly skeptical of the attitude of the educated middle classes. He was a member of the German Progressive party from 1863 to 1867, a National Liberal from 1873 to 1879 in the Prussian *Landtag* and a member of the left-wing liberal secession in the *Reichstag* (1881–84). His extensive work as an organizer, however, prevented him from being drawn to mix history with politics. He created a school of epigraphy and numismatics, was for many years head of the *Auctores antiquissimi* section of the *Monumenta Germaniae historica*, founded the Archiv für Papyrusforschung, organized research on the Limes Germanicus and promoted the *Thesaurus linguae Latinae* (see LIMES). He supported the positivist development of particular disciplines and the mechanical aspects of scholarship, and he achieved an unequaled grasp of the totality of history.

BIBLIOGRAPHY.—Bibliography of Mommsen's writings down to 1887 in K. Zangemeister and E. Jacobs, *Mommsen als Schriftsteller* (1905), supplemented by A. Wucher, *T. Mommsen, Geschichtschreibung und Politik* (1956). *See* also A. Heuss, *T. Mommsen und das 19. Jahrhundert* (1956); L. Wickert, *T. Mommsen. Eine Biographie* (1959– ).

The *Römische Geschichte* has been translated into English as *The History of Rome* by W. P. Dickson (1862–75; new ed. 1868–86, including vol. 5, as the *Provinces*); in the "Everyman Series" (1911; reprinted 1929–30), abridged by C. Bryans and F. J. R. Hendy (1888; new ed. 1959); and by D. A. Saunders and J. H. Collins (1958). (FZ. W.)

**MOMORDICA,** a genus of annual or perennial vines belonging to the gourd family (Cucurbitaceae; *q.v.*), natives of the tropics, especially Africa, and known in cultivation chiefly as hothouse plants. They are grown for their ornamental fleshy fruits, which are oblong to cylindrical, orange to red, prickly or warted externally, and burst when ripe, generally with elastic force, into irregular valves. *M. balsamina* (balsam apple) is a very pretty annual, well adapted for trellises, etc., in tropical situations, as is also *M. charantia* (balsam pear), a somewhat larger species.

**MOMOTIDAE,** a family of tropical American birds comprising the small, greenish, jaylike motmots (*q.v.*).

**MOMUS,** in Greek mythology, the son of Night and the personification of censoriousness. He is frequently mentioned as a sort of licensed grumbler, finding fault with all that the gods do. He appears very seldom in serious works; a lost satyr play of Sophocles bore his name, and Lucian often introduces him.

**MON,** a historically significant minority people numbering in the 1960s about 350,000 in the eastern delta region of Burma and 65,000 in west central Thailand, now distinguishable from the Burmese only in language. The Mon were among the earliest Mongoloid people from west China who spread over the river lowlands of southeast Asia from the Irrawaddy delta to the Menam Chao Phya valley and south to the Kra isthmus. They are a remnant of the earliest known civilization of southeast Asia, having been exposed to Indian culture (Brahmanism) and Theravada Buddhism for more than a millennium prior to the arrival of Burmese and Thai. Principal ancient Mon sites in lower Burma were Thaton, Twante, Rangoon and Pegu. The 7th-century centre of power was the kingdom of Dvaravati at Lopburi on the lower Menam, an offshoot of the Khmer empire. In the early 9th century the centre of Mon power shifted west to Pegu on the lower Sittang river. There were Mon connections with the great Buddhist centre at Kancheepuram (Madras). Southward-migrating Burmese took over the Mon irrigation of the Kyaukse area in central Burma and this dry zone became their key economic area (culture hearth). Conquest of Thaton in 1057 by Anawrata (Anuruddha), first king of Burma, was culturally decisive: Mon monks and scriptures of Theravada Buddhism were based at the Burmese capital, Pagan; Pali superseded Sanskrit as the language of sacred books; the Burmese adopted the Mon alphabet and Talaing became the Burmese name for Mon. Burmese were brought into direct contact with Indian influences and the way was opened for late 12th-century contact with Buddhist centres in Ceylon. Intermittent warfare for supremacy between the Mon of Pegu and Burmese to the north was the principal feature of 11th- to 18th-century Burma history. The Mon bore the brunt of 16th-century Burmese-Siamese struggles; their land was laid waste and their people were conscripted for forced labour or military service. Desperate Mon rebellions were met with savage reprisals, resulting in periodic migrations of the Mon to Siam. Short-lived independence for the Mon (1740–1757) ended with the Burmese siege and sack of Pegu and Mon subjugation. Those Mon who were not enslaved found refuge in Siam. Lower Burma became depopulated and famine-stricken, and, when the British arrived in 1824, had reverted to uncultivated waste.

**MONACO** (PRINCIPAUTÉ DE MONACO), a sovereign principality on the northern Mediterranean coast, 9 mi. E. of Nice, France, is bounded on all land sides by the French *département* of Alpes Maritimes. Pop. (1961 census) 22,297 (20,441 permanent residents), including 3,039 Monégasques (citizens of Monaco), 12,869 French, 4,217 Italians and 598 British. Area 387.9 ac. (0.6 sq mi.).

The Phoenicians and later the Greeks had a temple on the

Monaco headland dedicated to Heracles, whose local surname Monoecus may be derived from a pre-Indo-European root *mon-*, "raised site" or "rock." Monoeci Portus, or Portus Herculis, is mentioned by later Latin writers. In 1070 the Genoese Grimaldi family entered into possession. The Grimaldi for the most part allied themselves with France until 1524, when Augustin sided with the emperor Charles V. Honoré I, Augustin's successor, was made marquis of Campagna and count of Canosa, and special privileges were granted. The *droit de mer*, or the right to 2% of the value of the merchandise in ships passing within sight of the fortress, originated with the Genoese and had been confirmed by Charles VIII in 1497. It was confirmed again in the treaty of Péronne (1641), whereby Honoré II re-allied his house with France, losing Canosa, etc., but becoming duke of the Valentinois. In 1731 Antoine I, Honoré's great-grandson, was succeeded by his daughter Louise Hippolyte, wife of Jacques de Goyon-Matignon, count of Torigny, who succeeded his wife and took the name of Grimaldi. In 1793 the national convention dispossessed the reigning family and annexed Monaco to France. The treaty of Paris (1814) restored the family; that of Vienna (1815) put Monaco under the protection of Sardinia. In 1861 Menton and Roquebrune were purchased by France. By the Franco-Monégasque treaty of Feb. 2, 1861, Monaco was restored to independent sovereignty, and a customs union was established with France by treaty in 1865.

In 1911 Prince Albert granted the principality a constitution, providing for an elected national council. In 1918 a Franco-Monégasque treaty was signed. This contained a clause providing that, in the event of the dynasty's becoming extinct, Monaco would become an autonomous state under French protection. Albert was succeeded in 1922 by his son Louis II, who in 1949 was succeeded by his grandson Rainier III (b. May 31, 1923), son of the hereditary princess Charlotte Louise Juliette and of Prince Pierre, comte de Polignac. In 1956 Rainier married Grace Patricia Kelly, U.S. motion-picture actress. A daughter, Caroline Louise Marguerite, was born on Jan. 23, 1957, and a son, Albert Alexandre Louis Pierre, on March 14, 1958.

In 1951 Monaco and France signed a convention of mutual administrative assistance concerning customs, taxes, posts, telecommunications and monopolies, which replaced previous agreements of 1912, 1925 and 1945. In Jan. 1959 Rainier suspended part of the constitution and dissolved the national council, and in 1961 he appointed instead a national assembly. However, when in 1962 a crisis in Franco-Monegasque relations appeared to threaten Monaco's independence, Rainier restored the council and granted a new, liberal constitution. The crisis arose chiefly because of Monaco's refusal to impose direct taxation in the principality. In April, France, claiming that tax exemption gave an unduly privileged position to firms established in Monaco, served the requisite six months' notice prior to abrogation of the 1951 convention. In October, French customs controls were set up along Monaco's frontier, but after lengthy negotiations a new fiscal convention was signed (May 18, 1963). This provided, in the main, for the payment of income tax at French rates by French citizens of less than five years' residence in Monaco and of company tax by Monégasque firms deriving more than 25% of their profits from outside the principality.

The national council of 18 members is elected for four years by adult male suffrage and *scrutin de liste*. Government is carried on by a minister of state (who must be a French citizen) and three state counselors, acting under the authority of the prince. The ministry is assisted by a council of state, nominated by the prince, which prepares laws and ordinances. Legislative power rests with the prince and the national council.

Monaco forms a single commune administered by an elected council, but it is divided into four sections (pop. 1961): Monaco-Ville (1,774), the old settlement on the summit of a rocky headland defended by ramparts; La Condamine (11,007), on the west of the bay, with a business district and the all-season port for yachtsmen and pleasure boats; Monte Carlo (*q.v.*; 9,516), with casino and hotels; and to the west the newer quarter of Fontvieille, where various light industries (*e.g.*, pharmaceuticals, cosmetics) have developed.

The judicial system, since 1819, has been based on the French. There is a court of first instance and a *juge de paix*, and by arrangement two Paris judges form a court of appeal. There is a semi-military police force. The bishopric dates from 1887 and is directly dependent on the Holy See. Primary and secondary education are provided by both church schools and secular institutions, and there is also a school of music.

In Monaco-Ville are the Roman Catholic cathedral of St. Nicholas (on the site of the ancient church), the medieval Genoese and Renaissance palace and Prince Albert's oceanographic museum (1910). Another museum contains prehistoric exhibits from the grottoes near Menton and Roman antiquities from La Turbie.

In 1861 François Blanc of Homburg obtained a 50-year concession to run gambling tables. This concession passed to a company and was subsequently extended. The Monégasques are forbidden access to the tables but are exempt from taxation. The casino and the issue of postage stamps are important sources of Monaco's revenue, and the principality also depends heavily on the tourist industry. The Monégasque franc is equivalent to the French franc; both are legal tender. Radio Monte Carlo and Télé Monte Carlo broadcast and televise commercially sponsored programs; Trans World Radio in Monte Carlo, maintained by voluntary contributions, transmits exclusively religious programs.

(K. F. E. X.)

**MONAGAS**, a state in eastern Venezuela, is bounded by the Orinoco river on the southeast, the Caño Mánamo on the east, the San Juan river and the Gulf of Paria on the northeast, and the states of Sucre and Anzoátegui on the north and west. Area 14,158 sq.mi. Pop. (1961) 246,217. Except for a coastal range on the north and marshes in the Orinoco delta area, Monagas is a land of savanna—typical llanos country. Cattle raising is dominant over most of the state, though the usual list of Venezuelan crops is grown in the northern uplands. Monagas has one of the largest oil-bearing areas in eastern Venezuela; among the principal fields are Campo Temblador, Campo Santa Barabara, Campo Jose-

pin and Campo Quiriquire. Pipelines connect the fields with the Caripito refinery and terminal. Maturin (pop. [1961] 53,445) is the state capital and chief trading centre. (L. We.)

**MONAGHAN** (Contae Mhuineachain) is one of the three counties of Ulster that are in the Republic of Ireland and forms an enclave of the Irish republic, projecting deeply into Northern Ireland. Area 498 sq mi. (excluding water); pop. (1961) 47,088. Most of the county boundary with its northern neighbours, Fermanagh, Tyrone and Armagh, winds through cultivated lowlands except on the Slieve Beagh, a desolate upland rising to 1,255 ft. For many miles the boundary with Tyrone runs along the Blackwater river, an affluent of the Bann.

Structurally, three main areas may be distinguished. The most northerly, Slieve Beagh, is characteristic of other Carboniferous plateaus of Ireland; the second, the Monaghan corridor, floored by Carboniferous beds, corresponds to many lowland areas of Ireland, at 200–400 ft. above sea level. It leads from the Erne valley to the Lough Neagh basin, and is used by roads, the railway from Clones to Armagh and the Ulster canal, which has been derelict for nearly 40 years. South of this corridor the third physical unit appears with a discernible edge; it consists mainly of Silurian slates and grits, though round Carrickmacross there is a basin floored by Triassic and Carboniferous beds. Generally about 500–600 ft. high, the Silurian hill country rises in long sweeping lines to more than 1,000 ft.

Despite the variety of rock formation, the whole landscape is made remarkably uniform by the presence of many hundreds of drumlins (whale-backed hills mostly 50–100 ft. high of varied length but in some cases as much as half a mile long). These drumlins give the lowland corridor of Monaghan a highly complicated drainage pattern, with an indeterminate divide between the waters of the Bann and the Erne. Characteristic also are numerous small lakes and peat flats, no doubt the relics of previous lakes and ponds for there is every sign that these waters are being reduced in size by sedimentation. In the Silurian hilly area similar drumlins and waters are found, varying from lakes of a few square miles to mere ponds and even peat flats.

Monaghan formed part of an ancient kingdom of Oriel which consisted of Monaghan, Louth and Armagh and was formed in A.D. 330 by three princes, descendants of Conn, who attacked Ulster. The Anglo-Norman advance broke up Oriel, but Monaghan remained dominated by the MacMahons and lay outside the main area of Anglo-Norman influence. In Tudor times the MacMahons tried to legalize their position by surrendering their land to the crown and receiving it back under English law. When Ross MacMahon, the reigning chief, fell foul of the government and was executed in 1559, a large area again came into the hands of the crown. Elizabeth I approved a settlement of Monaghan in 1591 by which the county was divided in estates between seven chief MacMahons and a McKenna. Monaghan was therefore not included in the later plantation of Ulster. With the establishment of the governments of the Irish Free State and Northern Ireland, a peculiarly large proportion of Monaghan's county boundary became interstate frontier.

The county council meets at Monaghan town and there is a county manager. Carrickmacross (*q.v.*), Castleblayney, Clones and Monaghan are urban districts. Ballybay is administered by town commissioners. The county sends three members to *dáil éireann*.

Agriculture in Monaghan is primarily of the northern type with small farms averaging 30 ac. and intensive cultivation; only one-eighth of the county's area is unimproved land. By tradition this is a flax-growing county, and beside streams the flax-retting troughs may be seen—though little flax has been grown since World War II. Grass, which is grown for seed, is sorted at Castleblayney. Little wheat is grown, but about one-sixth of the land is used for crops and one-sixth for hay. On many farms potatoes and oats are sold, and another main resource is cattle rearing, with dairying for the creameries.

Slightly over one-quarter of the population lives in towns and villages, which are mainly market centres at a distance of a few miles one from another. Boots and shoes are made in Castleblayney (pop. [1961] 2,127) and Carrickmacross (1,940). At Clones (2,107) there is a clothing works and an old-established factory making spades and shovels. Monaghan (4,013), the county town, has milling, bacon curing, furniture making and linen weaving. The main economic strength of these towns, however, lies mainly in their retail trade and monthly fairs. Carrickmacross lace is well known.

**MONAGHAN** (Muineachán), the county town of County Monaghan, N.Ire., is 55 mi. S.W. of Belfast by road and on the Ulster canal. Pop. (1961) 4,013. It is an agricultural market centre with a market hall dating from 1792. There is a 19th-century Roman Catholic cathedral of St. Macartan and a diocesan seminary (1½ mi. N.) for the diocese of Clogher. The early monastery founded there and plundered in the 9th and 10th centuries was in existence until 1161. A Franciscan friary founded on its site was suppressed by the English in the 16th century. James I incorporated Monaghan in 1613, when its residents were mostly retired soldiers from the English garrison. Charles Gavan Duffy, who became prime minister of Victoria, Austr., was born there, and Gen. Don Juan McKenna, the Chilean military leader, was born nearby.

**MONA ISLAND** is a limestone shelf of 20 sq mi. raised 150 to about 300 ft. out of the Mona channel about 50 mi. S.W. of Puerto Rico. The island has no permanent inhabitants. Guided missile installations and a lighthouse are maintained. There is a small landing strip. In spite of excellent beaches and good fishing, government attempts to develop the island as a tourist attraction had produced no results by the early 1960s. (T. G. Ms.)

**MONAL** (Monaul), any of the beautifully iridescent short-tailed pheasants of the genus *Lophophorus*, living 8,000 to 15,000 ft. up in the Himalayas from Afghanistan almost to Tibet. In the Impeyan pheasant (*L. impejanus*) the rooster-sized, crested male has a shining green and blue body, gilded purple neck, white rump and short red-brown tail. Related species are found in northern Burma and Yünnan and in southeastern Koko Nor and western Szechwan. *See* also Pheasant.

**MONARCHIANISM,** a theological term designating the view taken by those Christians who, within the church, toward the end of the 2nd century and during the 3rd, opposed the doctrine of an independent personal subsistence of the Logos, and affirmed the sole deity of God the Father. The representatives of the extreme monotheistic view, which, while regarding Christ as Redeemer, clung tenaciously to the numerical unity of the Deity, were called monarchians, a term brought into general use by Tertullian. It is usual to speak of two kinds of monarchianism—the dynamistic (or adoptionist) and the modalistic (or Sabellian)—though the distinction cannot be carried through without some straining of the texts.

By monarchians of the dynamistic class Christ was held to be a mere man, miraculously conceived indeed, but constituted the Son of God simply by the infinitely high degree in which he had been filled with Divine wisdom and power. This view was taught at Rome about the end of the 2nd century by Theodotus, who was excommunicated by Victor, and at a later date by Artemon, excommunicated by Zephyrinus. About the year 260 it was again propounded within the Church by Paul of Samosata (*q.v.*).

Modalistic monarchianism, conceiving that the whole fullness of the Godhead dwelt in Christ, took exception to the "subordinatianism" of some church writers, and maintained that the names Father and Son were only different designations of the same subject, the one God, who "with reference to the relations in which He had previously stood to the world is called the Father, but in reference to His appearance in humanity is called the Son." It was first taught, in the interests of the "monarchia" of God, by Praxeas, a confessor from Asia Minor in Rome about 190, and was opposed by Tertullian in his well-known controversial tract. The same view—the "patripassian" as it was also called, because it implied that God the Father had suffered on the

cross—obtained fresh support in Rome about 215 from certain disciples of Noetus of Smyrna, who received a modified support from Calixtus I. For the subsequent history of modalistic monarchianism *see* SABELLIANISM. *See* also ADOPTIONISM.

*See* A. Harnack, *History of Dogma*, vol. iii, pp. 1–118 (1897).

**MONARCHY,** strictly defined, means the undivided sovereignty or rule of a single person. The term is applied to states in which the supreme authority is vested in a single person, the monarch, who is the permanent head of the state. The word has, however, outlived this original meaning and is now used, when used at all, somewhat loosely of states ruled over by hereditary sovereigns, as distinct from republics with elected presidents; or for the "monarchical principle," as opposed to the republican principle. A distinction must first be drawn between elective and hereditary monarchies. Of the former class the most conspicuous was the Holy Roman empire, but in Europe all monarchies were, within certain limits, originally elective. After the introduction of Christianity, the essential condition of the assumption of sovereign power was not so much kinship with the reigning family as the consecration or "sacring" by the divine authority of the church. The purely hereditary principle was of comparatively late growth, the outcome of obvious convenience, exalted under the influence of various forces into a religious or quasi-religious dogma.

The old idea of monarchy, viz. that of the prince as representing within the limits of his dominions the monarchy of God over all things, culminated in the 17th century in the extreme version of the doctrine of the divine right of kings, and was defined in the famous dictum of Louis XIV: *L'état c'est moi!* The conception of monarchy was derived through Christianity from the theocracies of the eastern Mediterranean and of Rome, though Germanic tribal concepts of kingship were also incorporated into the medieval monarchy. The Greeks knew monarchy mainly in two forms, the Homeric and the Macedonian. In the first the king was a hereditary ruler whose authority was intimately bound up with his prowess in battle. In the second he was an imperial ruler who acquired divine properties, as in Hellenistic times his conquests, like Alexander's, took him farther away from the restraints of Greek rationalism and democracy into an oriental despotism.

Monarchy was the underlying principle of the medieval empire and also of the medieval papacy, the rule of the popes during the period of its greatest development being sometimes called "the papal monarchy." As the unity of medieval Christendom broke up, monarchy acquired a new basis. The monarch was ideally placed to provide the centralized power needed by the new nation states of the 16th and 17th centuries. Frequently he became an absolute ruler, the only source of law, the only mainspring of administration. Sweden and Poland, among continental European states, maintained checks on royal absolutism. But in England, Tudor absolutism retained parliamentary institutions, so that when the Stuarts endeavoured to assert the divine right of kingship they were frustrated by forces that were determined to set limits to monarchical power. The execution of Charles I (1649) and the revolution against James II (1688) were decisive blows against monarchical absolutism. By the Bill of Rights of 1689 it was established that the king reigned not by divine right but solely with and by the consent of parliament. To this the Act of Settlement of 1701 laid down that the crown's ministers should be "responsible" for the acts of the sovereign. By this the essential basis was laid for a "constitutional" or "limited" monarchy, though the full working out of the principle took more than a century to effect. After 1717 the king ceased to attend cabinet meetings and gradually the office of prime minister (*q.v.*) evolved. With the passage of the Reform act, 1832, actual sovereignty was recognized to lie in the people as represented in parliament and the functions of the British monarch began to assume their modern form.

On the continent of Europe monarchical absolutism in general continued to thrive in the 18th century, accommodating itself even to the first impact of the "enlightenment" in the form of the "benevolent despot," of whom Frederick the Great of Prussia and Catherine the Great of Russia were notable examples. In 1789, however, the French Revolution dealt it a blow in some respects more shattering than it had sustained in Britain. Even when, as in many countries, the institution survived or when, as in others, it was restored in the reaction after the Napoleonic Wars, it was almost always in a modified form. The monarch accepted constitutional limitations on his power, abandoned his taxing and law-making functions to a representative legislature and devolved his executive powers, in varying degrees, on to ministers who ruled with the consent of parliament. In France, despite successive attempts, the monarchy failed to re-establish itself. In Latin America republics rose on the ruins of the Spanish and Portuguese empires; Brazil was unique in retaining a monarchy down to 1889.

World War I brought ruin to those monarchs who had retained so much personal power that they could not escape blame for defeat or social injustice. Among such victims were the monarchies of Russia, Germany and Austria-Hungary. In Spain the monarchy was overthrown in 1931 though the constitution of 1947 still called Spain "a kingdom," even while proclaiming General Franco as chief of state. World War II dealt further blows at monarchy, not only in Europe (*e.g.*, Italy) but also in the far east. In China the Manchu dynasty had been overthrown as lately as 1912. In Japan defeat produced a voluntary abandonment of the doctrine of imperial divinity; by the constitution of 1946 (adopted 1947) the emperor became merely "the symbol of the state and of the unity of the people." Elsewhere the continuing support of western powers, combined sometimes with a policy of wise concession to popular demands, often enabled monarchical rulers to maintain themselves. This was so in Thailand, Iran, the Hashemite kingdom of Jordan, Saudi Arabia and also in the African states of Ethiopia, Libya and Morocco.

In Europe monarchy survived in Britain, Norway, Sweden, Denmark, Belgium, the Netherlands and Greece. Of these, Denmark was the last to abandon absolutism (in 1849), but all the Scandinavian monarchies were notable for their scrupulous constitutionalism and their democratic unpretentiousness. The pattern of all these limited monarchies was set by Britain, a process in which the personal prestige and longevity of Queen Victoria played an important part.

The British monarch of the 20th century is the legal head of the state but the acts done in his or her name are in fact those of ministers responsible to parliament. The monarch is above party and outside politics. The only discretionary powers of the monarch are to choose a prime minister (and normally the clear working of a two-party system makes the selection automatic) and conceivably to refuse a dissolution of parliament. In relation to ministers the monarch has, in Walter Bagehot's words, "the right to be consulted, the right to encourage, the right to warn"; the monarch must never so act as to come into conflict with the people's elected representatives. As a symbol of national unity, a focus for loyalty and an embodiment of accepted standards, the monarch has great influence, intangible admittedly but also pervasive. The British monarchy has also a special role in relation to the commonwealth, where the fully self-governing countries all recognize the monarch as head of the commonwealth.

**MONASTERBOICE** (MAINISTIR BHUITHE, *i.e.*, "monastery of Buite"), the ruins of an ancient monastic settlement founded by Buite or Boethius (d. 521), which lie 5 mi. N. of Drogheda in County Louth, Republic of Ireland. The relics date from the 8th to the 12th century and comprise two churches, a round tower, three sculptured crosses, two simple tombstones and a sundial. The "South" and older church (c. 9th century) has both nave and chancel; the other is rectangular. The round tower, though incomplete at 110 ft., is one of the highest in Ireland. The crosses, sculpted in elaborate detail, are outstanding in magnitude, design and execution. The North cross is 18 ft. high, the High or West cross 21 ft. and Muiredach's cross is 17 ft. and monolithic.

**MONASTERY,** the home of a religious community (*see* MONASTICISM). The word is commonly used only of houses of men, but in what follows houses of women religious, widely though not properly known as convents, will also be considered; a monastery ruled by an abbot is called an abbey.

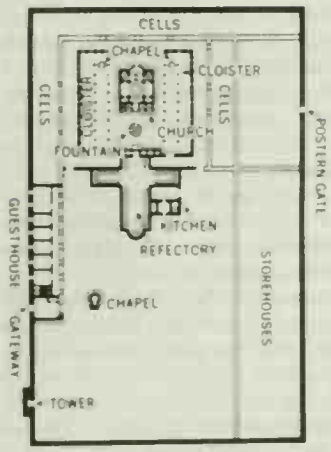

FIG. 1.—MONASTERY OF THE LAURA, MT. ATHOS, GREECE, FOUNDED IN 963

The earliest Christian monastic communities inhabited groups of cells or huts collected about a common centre, which was usually the abode of some anchorite celebrated for superior holiness. Such, for example, was the case with the disciples of Anthony in the Egyptian Thebaid in the early 4th century. The monastery properly so-called came into existence a few years later when Pachomius, also in Egypt, established the cenobitic life, which rapidly spread to Syria and elsewhere. The Pachomian monks lived in separate huts, forming a religious hamlet. They had no refectory but ate their common meal reclining on strewn grass, often out-of-doors. By degrees order was introduced in the groups of huts, and they were arranged in lines like the tents in an encampment or the houses in a street. From this arrangement a line of single cells came to be known by the Greek word *laura* (*q.v.*), meaning "lane" or "passage."

The necessity for defense from hostile attacks, economy of space and convenience of access from one part of the community to another by degrees dictated a more compact and orderly arrangement of the buildings of a monastic cenobium. Large piles of buildings were erected, with strong outside walls, within which all the necessary edifices were ranged round one or more open courts, often surrounded by cloisters, though very often also the buildings stood free inside the enclosure, with an ambulatory or colonnade running along the inner side of the wall. No fixed plan was adopted, but a usual eastern arrangement may be seen in the plan of the Laura, on Mt. Athos in Greece (fig. 1).

When monasticism was introduced to the west, its local habitation took various forms in harmony with the social conditions and situation of the community. Thus Celtic monachism preferred a group of cells and small houses built of stones, such as may be seen on various sites in Ireland or in the excavations at Iona (Scot.) or Whitby (Yorkshire). In Latin lands the buildings were larger and more compact, but the site was often such as to make elaborate or regular planning difficult, as for instance in the upper monastery of Subiaco or that of Cava de' Tirreni northwest of Salerno in Italy.

Monasticism in western Europe, as is well known, was progressively influenced by the rule of St. Benedict of Nursia, which was composed about A.D. 535–540 but was not widely followed before the end of the 7th century. Benedict in his early life had been familiar with the small, simple and almost casual buildings of the monasteries in the valleys and mountains of central Italy, and the home of his later life, where he wrote his rule, was the rugged hilltop of Monte Cassino. In the rule there is mention of an oratory, refectory, cells for monks and novices and quarters for guests; it is also laid down that all things necessary for the life of the monks should be contained within the enclosure, and water, a mill, a bakehouse and offices for all necessary crafts are specified, while the mention of a porter implies a wall and a single public entrance. No indication, however, is given of the size of the buildings or of their relation to each other, and there is also no mention of a cloister.

The cloister, soon to become the central feature of the monastic complex and used in some languages as a synonym for the whole monastery (as in Fr. *cloître* and Ger. *Kloster*), originated in northern Italy and was probably derived not, as was once suggested, from the court (atrium) of Roman domestic buildings but from the narthex (*q.v.*) or porticoed court at the west end of early basilical churches such as can still be seen at Sant'Ambrogio in Milan. When once this had been transferred to a position alongside the nave, with its eastern walk abutting on the transept of a cruciform church, it became the circulating area and the living

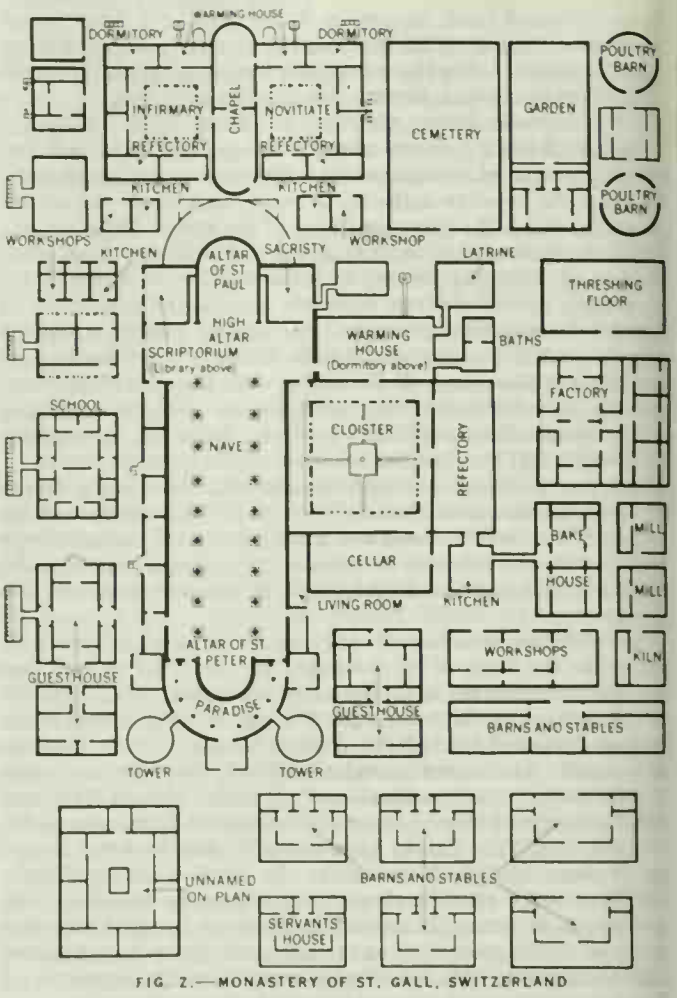

FIG. 2.—MONASTERY OF ST. GALL, SWITZERLAND

room of the whole establishment, with ranges of buildings on the three vacant sides: to the east the dormitory, novitiate, warming house and latrines; to the south, farthest from the church, refectory and kitchens; to the west, storerooms and guest rooms, adjacent to the one exit to the outer court. This, the classical layout, is seen in almost all its essentials, and with all possible additions and elaborations needed in what was to be a kind of religious civic centre or county town, in the interesting document known as the plan of St. Gall (Switzerland) which was in fact almost certainly the "blueprint" of a model monastery circulated

by Benedict of Aniane when he was acting as principal monastic reformer to the emperor Louis the Pious about 820. The buildings, with some exceptions, seem to have been of one story only, and possibly many of them were wooden.

Not all Benedictine abbeys, not even the greatest, had in practice all the appurtenances of the St. Gall plan, but almost all had, in one form or another, the four-sided cloister surrounded by the conventual buildings. In these only two significant changes had been made in the centuries between Charlemagne and the religious revival of the 11th century. The first was the addition of an assembly room (the chapter house) as an imposing architectural feature in the east range of buildings near the church; the second, perhaps not unconnected with this, was the lifting of the dormitory (dorter) to first floor (U.S. second story) level, with the consequent increase of available space below it on the ground floor. Of the four walks of the cloister the quietest, that alongside the nave of the church, was used as the place for daily work and study. Whereas south of the Alps the cloister was normally sited north of the church to secure a maximum of shade and steady light, north of the Alps the need for a maximum of light and warmth led to its transference to the south; where, however (as in England at Canterbury, Bury St. Edmunds and Gloucester), the ground to the south of the church was already occupied by churches or a graveyard, the planners had no hesitation in siting the cloister to the north.

In all monasteries the church, constructed on a scale that often had little apparent relation to the number of potential worshipers, was the principal architectural feature, and the multiplication of liturgical processions, of private Masses and often of popular shrines helped to lengthen the nave and multiply side chapels. In addition, the church, whenever the architect had a free hand, occupied the highest point of the site.

Round the cloister lay the sacristy, chapter house, treasury, novitiate and warming house, over which extended at first floor level the dorter, with "night" stairs giving direct access to the transept of the church and "day" stairs debouching in the cloister. At the end of the dorter and usually at right angles to it lay the rere-dorter or *necessarium* (latrines), a building of some size standing over the great drain. Along the south walk lay the refectory (frater), with the kitchen at its southwest angle outside the cloister range. To the west lay the cellarage and the cellarer's office with rooms for distinguished guests and (later) the abbot's chambers at first floor level.

Outside this nucleus lay two other blocks of buildings. To the southeast—that is, in the most secluded position—lay the infirmary, a monastery *in parvo* with a large hall containing beds, chapel, frater and often a small cloister and garden; to the west of the cloister lay an extension of the original (early) guest quarters. Beyond these, to the west of the cloister and church, lay the great court, bounded by a precinct wall, entered by a great gateway, and bordered by offices and stabling of every kind. It must be remembered that Benedictine abbeys were often ancient foundations in cities or on an eminence (*e.g.*, Sulzburg, Monte Cassino, Durham and Worcester) where the normal plan encountered hindrances, and radical modifications were often necessary.

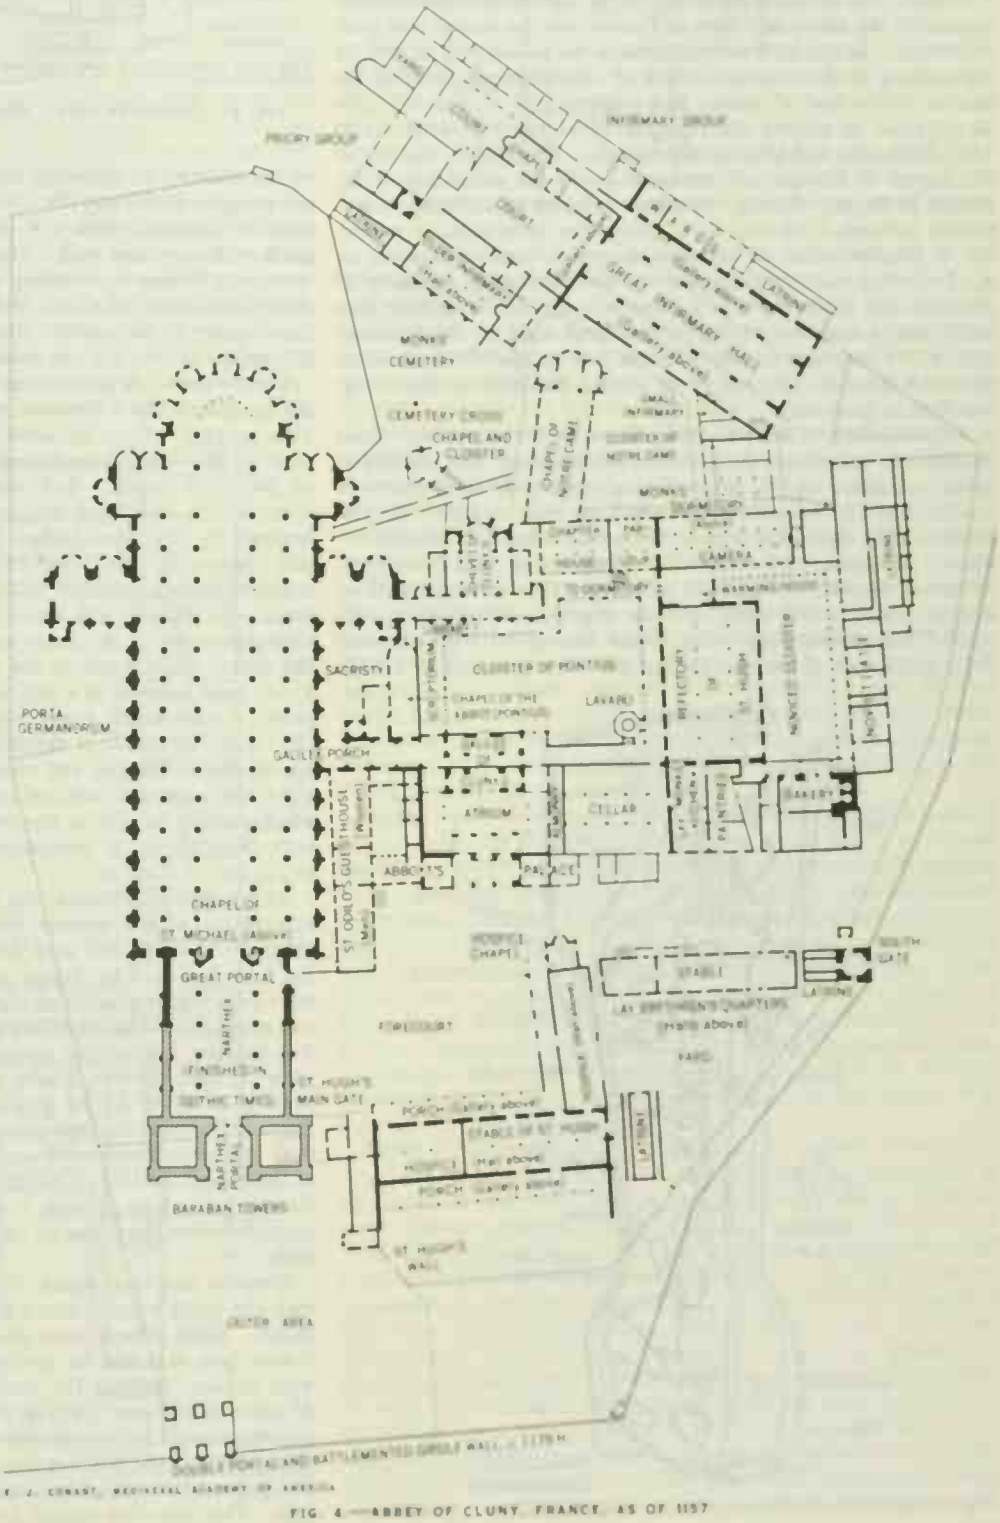

FIG. 4.—ABBEY OF CLUNY, FRANCE, AS OF 1157

It was not till the 14th century that a large room for books became common. Before that date, provision was made for books in presses against the wall of the cloister, and in particular against the wall adjoining the church, which, in a normal plan, would be the lightest. In Cistercian abbeys there was from the beginning a small book cupboard between the church and the chapter house. Writing and illumination were done either in the north walk of the cloister, where in the later centuries of the middle ages small studies or "carrels" were provided for individuals (as at Gloucester), or in a special room in or adjacent to the warming house (calefactory). (*See* LIBRARY: *History: Middle Ages and Renaissance.*)

**Cluny.**—Of all the monasteries of the west in the "Benedictine centuries" the abbey of Cluny in France was the largest and most celebrated. In the 12th century it housed a community of 400, to say nothing of the constant stream of Cluniac monks visiting the mother abbey and of guests and pilgrims, yet it was still able on occasion to receive the papal or royal court or even, as in 1245, both pope and king simultaneously. The church was by far the largest in Europe and remained so till the rebuilding of St. Peter's in Rome. Almost the whole complex of buildings disappeared between 1789 and 1814, during the revolutionary period, but a lengthy series of excavations, which were conducted by K. J. Conant under the auspices of the Mediaeval Academy of America, has made possible a reconstruction of the ground plan with some conception of the architectural style of the buildings (fig. 4). Cluny and its dependencies had no specific features of plan and differed from houses of similar size only in their magnificence of decoration.

**Augustinian Canons and Premonstratensians.**—These monasteries resembled those of the Benedictines, but the largest house of canons was no larger than a moderately sized abbey of monks, and the majority were small or even minute. As the canons rarely manned a cathedral (Carlisle is the only English instance) or a great city church (St. Mary Overy, now Southwark cathedral, London, is hardly an exception) they often planned on a small scale; if and when funds or numbers demanded or permitted enlargement they often found themselves without room for a south aisle of the church, the site being occupied by a walk

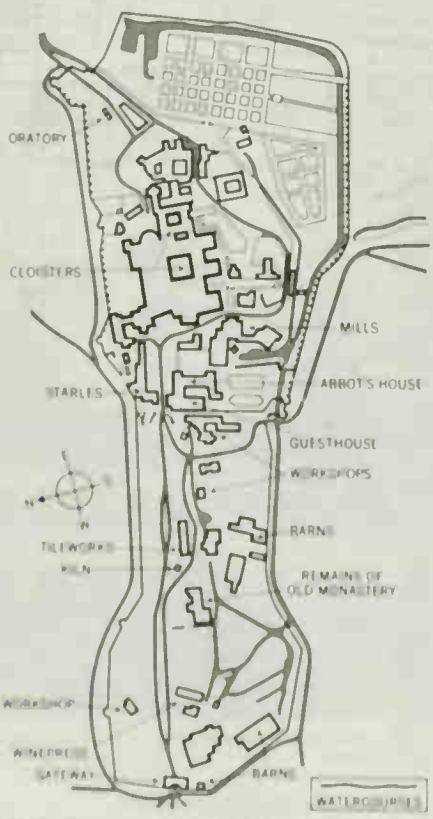

FIG. 5.—ABBEY OF CLAIRVAUX, FRANCE, FOUNDED IN 1115 (CISTERCIAN)

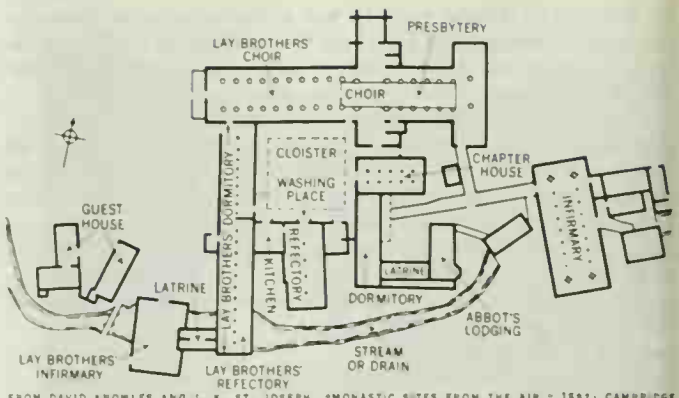

FROM DAVID KNOWLES AND J. K. ST. JOSEPH, "MONASTIC SITES FROM THE AIR," 1952; CAMBRIDGE UNIVERSITY PRESS

FIG. 6.—FOUNTAINS ABBEY, YORKSHIRE, ENGLAND, FOUNDED IN 1132

of the cloister, or forced to dislocate the buildings of the eastern range to make way for an enlarged transept. They also frequently dispensed with the western range, closing the cloister garth with a curtain wall. The Premonstratensians in particular were very flexible in planning, and even their larger houses show great irregularity of siting, and displacements from the conventional order in the various apartments and slightly rhomboid or trapezoid cloisters are not unknown.

**Cistercians.**—A new era in planning and building began with the spread of the Cistercian order in the early decades of the 12th century. Four circumstances, out of the many new features of the order, helped to distinguish their abbeys from those of the older monks: they were constructed rapidly on virgin sites, with a free hand for planning; uniformity of layout was imposed by their constitutions; simplicity of style and decoration was likewise imposed; and provision had to be made for large numbers of lay brothers within the monastic enclosure. Their architects, within these limits, were further bound by two considerations, one of sentiment and one of utility: the high altar of the church must stand on the highest point of the site, and provision must be made of a copious supply of water for sanitary purposes, a need which sometimes necessitated a northern site for the cloister to permit of drainage in that direction. Generally the apartments on the east and south range lay in the traditional positions, but when a Cistercian community increased greatly and it was necessary to enlarge the refectory lack of space in the south walk often led to the construction of a new frater at right angles to the line of cloister.

As for the lay brothers, the Cistercians solved the problem by making use of the western range, largely otiose in Benedictine abbeys. This was still used for cellarage at ground level, but on the first floor a long dorter accommodated the brothers, while their refectory was sited on the ground floor of the range, which was extended to the south beyond the angle of the cloister garth. The kitchen, common to monks and brothers, was placed at the angle between the two fraters. The lay brothers had also an infirmary on a site to the southwest of the cloister. There were thus to all intents two monasteries in a single complex. For worship, the lay brothers used some of the western bays of the nave of the church, and often, to protect the monks in the cloister from disturbance, a long passage, known as the lane, within the western range led from the frater to the church, with a door into the nave aisle.

Mention has been made of the drainage; this, closely linked with the water supply, was a matter in which the Cistercians excelled. Their abbeys were always sited where a swiftly flowing stream ran, or could be conducted, through the buildings from west to east, flushing the drains and carrying away the refuse. At some monasteries, such as Fountains in Yorkshire (fig. 6), the engineering and architectural devices are both ingenious and beautiful. Besides the flow for drainage, an entirely independent supply was available for drinking and washing throughout the buildings. This was often carried from a spring, at a distance from the

abbey, by stone conduits or lead piping, and distributed round the cloisters where needed.

The uniformity of Cistercian planning strikes the most casual observer. While the materials used show great local differences, as may be seen, for example, by comparing Fountains and Rievaulx (Yorkshire) with Furness (Lancashire) or Dundrennan (Kirkcudbrightshire), the plans are almost identical, and it is only in a few small abbeys that never flourished in numbers and wealth, such as Kymmer in Wales, that the primitive simplicity of the earliest buildings was never given full development.

**Carthusians.**—This religious order, which was in origin eremitical, always retained its character, though it domesticated the hermit's life to the extent of placing his cell within an architectural complex. The cloister garth, which was often of considerable size, was surrounded by the miniature houses of the brethren, each with its small garden plot. The church, often no more than a fair-sized chapel, adjoined the cloister on the side where the one means of egress led to the refectory, the prior's cell, the guesthouse and the outer gate. In early Charterhouses (the English corruption of the original Grande Chartreuse) the lay brothers lived in a group of buildings at some distance from the monks' cloister (*e.g.*, at Witham and Hinton in Somerset), but later, when urban Charterhouses became common, they were accommodated (as at the London Charterhouse) within the monastic enclosure. Normally, and in England universally, the buildings of a Charterhouse were modest, not to say mean, in size and in appearance (*cf.* the church and buildings at Mount Grace in Yorkshire), but on the continent of Europe (*e.g.*, at Florence and Pavia) they were constructed on a scale with materials of great magnificence. Thus, however, made no alteration to the solitude and simplicity of the individual Carthusian. (See also CHARTREUSE, LA GRANDE.)

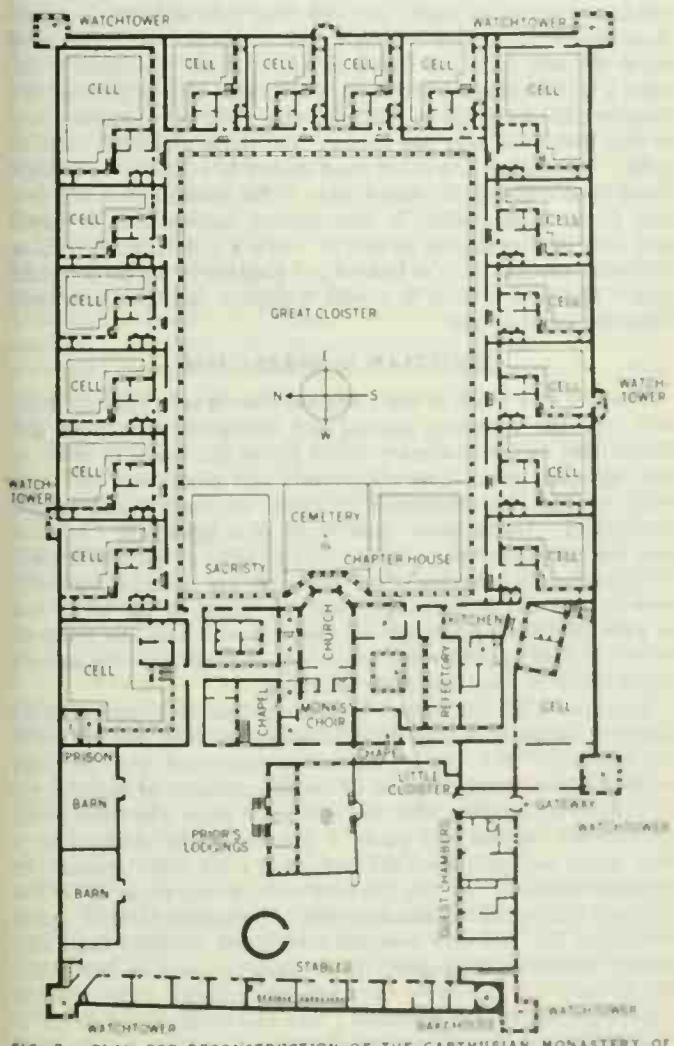

FIG. 7.—PLAN FOR RECONSTRUCTION OF THE CARTHUSIAN MONASTERY OF PORT STE. MARIE, NEAR CLERMONT-FERRAND, FRANCE, FOUNDED IN ITS ORIGINAL STATE IN 1219

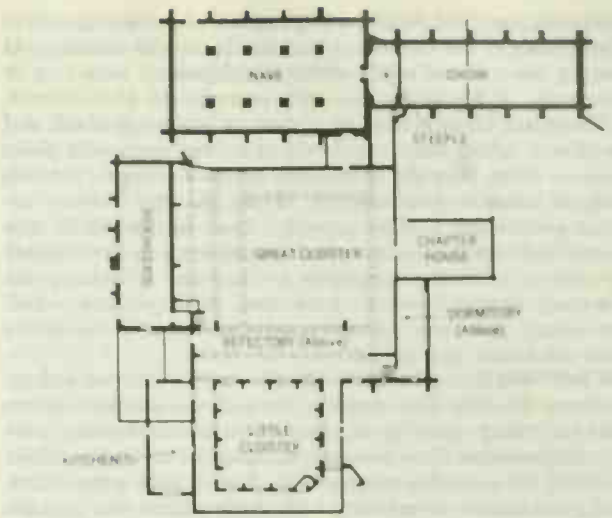

FIG. 8.—FRANCISCAN FRIARY, WALSINGHAM, ENGLAND, FOUNDED IN 1347

**Mendicant Friars.**—The orders of friars, poor by definition in the first century of their appearance, settled generally in towns in humble tenements given or lent to them by benefactors or the civic authorities. As time went on they, or their friends for them, constructed a permanent friary with a large church and the normal common rooms such as refectory and chapter room, but these were always on a small scale save at the most important houses in London and such academic houses of study as Oxford and Cambridge. This article is not concerned with the peculiarities of their church architecture. Access to the small cloister was customarily by means of a transit across the church, and the cloister was usually merely a corridor within the walls of the domestic buildings. As the sites of friaries were often valuable, the buildings disappeared rapidly at the dissolution of the monasteries in England, but exception must be made of a few friaries, especially of the Franciscans and Carmelites, which were situated in the open country. These followed, with some modifications, the normal plan of the small monastic house. The only large room, not found in monastic houses, was the school for lectures to the young members of the order.

**Nuns.**—The monasteries of women usually followed, on a smaller scale, the type of plan favoured by the men's branch of the order, though as the Cistercian nuns had no need to provide for lay brothers their houses showed none of the features peculiar to the White Monks. The Gilbertine order in England, which was one of nuns directed by a small group of canons, is an exception to this general rule. There the plan took the form of two similar monasteries, a greater (that of the nuns) and a less, separated by a church divided by a medial wall and accommodating both nuns and canons, all of whom had a view of the common high altar. An example of a large Gilbertine house can be seen at Watton, Yorkshire, where the whole plan was brought to light by Sir William H. St. John Hope in 1893–98.

**Later Developments.**—As the centuries passed, considerable modifications were made in the monastic buildings, almost all in the direction of greater comfort and individual privacy. Some of these changes reflected changing social conditions, while others were due to relaxation of the rule within the houses concerned. Chief among them was an increase in size and amenity in the accommodation provided for the abbot or prior. Originally merely a cell either in the western range (Benedictine) or near the dorter (Cistercian), it grew into a substantial house, with dining hall, oratory and guest rooms either near the infirmary (Cistercian) or west of the cloister (Benedictine). In the later centuries of the middle ages these houses were probably the most fully developed specimens of domestic architecture and planning in existence, with comfortable rooms, heated by fires of coal and provided with facilities for washing, including piped water at first floor level.

A similar tendency led to the multiplication of private chambers for the officials of the monastery and for doctors of theology, as well as for the sick and aged. Other developments were seen in the gatehouse, which in the late 14th century was often rebuilt, as at Thornton, Lincolnshire, on a scale of great splendour, and in the library, which came into being as a large room with desks and presses either over the north walk of the cloister or between the chapter house and the church. From the 16th century onward the private cell became general. Even in the middle ages the monks had come to occupy a wainscoted study or carrel either in the cloister or in the dorter, as at Durham. Gradually the cubicle study became common; this in time developed into a small private room, and only the reformed Cistercians retained the common workroom and dorter.

**Post-Reformation Changes.**—In the various reforms and revivals from the late 16th century onward the religious orders adopted the ruling styles in architecture, in which churches were sharply distinguished from domestic buildings of all kinds. These latter, in all the countries influenced by Renaissance architecture, became great masses of masonry with many stories and multiple fenestration arranged around a succession of quadrangles. Ecclesiastical institutions were indistinguishable from secular or private buildings of comparable size, and in almost every country such monasteries as remained in existence were clothed with thick layers of new buildings within which some of the old cloisters and rooms were embedded. Thus Citeaux, Monte Cassino, Einsiedeln and the abbeys in the valley of the Danube (to name but a few) became monuments of Louis XIV or baroque architecture and the traditional monastic plan was submerged or ignored. The library grew in size and became a splendid apartment, seen at its fullest development in northern Italy, Bavaria and Austria.

In the course of the revival of monastic life that began in France in the middle of the 19th century, spread gradually throughout Europe and later extended to North America and elsewhere, a great variety was seen in the design and planning of monasteries. All save the Carthusians and reformed Cistercians have been affected by the substitution of corridors of private rooms or cells for the public dormitory. Even in the case of the Cistercians the medieval layout had been so thoroughly overlaid that after the destruction at the time of the French Revolution the primitive plan fell into oblivion and the monasteries of the Trappists bear little resemblance to the medieval abbeys of the White Monks.

Similarly, Benedictine abbeys such as Solesmes in France were built with several stories of cells opening upon galleries and staircases, with the cloister merely a wide vaulted passage on the ground floor. Though the cloister and cloister garth have been usually retained, they now serve simply as a walking place; the cloister has lost its functional importance in the plan and is often covered by buildings; the dormitory has ceased to exist as an architectural feature, the library has continued to be an outstanding member of the plan and other buildings containing classrooms or lecture rooms and accommodation for pupils or students adjoin or surround the monastic nucleus of the complex. Such an establishment as for instance Ampleforth abbey in Yorkshire, which has the largest monastic community and houses the largest Roman Catholic boarding school in England, has developed in detached buildings on a sloping site and might well be taken from a distance to be simply a large educational or training establishment.

Other monasteries, both in Europe and America, such as St. Vincent's archabbey, Latrobe, Pa., or St. Meinrad's, St. Meinrad, Ind., show to the outer world lofty windowed façades that have nothing in them of the traditional monastic design. Few, even of modern Cistercian abbeys, have the simplicity of plan of those of the 12th century, and an abbey in full life and vigour, such as Gethsemani, Ky., lies at the centre of offices and outbuildings that have disappeared from most medieval sites.

In the 19th and 20th centuries there were some reversions to medieval design. Architects and antiquaries such as Viollet-le-Duc in France and Sir William H. St. John Hope in England restored by research and excavation the primitive plans of the various orders, and where a monastery was built on a virgin site care sometimes was taken to preserve much of the traditional plan. Speaking generally, however, the modern Benedictine monastery, however impressive in size and in the extent of its satellite buildings, has little resemblance to its medieval predecessor save in the presence of a large church (often, architecturally speaking, a large chapel without transepts or aisles) and of an adjacent cloistered walk.

At the same time, the preservation and study of the abandoned or ruined abbeys of earlier times have made great advances in the British Isles and in France, and monastic sites are visited yearly by many thousands. In Great Britain the ministry of works has rescued numerous monastic ruins from neglect or destruction and has surrounded them with a décor of green turf and taken every care to arrest further deterioration.

BIBLIOGRAPHY.—There is no authoritative general work. For Cistercian architecture M. Aubert, *Architecture cistercienne en France* (1947), is definitive, and on a smaller scale A. R. Martin, *Franciscan Architecture in England* (1937). K. J. Conant, *Carolingian and Romanesque Architecture, 800 to 1200* (1959) contains much on Cluniac arrangements. For a general sketch *see* also D. Knowles and K. St. Joseph, *Monastic Sites From the Air* (1952). (M. D. K.)

**MONASTICISM** (MONACHISM), the system of life led in a religious community withdrawn from the world. Both the monastic way of life and the organization of institutions to promote such a way of life long precede Christianity and, in the east, where India has been particularly influential, developed independently of it. Monasticism may be defined as a renunciation of sexual pleasure, the ties of family life and most normal human occupations in order to devote oneself to the things of God. The word itself, derived from the Greek *monos* ("alone"), originally implied a withdrawal into seclusion, but it came also to denote both membership of a group of solitaries whose life was corporate only in that they lived near one another, and those who lived communally. The motive of a monk must always be religious, or at least based upon a highly developed sense of the potentialities and destiny of the human soul; in consequence, monasticism is found only in a mature society or one in which a fully mature religion has been preached, such as Ireland and England in the early middle ages. This article deals first with Christian and then with non-Christian monasticism.

## CHRISTIAN MONASTICISM

The aim of a monk in the Christian church is to separate himself from the unethical, sensual and irreligious attractions and distractions of the customary social life of the world in order to free his spirit from those allurements and hindrances that normally prevent the attainment of moral self-control and mental tranquillity. In the peace thus found or achieved the Christian may further endeavour to fit himself for union of spirit with God. In Christian monasticism three elements are at least implicitly present: the ascetic separation from the things of the world and in particular from marriage and the domestic life; the religious service of God by prayer and adoration; and the desire for an ever closer union of mind and heart with God.

Into such a life the gospel "counsels" of poverty, perfect chastity and obedience to a spiritual authority could be inserted without difficulty. Nor was it long before experience, and the basic social relations implied by the Christian command of neighbourly love, made it clear that while the number of those who could profit by absolute solitude was small, a communal life, directed by a wise leader and with fixed practices, had a far wider appeal. In cenobitic monastic life the physical solitude was replaced by the spiritual solitude of the abandonment of possessions and of family and social life, and very soon the term monk included (and ultimately primarily designated) those living a common life, while the solitary was known by the name of anchorite ("one who retires or withdraws") or of hermit ("one who dwells in the desert").

In the course of centuries the meaning of the term was widened still further, and at the present day the French derivative *moine* is applied to friars as well as to the monastic orders; but in tech-

nical ecclesiastical language "monk" is restricted to those bound by the vows of religion and belonging to an order whose members are physically separated from the world by life in a monastery within the bounds of which they spend their days, whether their family be quasi-eremitical or with the full common life. In this monastery they live under a rule and the government of a superior to whom they are bound by vow. (For the orders of friars, *see* MENDICANT and the articles referred to there.)

It may be added that from the earliest times the vocal adoration of God was recognized as an integral part of a monk's life and that the communal performance of the liturgy known as the divine office (*see* HOURS, CANONICAL) is a necessary ingredient of the fully monastic life. Of itself, therefore, the monastic life is a contemplative one, though here again in the course of centuries such active duties as teaching and preaching have come to be part of the employment of several monastic institutes. In the early middle ages the task of intercession for the rest of Christendom was looked upon as belonging to the monastic order, but this is not peculiarly part of the monastic life, save insofar as all Christians pray and work for others, in their various measures and ways.

(M. D. K.)

### EASTERN MONASTICISM

The ground was prepared for Christian monasticism in both Jewish and pagan culture. The monks looked back to Elijah, Elisha and St. John the Baptist as their prototypes. In the century before and after the birth of Christ, there were the Essenes and the community, perhaps Essene, whose "monastery" has been excavated at Qumran in connection with the Dead sea scrolls (*q.v.*). Christians of the 4th century thought they recognized the earliest Christian monks in the 1st-century Jewish community of Therapeutae described by Philo in the *De vita contemplativa*. (*See* JEWISH SECTS DURING THE SECOND COMMONWEALTH: *Ascetic Sects.*) Many elements of thought, language and practice current in contemporary Greek philosophy (Pythagorean, Neoplatonist, Stoic or Cynic) and in hellenized Egyptian religion were ready to be developed in a Christian sense. And the ways of Indian religion were not completely unknown.

Jerome's story of Paul of Thebes is of doubtful historicity, but its picture of anchorites withdrawing into the deserts from persecution in the 3rd century probably represents a true tradition. (*See* PAUL, SAINT, of Thebes.) With the conversion of Constantine I (*c.* 312), Christian monasticism, hitherto embryonic, developed up and down the Roman empire, as an attempt to retain the full rigour of the gospel in a world wherein nominal Christianity was at a premium.

**Egypt.**—Egypt was the first centre of the monastic movement. St. Anthony (*q.v.*) of Egypt was the pioneer of desert monasticism. After many years of solitary spiritual conflict in or near the Nile valley, he was joined by other solitaries on the edge of the Arabian desert east of the Nile in middle Egypt (*c.* 305). When Christian persecution ceased after the so-called Edict of Milan, he moved (313) across to his "interior mountain" near the Red sea, where he stayed till his death (a Coptic monastery still survives there), paying frequent visits to his "outer monastery," where high and low came to consult him. His life, written by St. Athanasius and early translated into many languages, is a spiritual classic. The pattern established by him was further developed in the monastic settlements of Nitria and Scete (Scetis), both founded well before his death, in the region west of the Nile delta—a group of solitary cells attached to a church centre where the monks would assemble on Saturdays and Sundays for worship and a common meal. This came in Palestine to be called a laura (*q.v.*).

Very soon men were flowing out by the thousands to these deserts. Most of them were unlettered Egyptians, but there was a sprinkling of highly educated men from many lands, among them Evagrius Ponticus (*q.v.*), whose writings played a formative role in subsequent monastic language and thought. Palladius, whose Lausiac history (written *c.* 420) gives the first general survey of the monastic world, had been Evagrius Ponticus' disciple in the Cells near Nitria. And Johannes Cassianus, who was in Egypt at much the same period, was also deeply indebted to Evagrius.

The interior desert of Scete (the Wadi en Natrun, where four Coptic monasteries still survive) provided the core of the great collection of *Apophthegmata patrum*, which was growing up from the middle of the 3th until at least the 7th century. It provides a priceless corpus of "case law" of the ascetic and spiritual life, wherein the sober wisdom and charity of the "old men of the desert" take into their ken all that is human.

Cenobitic (conventual; from *koenobion*, "life led in community") monasticism was first organized in upper Egypt by St. Pachomius (*q.v.*), whose monastic rule is the earliest extant. His monks, named Tabennesiotes after his great monastery near Dandarah, formed a single community distributed in a number of monasteries, all owing obedience to one head. Each monastery was enclosed within a wall and contained a church and a refectory, where the monks assembled daily for worship and food, and a number of houses into which they were distributed according to their occupation. The monks did not pass on from the cenobitic life to that of the solitary. By the end of the 4th century the community numbered about 5,000 and extended as far as Canopus near Alexandria. Neither Anthony nor Pachomius was ordained. Monasticism was primarily a lay movement, as it remains in the Eastern Church to this day.

**Mesopotamia and Syria.**—Elsewhere in the Roman empire and beyond, for example in Mesopotamia, monasticism developed independently but increasingly under Egyptian influence. In northern Syria the ideal of the solitary tended to fantastic expression, as in the pillar saints, or Stylites, of whom St. Simeon Stylites is the supreme example—committed to his pillar top after the pattern of his Lord nailed to the cross.

**Palestine.**—The really formative influence, after Egypt, is to be sought in Palestine, where a highly international monasticism was already developing in the 4th century. Mention must be made of the western pilgrims, Jerome and his ladies at Bethlehem, Rufinus and the two Melanias on the Mount of Olives. But the key figures are St. Euthymius (378–473) and his follower St. Saba (439–532), who "made a city of the wilderness" of Judaea, peopling its hilltops and its gorges with countless monasteries and hermits. The works of Cyril of Scythopolis (fl. *c.* 550), himself a monk of the wilderness, relate their story. In Greek hymns in honour of the ascetics, Euthymius and Saba are put second only to St. Anthony. For they are the founders of the Eastern Orthodox monasticism, which persisted when Egypt and Syria had largely gone aside into heresy.

To this Judaean monasticism Egypt, Syria and Asia Minor were all contributory. The cenobitic life was subordinated to the eremitic in a single system, of which the focus was the laura, to which monks graduated from the *coenobium*, now little more than a novitiate, while monks of the laura aspired to pass on in due course, permanently or for long periods, to the more absolute solitude of the utter desert or of walled-in cells or inaccessible caves closer to the laura. The greatest of these monasteries, the laura of St. Saba (Mar Saba) on the side of the Cedron gorge, has an unbroken history from his first settling in a cave there in 478 down to the present day. For centuries it continued to play a creative part in the development of the hymnology and the monastic office of the Eastern Church.

Alongside St. Saba in the fight for Chalcedonian orthodoxy stood St. Theodosius (d. 529), whose great hilltop *coenobium* below Bethlehem was more of the Basilian type (*see* below, *Byzantine Empire and Modern Greece*). From it later in the 6th century came John Moschus, author of the "Spiritual Meadow," which gives for the end of the period before the Islamic conquest the same kind of picture that Palladius gave for the 4th century; and his companion, St. Sophronius, whose life of St. Mary of Egypt sums up much of the spirituality of the same period. Sophronius, as patriarch of Jerusalem, had the task of surrendering the Holy City to the caliph Omar.

**Sinai.**—In the Sinai peninsula monasticism flourished from the 4th century, but more particularly from the construction by Justinian I of a fort that became the hub of monastic life in the peninsula and still exists as the monastery of St. Catherine (*see* SINAI). One of its 7th-century abbots, St. John Climacus, was

named from his great work, the "Ladder (*klimax*) of Divine Ascent," a classic textbook of the ascetic and spiritual life that every Orthodox monk is supposed to read during Lent.

(D. J. C.)

**Byzantine Empire and Modern Greece.**—Byzantine monasticism found its inspiration in the twofold eremetic and cenobitic tradition of Egypt which in the 4th century spread to Asia Minor, Syria and Palestine, as well as Europe. Though Basil of Caesarea left no rule in the strict sense of the word, his interpretation of the common life as shown in practical tradition and in his writings was widely followed (*see* BASIL, SAINT, the Great). In Asia Minor and the Greek provinces monasticism was as flourishing as that in Palestine and Syria described above. Archaeological surveys in southwest Asia Minor (Lycia) have revealed literally hundreds of monastic sites. Similar development took place in other areas, as Mt. Latmus near Miletus, or Mt. Olympus in Bithynia before the Seljuk invasions of the 11th century, or in south Italy before the loss of the provinces to the Normans. From the 10th century onward Mt. Athos (*q.v.*) developed into a monastic centre whose influence was felt far outside the empire, especially in Slav countries. Athos was also an increasingly potent factor in the Byzantine empire of the later middle ages, particularly in connection with the religious dispute known as hesychasm (*q.v.*). Within the capital city an important centre was the Studite house in the southwest district, whose early-9th-century abbot Theodore Studites both by example and writing greatly influenced the cenobitic tradition.

Conciliar and patriarchal rulings, foundation charters and imperial laws regulated the life of monastic houses, lauras and anchorites, defining their relation to diocesan authority. Foundations were freely made by churchmen and by laity. Normally they were eparchial and under diocesan control, but they might have the privilege of coming under direct patriarchal control; "imperial houses" were subject to the emperor or his representative, and completely independent houses (*autodespotai*) were withdrawn from all control. The regulation of ever increasing monastic temporalities was a perennial problem, and the system of entrusting monastic lands to a "protector" (*charisticarius*), though open to abuse, was much used.

Entry to monastic life was carefully regulated. For instance the position of children, slaves, married or betrothed parties was defined, as well as the problem of *stabilitas loci*; i.e., remaining always in the same monastery. The Council of Constantinople (861) laid down a normal three-year novitiate, but later practice sometimes reduced this to one year, e.g., St. Athanasius' foundation charter for the laura on Mt. Athos in the 10th century. In the liturgical book, the *Euchologion*, the ceremony of frocking a monk or nun is given, with the profession of poverty, obedience and chastity, as well as of *stabilitas loci*.

The head of the cenobitic house was an abbot (often called *hegumenos* or *kathegumenos*) elected in accordance with procedure laid down in the foundation charter; the election was normally confirmed by the diocesan bishop and was usually for life. Within his house the abbot could call upon absolute obedience and was ultimately responsible for its spiritual and temporal well-being. The common life was centred in the liturgical office, consisting of day and night services together with the "divine liturgy" (Eucharist). As in a western Benedictine house, side by side with corporate worship, time was found for instruction and private devotion. Each monk also had to share the daily work of administration and the performance of such other specific duties as might be assigned to the community by the founder, as for instance care of the poor or supervision of medical services (for Byzantine monasticism served the community in many such ways).

Though Byzantine monasticism did not produce "orders" exactly comparable with those of the Latin world, its houses, or groups of hermits, were sometimes federated under a leader (often called a *protos*), and a cenobitic foundation might have its dependencies or groups of individual cells or hermitages. Cenobitic and hermit life were indeed to some extent interdependent, in that a cenobite might become a solitary for a time and perhaps return to his house later on. Something of the significant place of monasticism in the life of Byzantium can be seen from the many extant lives of the saints, and its tradition of spirituality illuminates the writings of such great abbots as St. Simeon (*q.v.*), the New Theologian.

Some medieval foundations, as those of Athos or the houses of the Meteora (*q.v.*) in Thessaly, continue to maintain their unbroken tradition, though with greatly reduced numbers and depleted resources.

(J. M. Hy.)

**Slav Countries.**—Monasticism was brought to the Slav countries together with Christianity itself.

The outstanding representative of the ascetic life in Bulgaria was John Rylski (10th century), who founded the famous monastery of Ryla, the principal centre of spirituality in Bulgaria.

Serbian monasticism developed especially from the 12th to the 14th centuries, when it was under the protection of the kings of the Nemanya dynasty. The most famous monasteries, still decorated with Byzantine frescoes, were those at Studenitca, Zisa, Gracanitsa, Decany and Old Ravanica. After the fall of the Serbian kingdom and during the Turkish occupation, 30,000 Serbians emigrated *c.* 1690 into southern Hungary, where they built 16 monasteries on the Fruska Gora (now in Yugoslavia).

Popular monasticism in Russia is linked with the foundation of the Pecherskaya laura in Kiev by Anthony and Theodosius in the 11th century. The former was an eremitical ascetic, heir to the spirituality of Sinai and of Athos, while his disciple Theodosius gave to the laura the Studite rule and was the first to organize cenobitism in Russia. Thereafter monasticism increased and flourished around Kiev. One of the results of the Tatar invasion in the 13th century was the decay of monasticism in the cities, though the eremitical settlements in the far northern forests continued to flourish. The perfect example of the saintly hermit who became founder of a monastery is St. Sergius (*q.v.*) of Radonezh, who founded the Troitse-Sergiyevo laura at Zagorsk near Moscow in the 14th century. During the 15th and 16th centuries monasticism spread throughout the country, and two conflicting tendencies appeared: that of central Russia, around Moscow, where St. Joseph (*q.v.*) of Volokolamsk, the reorganizer of cenobitism, was the representative of the social and active life (which proved dominant); and that of northern Russia, where the Transvolgians inherited the evangelical spirit of poverty and Hesychastic spirituality. Their chief defender was Nil Sorsky (d. 1508), the great adversary of monastic property and of monks' undertaking social and political activity.

In the reign of Peter I the Great a severe control was kept over monastic property, which was secularized by Catherine II. The number of monasteries and of novices was strictly limited. In the 17th and 18th centuries it was in the monasteries that authentic Orthodox piety took refuge, and a great intellectual and spiritual movement of return to the patristic sources of Orthodox mystical tradition began. The influence of Paissy Velichkovsky, a Hesychast Athonite monk, spread over Russia thanks to his translation of the *Philokalia*, a collection of quotations on mystical theology from the Greek Fathers compiled by Nicodemus the Athonite. In the 19th century pilgrimages were made to the *startsi* of the Optina Pustynye and to St. Seraphim of Sarov, one of the greatest Russian saints.

After the Russian Revolution of 1917 the monks were expelled and the monasteries destroyed if they were not worth preserving as national monuments of art. But after World War II there was some renewal of monastic life. (*See* STARETS.)

**Rumania.**—In Rumania the eremitical form of monasticism predominated until the 14th century, when the Athonite monk Nicodemus began to reorganize cenobitic life in Walachia and Moldavia. The monasteries of Vodita and Tismana were built under his direct supervision, and his disciples helped found the powerful monastic centres of Neamtu and Bistrita. At the end of the 18th century Paissy Velichkovsky was associated with the penetration of Hesychasm into Rumanian spirituality. Rumanian monasticism maintains that tradition today. The laicizing tendencies at the end of the 19th century and the unfavourable political conditions after the Communists came to power in 1945 greatly reduced the outward influence of monastic life in Rumania.

**Nature of Orthodox Monasticism.**—The fact that the Orthodox Church has no variety of religious orders like the west and that its monks are devoted primarily to prayer does not mean that its monasticism is unrelievedly uniform or that it takes no part in active life. On the contrary, the hesychast spirituality, centred on the Jesus prayer, far from isolating a man from his ecclesiastical or monastic community becomes in fact the condition of his spiritual integration with the community. Although for historical reasons the Orthodox Church has usually appointed its bishops solely from hieromonks (monks who are priests), monasticism remains basically a lay institution, distinct from holy orders by its prophetic character and its own vocation to follow faithfully the whole call of the gospel. (B. A. Bo.)

## Western Monasticism

**Early Developments.**—Monasticism was slow in moving westward; its expansion was due at first to the inspiration of the exiled Athanasius and the subsequent diffusion of his *Life of Anthony*, but its beginnings were with individual ascetics or semiprivate groups in such cities as Rome and Trier. On reaching the west, the monastic idea bifurcated. On the one hand it was adopted in a modified form by Augustine at Tagaste and Hippo, by Eusebius at Vercelli, and elsewhere as a way of life for the clerics of the bishop's household or to perform the liturgical services at a city basilica. On the other hand it was followed more austerely by numerous individual ascetics and hermits, especially in Provence and Aquitaine, and in central Gaul it found a focus and leader in St. Martin (*q.v.*), bishop of Tours. From his great monastic complex of Marmoutier, evangelists went out in every direction. In particular, the Gallic monasticism took root in Ireland, where it blossomed into something unique in Christendom: large tribal monasteries controlled districts in which the abbot was in effect bishop while a monk under his obedience in episcopal orders performed the necessary consecrations. This monasticism, which, though physically austere and penitential, developed a high literary culture, swarmed over to the western isles and the Celtic fringe of north and south Britain, while pilgrims made their way farther afield to the continent, carrying fresh practices and learning to central Gaul, to the Jura (Luxeuil) and even to north Italy (Bobbio).

The early forms of monasticism in Italy and Gaul long lacked a comprehensive code of life. The basis of discipline and doctrine was provided by Johannes Cassianus, who was born in what is now Rumania and had become a monk in southern Gaul and subsequently visited the ascetics of the Egyptian and Syrian deserts. He transmitted their wisdom in his *Institutes* and *Collations*, both of which had immediate influence of incalculable force, the latter in particular becoming one of a small group of spiritual classics that have molded the form of Christian life. Neither Cassianus, however, nor his younger contemporaries provided a satisfactory rule. The need was met by Benedict of Nursia, first at Subiaco and then at Monte Cassino. His rule, possibly written for wide application at the command of authority, not only provided the essential legislation for a monastic family but revealed a personality and a master with a unique blend of wise humanity and evangelical strength. Though many of its precepts and phrases are derivative, the rule itself is profoundly original, giving in outline all the directions spiritual, ascetic and economic for the conduct of a self-contained and self-sufficient family, together with ripe and rich advice on both the human and spiritual level. (*See* Benedict, Saint: *Rule of St. Benedict*.)

The rule spread gradually, by virtue of its excellence, often coexisting with, and ultimately supplanting, other directories. The monk in St. Benedict's plan had no work to do for society apart from his duty of Christian charity to his neighbour and to strangers. A contemporary of St. Benedict, Cassiodorus, the former minister of Theodoric, had other views for his monastery of Vivarium in Calabria. There the monks, by copying manuscripts, were to keep alive and to transmit the heritage of literature and knowledge of Rome. Vivarium and its program did not long endure, but the idea remained and in due course was grafted upon the simpler scheme of Benedict. Hitherto, the monastic order had been essentially the search by the individual for integral Christianity in an ailing world. Henceforward for more than six centuries—the "Benedictine centuries," as they have been called—the monasteries were to become an established and influential part of contemporary life.

**The "Benedictine Centuries."**—The prime mover in this period was Pope Gregory the Great. Himself a monk, he encouraged and protected his order in every way. He did more: by using monasteries as bastions against the Arians and by sending a group of monks from his own monastery to preach the faith in England, he made of the monks a papal *corps d'élite* to be used in spreading the gospel among the new peoples of Europe and in binding them directly to Rome. Meanwhile, in the north, Celtic monasticism, after crossing from north Ireland and establishing itself at Iona under St. Columba, moved southward to Melrose and Lindisfarne with Aidan and Cuthbert. The Celtic stream met the Roman at Jarrow and Ripon, and in the end the Roman Benedictine current proved the stronger. From the union of the two sprang the wonderful flower of Northumbrian monasticism which re-created the simple patriarchal life of the Benedictine rule while at the same time producing in Bede and his contemporaries a focus of scholarship and art without rival in western Europe. With Anglo-Saxon England also began the three centuries of monastic evangelization. Willibrord of Ripon and York became the apostle of what are now the Netherlands and Belgium, Wynfrith (Boniface) of Crediton the still greater apostle of Germany. Nearer to home the Northumbrian Alcuin became under Charlemagne the schoolmaster of Europe, while English and Irish monks continued to found and fill abbeys in the area now covered by Germany, France and Switzerland.

By this time a great change had come about in monastic life on the continent. The monasteries found themselves the sole legatees of the learning, literature and education of the past, both sacred and profane; by copying manuscripts of the classics and the Church Fathers and by literary and historical composition they became the reservoirs and fountainheads of civilization to which the modern world owes the preservation of such Latin literature of all kinds as has survived. In this task the principal centres were France, the Rhineland and south Germany, with Tours, St. Gallen and Fulda among the sources of light. During this period the typical small, isolated, self-contained monastic family of St. Benedict's rule was replaced in almost every country by the landed abbey with its vast complex of buildings and services that formed the social and administrative centre of a great feudal estate. Within it some were occupied in administration, while others were engaged in teaching and studying, and the intellectual character of much of their work gradually converted the predominantly lay population of the monastery into one of priests and clerics, whose chief task was to perform lengthy liturgical services. The monks had become an essential part of Christian society, the class that praised God and made intercession on behalf of the rest.

With the lapse of centuries the need for external organization and disciplinary union between monasteries became more and more evident. Many abbeys in France and elsewhere were engrossed by magnates or bishops and thus lost their abbot in all but name; others became lax and decadent. The first serious attempt at widespread reform was made under Charlemagne, who decided to enforce unity of observance throughout his empire with the rule of St. Benedict as the governing code. Under his son Louis I the Pious, in 817, at an assembly of monks at Aachen, a detailed code and directory were promulgated that should be binding on all. The central authority and the statutes soon ceased to function, but the legislation was there to serve as a norm and model for future reforms, and for the first time monks of the empire had become conscious of their unity as a tribe under one patriarch, the *familia S. Benedicti*.

The 9th century was one of the darkest in monastic history, but the 10th saw the foundation (910) of Cluny in Burgundy. Cluny was blessed by a succession of able, saintly and long-lived abbots, who successfully maintained their independence of every authority, whether lay or ecclesiastical, save the papacy, and gradually acquired dependencies which the third of the great abbots, Odilo

(ruled 994–1049), began to form into a family. A common observance was imposed, and the dependencies were bound strictly to the abbot and chapter of Cluny. Cluniac houses gradually increased to well over a thousand scattered over the whole of western Europe save for the British Isles and portions of southern Germany. The share of Cluny and other monasteries in the church reform of the 11th century has often been exaggerated, but the great body of monks, from whose rank many of the principal reformers had issued, undoubtedly played a great part in giving that reform its strongly monastic character. (*See* also BENEDICTINES.)

Meanwhile an entirely new movement of monastic renovation appeared in north Italy in the shape of two new orders which combined in different measure the eremitical and cenobitic ideals. The family of Camaldoli (*c.* 1012) was composed of groups of hermits living within a single enclosed area; the order of Vallombrosa (*c.* 1030) added to a strict interpretation of the rule of St. Benedict a remote and solitary site. At both there was a further innovation: illiterate brothers performed the domestic and many of the administrative services. (*See* CAMALDOLESE; VALLOMBROSIANS.)

The conception of a reform in the direction of austerity and solitude soon crossed the Alps; at La Grande Chartreuse and Grandmont the eremitical element was foremost, while the monks of Tiron and Savigny adopted an austere form of the normal Black Monk life. All these new ventures, however, were soon overshadowed by the monks of Citeaux (*q.v.*). This house in Burgundy, founded in 1098, began as a small and remote abbey, but the presence of men of holiness and ability, such as the Englishman Stephen Harding, and the arrival in 1112 of the young St. Bernard (*q.v.*) with numerous relatives and friends, stimulated recruitment, and the stream soon assumed vast dimensions. The first fathers of the "White Monks" had stressed the literal observance of the rule, avoidance of all economic and social entanglement with "the world," and a timetable far simpler than that of Cluny, with set periods reserved for manual and field labour of every kind. When foundations were made, a short document, called the *Carta caritatis* ("Charter of Charity"), established a system of visitation and annual general chapters to preserve discipline, unity and absolute uniformity. In addition, the lay brothers or *conversi* were made an integral part of the monastic family and used to build and staff the monastery and to act as labourers and herdsmen on the land. In consequence, the Cistercians emerged as a closely knit federation of autonomous abbeys, a real religious order, forming with their economy, which was at once dispersed in granges and centralized in the abbey, and with their hosts of lay brothers, a vast, well-ordered family. Their success was spectacular. At the death of St. Bernard (1153) they had houses all over western Europe. They inspired other bodies, such as the Premonstratensians and military orders, to imitation, and their characteristic institutions of frequent visitation and annual general chapter were adopted by all subsequent religious bodies. (*See* also CISTERCIANS.)

With the death of St. Bernard, the "monastic centuries" entered their phase of decline. For another hundred years the monks continued to be a spiritual and a cultural force, though the friars (*see* MENDICANT) in one field and the universities in another were taking the place that had been theirs; and for yet two centuries more the greater abbeys filled an important place in society. There were, moreover, several new movements of reform in Italy which gave birth to new congregations destined to a long life, such as the Sylvestrines (1247), the Celestines (1264) and the Olivetans (1344). On the whole, however, it was as landed capitalists, as feudal magnates and as wealthy corporations that the influence of the monks was now felt. The wars and pestilences of the mid-14th century had their share in thinning the ranks and shaking the economy of the monks, but the real cause of their subsequent decline lay deeper.

**The Later Middle Ages.**—Meanwhile, the centralizing and formalizing tendencies of the age had their influence on the monks. At the fourth Lateran council (1215) Innocent III had united the Black Monks in provincial chapters for the purpose of legislation and visitation. In the following century Benedict XII imposed on both Black and White Monks a series of reforming decrees which, while aiming at uniformity and exactness of observance, and regulating the movement of monks to the universities, countenanced some of the changes and relaxations that had come in with the changing times. Thenceforward for more than a century the monastic order declined in regularity, stricken in most continental countries by the plagues of commendatory abbots (*see* COMMENDATION) and spiritually unfit recruits, and everywhere by gradual relaxation.

Nevertheless, the end of the middle ages saw two notable reforms. One was the congregation of Sta. Giustina of Padua, founded by Ludovico Barbo, a Venetian, in 1424, later known as the Cassinese congregation. To eliminate the evils of *in commendam* and of powerful, irresponsible superiors, the monks of the congregation were to form a single family. Local superiors were changed annually, and the supreme authority was vested not in an abbot or group of abbots but in the annual general chapter and its committees. This organization was widely copied by reformers after the Council of Trent, as was also its encouragement of learning and study. Equally significant for the future was the Spanish congregation of Valladolid, which originated in a reform of great austerity with perpetual enclosure (1390); in the 16th century it adopted the main lines of the constitution of Sta. Giustina, while preserving the individuality of each house.

**Reformation and Counter-Reformation.**—Meanwhile the monastic life was being radically challenged by powerful enemies. John Wycliffe had attacked the monastic institute as a depravation of the gospel teaching and had urged total secularization. Early in the 16th century Erasmus, using every weapon of irony, wit and learning, represented the monastic life as a mechanized, mercenary and hypocritical form of superstition, while a little later Martin Luther attacked the vows and spirit of monasticism as an anti-Christian and impracticable form of life. This was followed by a wave of suppression and secularization, and by the middle of the 16th century organized monastic life had disappeared from northern Europe, Switzerland and the British Isles, and was soon reduced to ruin in France by the wars of religion.

The Council of Trent and the new spirit of the Counter-Reformation brought about a gradual revival of monasticism, and a number of regional congregations came into being in the Habsburg empire. More significant than these were the two celebrated congregations of St. Vanne (1600) in Lorraine, and its daughter St. Maur (1618) in France. For these two the Cassinese congregation provided the pattern. The congregation, not the abbey, was the unit, and the authority was the annual or triennial general chapter and the superior general; the houses were priories, and the monks could be transferred from house to house. In both the observance was severe and strict, but the lessons of the Reformation had been taken to heart, and the monks devoted themselves to apostolic and theological work, to education and above all to study and learning. The Maurists (*q.v.*), in particular, with their élite of scholars housed at St. Germain-des-Prés (Paris) earned for their whole order the epithet of "learned." At the same time the Cistercians, who had revived after the Reformation, especially in Germany and France, were divided in the latter country by a bitter feud between the parties of moderate and strict reform. Among the latter a still stricter centre, with practices and a spirit all its own, appeared at La Trappe under Armand de Rancé; this community by an accident of survival at the Revolution became the nucleus of an influential congregation in the 19th century.

This period was for monks an untraditional and in some ways an uneasy one. The *ancien régime* and Gallicanism, with its commendatory abbots, royal control and traditions of wealth and birth, existed alongside the new and intense spirituality and new intellectual life, while after less than a century of existence the new institutes were in the grip of Jansenism and *philosophisme* and were avoiding suppression by secularization. Even the spectacular austerity of La Trappe had in it something of the rigidity and coldness of the epoch.

**After the French Revolution.**—During the French Revolution and the ascendancy of Napoleon I, almost all the monasteries of Europe disappeared in one way or another, and only about 30

battered survivors lived on into the new age after Waterloo, among them the three English houses founded in exile two centuries earlier (St. Gregory's, Douai, now at Downside, Somerset; St. Lawrence's, Dieulouard, Lorraine, now at Ampleforth, Yorkshire; St. Edmond's, Paris, now at Woolhampton, Berkshire). The revival, however, was quick in coming, marked among the Benedictines by the rise of the congregations in France at Solesmes under Prosper Guéranger (1837), of Beuron in Germany (1868) and of the Subiaco (later Cassinese) congregation of Primitive Observance in Italy (1872). All these in their final form were a conscious return to the original Benedictine scheme of autonomous houses; and they all became, by accident or design, supranational.

Meanwhile monasticism began to emigrate from Europe. Among the first were the two congregations of American Cassinese (1855) and Swiss-American (1870), engaged in teaching, missionary and parish work in the United States and Canada. Later monks and monasteries scattered all over the world, to South America, central and southern Africa, Australia, China and Japan. Thus the 19th century saw monasticism reviving its influence and appeal in two directions corresponding roughly to its diverse origin in Latin countries and the German and Anglo-Saxon lands—in the former toward a liturgical, claustral life, in the latter toward an expansive activity of teaching and missionary preaching.

Both continue to develop in the 20th century, and despite (perhaps even because of) the disasters and uncertainties of the period the losses and casualties of two world wars were more than made good. Alike in the number of houses and of their inmates, the monastic body has vastly increased since 1900. Since 1945, indeed, a new tendency has been visible; the expansion has been most notable in congregations or groups distinguished by the severity and "contemplative" character of their observance, such as the Carthusians, the Reformed Cistercians and the austere Benedictine congregation of Pierre-qui-Vire in France. It would seem that the primitive appeal of monasticism, the departure from the world to a simpler more austere life of solitude and penance, is more effective than any other, even in the countries of the new world.

In the course of 17 centuries Catholic monasticism has thus assumed many different outward forms and functions in society. Originally an individual retreat from the world for personal self-discipline and sanctification, it gradually became, and remained for a millennium, an important institution and component of medieval society, first as an agency of evangelization and civilization, then as the very heart of learning and reform, and finally as a great economic and social force. During this long period the monks left a permanent mark upon theology, upon literature, upon liturgy and upon the chant; for a century or more, indeed, they permeated the whole Western Church with their interpretation of the evangelical life, and in this their heyday they divided themselves vertically into three classes, monks, lay brothers and oblates or tertiaries, and horizontally into bodies comparable to the colours of the spectrum, ranging from the austere, eremitical Camaldolese and Carthusians, through Grandmont, Cîteaux and the great company of Black Monks, to the monachized regular canons and the later friars. This period ended in northern Europe with the Reformation, but in France, the Latin lands and the Austrian empire it lasted in diminished form till the French Revolution. Meanwhile, from the early 16th century onward, monasticism gradually became once more a vocation, a way of sanctification for the earnest seeker after God. This it remains in the present age. (M. D. K.)

**Anglican Monasticism.**—Although the Church of England in general during the 17th and 18th centuries shared the ordinary Protestant suspicion of monastic communities, there were some theologians and spiritual writers, notably Herbert Thorndike and William Law, who took a more positive attitude toward the monastic life. The example of Nicholas Ferrar and his family community at Little Gidding (*c.* 1630), Huntingdonshire, though not strictly monastic, also pointed the same way. However it was not until the time of the Oxford movement that any of these Anglican aspirations toward monasticism came to function.

The first Anglican communities of women were established in the years after 1845 and at once adopted rules and customs based on those of continental Roman Catholic communities (*see* Women's Religious Orders). They very quickly developed in numbers and undertook a great variety of active works. After J. H. Newman's "monastery" at Littlemore, Oxford, came to an end in 1845, with his reception into the Roman Catholic Church, no serious attempt was made to establish a men's community until 1866, when R. M. Benson founded the Society of St. John the Evangelist (*see* Cowley Fathers) at Oxford. Since then numerous other communities or brotherhoods have been founded in England, of which about eight have established themselves firmly. The largest men's communities are the Community of the Resurrection, Mirfield, Yorkshire (founded by Charles Gore in 1892; *see* Mirfield Fathers), Society of the Sacred Mission, Kelham, Nottinghamshire (founded by H. H. Kelly in 1894; *see* Kelham Fathers); and the Society of St. Francis, Cerne Abbas, Dorset (1921). In 1863 J. L. Lyne ("Father Ignatius of Llanthony") established a Benedictine brotherhood, finally disbanded after his death in 1908. Another attempt to revive the Benedictine life in communion with Canterbury was made by Aelred Carlyle in 1896, but he and 22 of the community on Caldey Island, South Wales, were received into the Roman Catholic Church in 1913. The following year a Benedictine community was reestablished at Pershore, and moved to Nashdom abbey, Burnham, Buckinghamshire, in 1926. It has a branch house in the United States at Three Rivers, Mich. The only indigenous men's community of any size in the Protestant Episcopal Church is the Community of the Holy Cross, West Park, N.Y. (1881). Several English communities of men and women have branch houses overseas. Some have established independent congregations.

The Church of England has never made provision for religious communities by way of canonical legislation, and their relations with the ecclesiastical authorities were at first vague and undefined. Since 1935 it has been possible for those in England to obtain formal recognition from the advisory council on religious communities established for the provinces of Canterbury and York. Anglican communities of men work in the British Isles, United States, Canada, Australia, Japan, India, South Africa and the West Indies. No up-to-date statistics are published, but in general these communities are not large. (P. F. A.)

**Protestant Monasticism.**—Protestants have been traditionally suspicious of monasticism, and particularly of any suggestion that it represents a higher form of life than can be lived within Christian marriage and engagement in the world. Nevertheless, insofar as the cloister offers a "parable" of Christian renunciation, Protestantism could not avoid reproducing some of its more positive features. It was the evangelical concern of Pietism which first produced a reexamination of the vocation to celibacy, community and obedience and which led in the 19th century to the foundation of the European deaconess orders, whose way of life approximates in certain respects the life of active orders of women in the Roman Catholic Church (*see* Deaconess).

During the 20th century the liturgical revival centring in the sacraments has led to the foundation of a number of societies of clergy and laymen, whose members continue to live in the world but are bound by a common rule, such as the Societas Sanctae Brigittae (1920) in Sweden and the St. Michael's brotherhood in Germany (1931).

Since World War II this movement has taken a further step among both Reformed and Evangelical Christians in Europe. Several communities for women have been established in Germany and Switzerland, while in France the Taizé community for men has developed in the village of Taizé near Cluny (*see* Grandchamp and Taizé Communities). The brothers accept life engagements to celibacy, poverty and obedience, and their life resembles in almost every way that of similar Roman Catholic communities. In all these communities the ecumenical element has been strong, and they have consciously sought to learn from all periods of the church's history.

These modest experiments did not come into being primarily as monastic ventures but should rather be seen as part of a greater movement for the renewal of the church's life and witness, which for any adequate treatment should include the Evangelical acade-

mies and lay centres in Germany, the Iona community in the Church of Scotland, Agape in the Waldensian church in Italy and the Christian *ashrams* in India. (R. S. P.)

**Conclusion.**—In all these centuries the basic ideal of monasticism has been the same: the conquest of spiritual evil by means of the renunciations expressed in vows of poverty, chastity and obedience, thus freeing the soul for the perfect love and service of God. But monasticism in the west has acquired certain additional notes in the course of the ages. Since the early middle ages it has devoted itself particularly to liturgical worship and intercessory prayer and to some forms of literary learning, and concurrently it has in varying extent undertaken works, and even external works, such as apostolic, pastoral and educational service. These latter, while fully consistent with a life of holiness and Christian perfection, can scarcely be contained within any definition of monasticism that is to be significant. This must always imply a large measure of retreat from secular activity and of personal solitude. The principal foes of the monk, human frailty apart, have always been wealth and entanglement with things of the world.

While monasticism will not, in any foreseeable future, regain its former social and economic importance, the ideal is as precious and powerful as ever in the spiritual life of the church, though it is in danger of being submerged in the waters of external activity. (M. D. K.)

## MONASTICISM IN OTHER RELIGIONS

Ethnic religion, whether primitive or developed, is generally world affirming and does not encourage withdrawal. Hence Shintō in Japan has no monasteries. Among more developed religions with a prophetic basis, Zoroastrianism, like Orthodox Judaism, is also nonascetic and world affirming.

**Beginnings.**—The earliest type of monk was probably the solitary or hermit; *shramanas* (Sanskrit "recluse") may already have existed in some of the earliest proto-Dravidian or pre-Aryan settlements in India (*i.e.*, before *c.* 1500 B.C.). In early Hindu times (*c.* 600–*c.* 200 B.C.) there were hermits who lived in groups (*ashramas*) although they did not lead a strictly organized communal life. Literary references indicate that such practices were probably widespread, and this readiness to abandon everyday life may be explained partly by the pressures of climate, famine, plague, overcrowding or poverty, and partly by the desire, clearly typical of the Upanishadic literature of the period, to achieve permanent communion with deity.

**Jainism.**—Organized monasticism seems to have evolved from the communities of *ashramas*. Perhaps the first religion that can properly be said to have had an organized monastic life was Jainism (*q.v.*), whose reputed founder, Mahavira, organized his followers into groups of monks and nuns, who were fully professed, and laity, who ministered to their needs and kept a less rigorous rule. Later the Jains split into two sects, and one of these, the Digambaras, disallowed nuns. In Jainism self-denial and mortification assumed an extreme form. Its monks eschew the destruction of any animal life; some reject clothing altogether, and many fast to death. The strictness of their rule remains unmodified in the 20th century.

**Buddhism.**—Buddhism, a preeminently monastic religion, led to a great increase in the number of large organized monastic communities, known in totality as the organization of the Sangha. At first the monks led the wandering life of beggars, gathering informally in huts for the rainy season; later permanent monasteries were built, and the system became more stereotyped. The Buddhists, like the Benedictines of Christianity, observed a moderate rule, avoiding extremes of self-indulgence and self-immolation; according to tradition, Gautama Buddha had practised and rejected extreme ascetic exercises, the austerity of which suggest that he was at one time a member of a Jain community. Like the Jains, the Buddhists ignored caste distinctions. Originally monks and laity were closely associated, a tradition which has continued in the Theravada countries, and in general the Sangha has adapted itself to the needs of the people; for example, it has admitted a great many young men as temporary novices who for a few months lead the life of a *bhikkhu* (Pali "monk") and receive education and religious instruction. This practice is still customary in Burma, Thailand and Cambodia.

The number of Buddhist nuns has never been large; indeed the Buddha is said to have been very reluctant to allow women to form communities. They lived apart from the monks and were always considered inferior to them. There are still a few communities to be found in Buddhist countries.

The Zen movement, which began in China in the early 5th century A.D., attempted a return to the early principles of Gautama and had a marked effect upon the monastic communities adopting it. It stressed frugality of diet, simplicity of dress and the duty of monks to work as well as to meditate. In these respects it was not unlike some reformed Benedictine communities among Christians. The monastery buildings are of severe pattern and austere furnishing, and Zen art, although it is extremely beautiful, is not ostentatiously displayed. There are three meals a day, the only one after noon being the remains of what is left over from the other two. The exacting meditation periods alternate with walking exercise round the central hall. Zen monks exhibit a Franciscan gaiety and cheerfulness during their daily occupations. *Koans*, or paradoxical aphorisms, are prescribed as subjects for meditation, and twice a week the head of the community interviews each member to see what progress he has made.

(*See* BUDDHISM: *Early Order of Monks* and *Modern Buddhist Practice*, which discusses the differences in the monasticism of the two great schools of Buddhism, Theravada and Mahayana; *see* also TIBETAN BUDDHISM.)

**Taoism.**—This movement in China, being essentially quietist, has developed a few monastic communities in which meditation can be practised and which are somewhat akin to those of the Buddhists. (*See* TAOISM.)

**Hinduism.**—In the 9th century A.D., possibly as a result of Buddhist influence, the Hindu philosopher and theologian Shankara founded four monastic communities (*maths*)—at Badrinath in the Himalayas, Dwarka in the west, Puri in the east and Mysore in the south—which are still active.

According to the rule Shankara laid down, there was no central head of the order, and each abbot nominated his successor. He was enjoined to travel through his own province, preaching *dharma*; *i.e.*, one's station and its duties according to the Hindu scriptures. In the 12th century another famous theologian, Ramanuja, founded several religious orders and is thought to have left behind him as many as 700 monastic communities; but these have not endured. It is said that he allowed members of his order to marry and that many of the institutions came to have hereditary abbots. Like the Buddhist and Jain monasteries before them, and their Christian counterparts in the near east and western Europe, Hindu monastic communities became centres of learning. (*See* also HINDUISM: *Asceticism*.)

**Islam.**—Muslim communities are discussed in the articles SUFIISM; DERVISH.

**Modern Developments.**—The decline of asceticism in India is marked, and with it there has been a decline in the number of monastic communities. The Indian Buddhist monasteries had disappeared by about the 13th century, partly as the result of the Muslim invasions, and they are now only deserted ruins. The aggregations of ascetics and hermits at Varanasi (Benares) have diminished considerably. India is, in fact, so busy transforming itself that it has less and less time for world renunciation. In China, Buddhism and Taoism are being superseded by Marxism.

**MONAZITE,** a mineral consisting of the phosphate of the cerium and lanthanum group of rare-earth elements including neodymium. Small and variable amounts of thorium, 2%–12%, and of yttrium are usually also present. The world's supply of thorium (*q.v.*) was very largely obtained from monazite. Thorium is converted by neutron bombardment into a fissionable isotope of uranium and can be employed in atomic power reactors; the oxide thoria formerly was used on a large scale for the manufacture of mantles for incandescent gas lighting. The cerium (*q.v.*) is used for chemical and ceramic applications, and alloyed with iron it forms the sparking flints of automatic lighters.

Monazite is of wide distribution as minute crystals in granites and gneisses, being present in very small quantity as an accessory constituent of these rocks. By powdering the rock and washing away the lighter minerals in a stream of water, the heavy minerals (zircon, rutile, magnetite, garnet, monazite, ilmenite, etc.) may be collected. This separation has been effected naturally by the weathering and disintegration of the rocks and the accumulation of the heavier minerals in the beds of streams. Under these conditions monazite has been found as rounded grains in alluvial gold washings and as a constituent of the black-sand fraction of beach and river sands. It also occurs in geologically old placer deposits (cemented conglomerates), as in the Witwatersrand in South Africa and the Black hills of South Dakota. Large masses of monazite are found in pegmatite veins, as in Madagascar, Quebec and North Carolina (where a crystal weighing 59 lb. was found). Vein deposits of massive granular monazite are known in San Bernardino county, Calif., and the van Rhynsdorp district, Cape of Good Hope, S.Af.

Important commercial deposits of monazite are found in the beach sands of Travancore in southwestern India, in the states of Espirito Santo and Bahia, Braz., in New South Wales and Queensland and in Ceylon. In the United States, monazite deposits are found in Florida, the Appalachian region, Idaho and Montana. The crude sands, known as monazite sands, usually are first concentrated by washing, and the monazite and other minerals are then separated magnetically.

The composition of monazite is represented by the formula $(Ce,La,Nd)PO_4$; thorium is present as thoria ($ThO_2$). Crystals of monazite belong in the monoclinic system, and are usually flattened parallel to the orthopinacoid. The large crystals from pegmatites usually are reddish brown, dull and opaque and simple in form, while the small translucent honey-yellow crystals from the Alps are bounded by numerous bright faces. The hardness is 5.5 and the specific gravity 5.1–5.2. *See also* Rare Earths. (L. F.)

**MONBODDO, JAMES BURNETT,** Lord (1714–1799), Scottish jurist, nonconformist and imaginative writer on natural history and the origins of society, was born at Monboddo, Kincardineshire. A classical scholar, he studied at Aberdeen and Edinburgh. He was made a lord of session in 1767 with the title of Lord Monboddo.

In his *Antient Metaphysics* (1779–99) Monboddo conceived man as gradually elevating himself from an animal condition to a state in which mind acts independently of body. In *The Origin and Progress of Language* (1773–92), he related man to the orangutan. His speculations were an odd jumble of insight and fancy with some curious points of contact with Darwinism. He died on May 26, 1799.

Boswell's *Life of Johnson* gives an account of Johnson's visit to Burnett at Monboddo, and is full of references to the popular notion of an eccentric man who thought that the human species could be related to apes.

Bibliography.—W. Knight, *Lord Monboddo and Some of His Contemporaries* (1900); A. O. Lovejoy, *Essays in the History of Ideas* (1948); W. F. Gray, "Lord Monboddo and Lord Braxfield," in W. H. Davenport (ed.), *Voices in Court* (1958).

**MONCEY, BON ADRIEN JEANNOT DE,** Duc de Conegliano (1754–1842), French marshal remembered for his successes in Spain during the French Revolutionary and Napoleonic Wars, was born in Besançon on July 31, 1754, the son of a lawyer. The light infantry regiment in which he was an officer was stationed in the western Pyrenees from 1788 and was one of the few regular units there when Spain declared war on Revolutionary France in 1793. After the repulse of the Spanish attack on the Bidassoa river (Feb. 1794) he was promoted to the rank of general. He then led a division in a long march that outflanked the Spaniards; the frontier was cleared and the French took San Sebastian. The Jacobin *représentants en mission* gave all the credit for this to Moncey, and in Aug. 1794 he was given the command of 50,000 men. With these he executed wide encircling movements, from which the Spanish forces usually escaped with the loss of their materiel. Moncey took care not to antagonize the Spanish people by acts of terrorism. He had taken Bilbao and reached the Ebro and was preparing to besiege Pamplona when the Franco-Spanish peace of Basel (June 1795) brought the war to an end.

Moncey, after holding corps commands in Italy, was in Dec. 1801 appointed inspector general of the gendarmerie. He thus uneasily shared the police control of Napoleonic France with Fouché and Savary. He was made a marshal in 1804 and duc de Conegliano in 1808. He served in Spain again in 1808 and, after the Bourbon Restoration, in 1823. Governor of the Invalides from Dec. 1833, he died in Paris on April 20, 1842. (I. D. E.)

**MÖNCHENGLADBACH,** a town of Germany in the *Land* (state) of North Rhine-Westphalia which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 152,185. It is situated between the left Lower Rhine and the Meuse, 16 mi. W. of Düsseldorf, and is an important centre for main roads and railways. It also has a civil airport. Mönchengladbach is a noted textile centre, producing cloth (particularly worsted). It also has metallurgical and machine industries (especially textile machinery), iron foundries and assembly plants for aerotechnical equipment. Other factories produce paper, chemicals, leather, foodstuffs and petroleum.

The town developed around a Benedictine monastery (founded in 792 and suppressed in 1802, whence *Mönchengladbach* ("monks Gladbach"), and was chartered in 1316. Historic buildings in-

clude: the 11th-century Romanesque minster with an Early Gothic choir (attributed to Gerhard von Riehl of Cologne), an early 13th-century nave and an 8th-century crypt; a baroque town hall, formerly a Benedictine abbey; the Late Gothic church of St. Mary's Ascension; and a 12th-century convent in the Neuwerk quarter. The town is well endowed with parks and has a botanical garden (Bunter Garten) and several sports arenas (including bicycle and roller-skating stadiums, a race course and, on the outskirts, a motorcycle and racing-car circuit called the Grenzlandring). Institutes of higher learning include the Franciscan John Duns Scotus academy (philosophy and theology), colleges of textile engineering and agriculture and a higher school of economics. The municipal museum houses a notable collection of Coptic textiles. The town is renowned for its choral societies and has a municipal theatre. It is the headquarters of the North Atlantic Treaty organization forces in north-central Europe.

**MONCK** (MONK), **GEORGE,** 1st DUKE OF ALBEMARLE (1608–1670), English parliamentarian general and architect of the Restoration, was born at Potheridge in Devon on Dec. 6, 1608. He was the second son of Sir Thomas Monck, who belonged to a well-established family in the west of England. Little is known about his education, but at the age of 16 he volunteered to fight under a kinsman, Sir Richard Grenville, in the duke of Buckingham's military operation against Cadiz and later went on the expeditions to the Ile de Rhé and La Rochelle, all of which were failures. Later he served under Lord Vere in the Netherlands, fighting for the Dutch against the Spaniards and distinguishing himself at the siege of Breda in 1637. Through the influence of the earl of Leicester, he was appointed lieutenant colonel of a regiment of foot which took part in the two Bishops' Wars against the Scots. In 1642, again with Leicester's help, he was given acting command of a foot regiment in Ireland which was used against the rebels.

The following year he joined a force sent from Ireland to England to help Charles I against the parliamentarians in the Civil War, but was captured at Nantwich, in Cheshire, in Jan. 1644. He spent the next two years as a prisoner in the Tower of London where he wrote a book, *Observations Upon Military and Political Affairs*, published posthumously in 1671, which reveals him as a deep-thinking professional soldier. He had evidently made a reputation in his profession, for when the Civil War was over the parliamentarians sent him back to Ireland where he served them as major general in Ulster. After the execution of Charles I an alliance concluded between the English royalists, Irish nationalists and Ulster Scots compelled Monck to agree to an armistice. He was afterward censured for this action by parliament on political grounds but excused because of military necessity. Nevertheless he was deprived of his regiment and retired to Devon.

Oliver Cromwell, who respected Monck's military ability, took him to Scotland in 1650 and formed a foot regiment for him which later became the Coldstream guards. Monck played an important part in the battle of Dunbar on Sept. 3, 1650, and when Cromwell returned to England in 1651 he left Monck behind as commander in chief with an army of 5,000 men. Monck completed the subjugation of Scotland. By some he was blamed for his severity at the storming of Dundee on Sept. 1, 1651, but on the whole his discipline was complete and effective. Later that year he was taken ill and retired to Bath for treatment, though he remained a parliamentary commissioner for Scotland. In the autumn of 1652 a new phase in Monck's career opened when he was appointed one of the three generals-at-sea at the outbreak of the first Dutch War (1652–54). Possibly his experience in handling artillery explains his appointment. He took part in the principal sea battles and appears to have influenced the development of naval tactics. According to the naval historian C. T. Atkinson, Monck can stand comparison with the famous Dutch admiral M. H. Tromp (*see* TROMP) as a strategist and tactician, if not as a seaman.

While the Dutch war was in progress a rising had begun in the Scottish Highlands and at the end of 1653 Monck was ordered to return there as commander in chief. After he had collected the necessary funds and forces and received the support of Cromwell, who was then lord protector, he carried out a brilliant campaign in the Highlands and afterward organized their security with so much success that he was able to reduce the size of the English garrison in Scotland. His loyalty to the Cromwellian protectorate was complete.

When Cromwell died Monck advised Oliver's son, Richard, who was no soldier, to rely on the "new courtiers," who had served his father well, rather than upon the intriguing generals, and to amalgamate some of the regiments so as to rid himself of disloyal officers. But the new protector did not follow this advice. "Richard Cromwell forsook himself," Monck is said to have remarked later, "else I had never failed my promise to his father or my regard for his memory." Monck acquiesced in the overthrow of the protectorate and the recall of the Rump parliament, the remnants of the original Long parliament of 1640. But when in Oct. 1659 Maj. Gen. John Lambert (*q.v.*) dissolved the Rump by force, Monck refused to recognize the new rulers and informed the speaker of the house of commons that he would free his country from "the intolerable slavery of a sword government." He then began to purge his own army in Scotland and although, to gain time, he entered into negotiations with Lambert he insisted finally that he must restore parliament. Monck set up his headquarters at the village of Coldstream on the Scottish border on Dec. 8 and on New Year's day, 1660, led an army of six infantry and four cavalry regiments into northern England. He entered York on Jan. 11. Lambert's army, which was to oppose Monck, melted away, and Monck reached London on Feb. 3 to receive the thanks of the Rump parliament, which had reassembled the previous Christmas.

Although royalist agents had approached him in the preceding autumn there is no reason to suppose that when Monck marched on London he had any intention other than to obey parliament. However, during his march petitions had reached him asking for the summoning of a "free parliament" and he told the Rump that it should fill up its vacancies and then dissolve. The council of state ordered Monck to impose discipline on the City of London which refused to pay its taxes until the house of commons filled up its vacancies; Monck at first obeyed, but then himself insisted that the commons should fill up their vacancies and afterward give way to a "free" parliament. It was not until parliament was dissolved in March that he entered into direct communication with Charles II. The new Convention parliament, as it was called, invited Charles II back to England; on May 25 Monck welcomed the king when he landed at Dover. For his services in contributing to a peaceful restoration of the Stuart monarchy Monck was made duke of Albemarle, created a knight of the Garter and awarded an annual pension of £7,000. He was also made master of the horse, lord lieutenant of Ireland and captain-general. But, apart from the Coldstream guards, the splendid army he had fashioned was disbanded. When the plague broke out in 1665 Albemarle stayed at Whitehall to assuage the panic in the capital. In the second Dutch War he returned to active service and defeated the Dutch at St. James's Fight on July 25, 1666. When the Dutch appeared in the river Thames the following year, and also attacked Chatham, he helped to save the English navy from extinction. Nevertheless it is doubtful whether he recovered from this disgrace. Monck died at Whitehall on Jan. 3, 1670.

Monck was above all a fine professional soldier who believed in the virtues of obedience and deference to the civil authority. Only in 1660 was he reluctantly driven to intervene in politics. He had a reputation for being fond of money and close with it. He married Ann Ratsford Jan. 23, 1653. The widow of a farrier, she had been his laundress when he was in the Tower, and his mistress. She bore him several children, only one of whom, Christopher, survived. He became governor of Jamaica and second duke of Albemarle. At his death in 1688 the title became extinct.

*See* also references under "Monck, George" in the Index.

Lives of Monck were written by his chaplain, T. Gumble (1671), and his physician, T. Skinner (1723). Good later biographies are by Julian Corbett (1889) and Oliver Warner (1936). For Monck and the Restoration *see* Godfrey Davies, *The Restoration of Charles II* (1955); and David Ogg, *England in the Reign of Charles II*, 2 vol., 2nd ed. (1955). (M. P. A.)

**MONCTON,** a city and port in Westmorland county, New Brunswick, Can., 25 mi. from the mouth of the Petitcodiac river, a navigable stream at high tide, and 89 mi. N.E. of Saint John by rail. Pop. (1961) 43,840. It is the Atlantic regional headquarters of the Canadian National railways and an air and highway transport centre serving the maritime provinces. Originally settled by French Acadians, it was resettled by Germans from Pennsylvania in 1763. It was named after Robert Monckton (1726–82), lieutenant governor of Nova Scotia from 1756 to 1761. A notable tourist attraction is the tidal bore, a flood of water that advances up the river every 12½ hours at an average height of 3½ ft. (C. W. Rd.)

**MOND, LUDWIG** (1839–1909), British chemist and industrialist who perfected the Solvay ammonia-soda process of making alkali and devised a process for the extraction of nickel, was born at Kassel, Ger., March 7, 1839. After studying at Marburg under H. Kolbe and at Heidelberg under R. Bunsen, and holding several industrial positions in Germany, he went to England in 1862 and became associated with a well-known alkali manufacturer at Widnes, where he elaborated the practical application of a method he had patented for recovering the sulfur lost as calcium sulfide in the black ash waste of the Leblanc alkali process, which he introduced into some 30 works in England and France. He became a naturalized British subject in 1880. In 1873 he entered into partnership with Sir John Tomlinson Brunner (1842–1919), and thus founded the great chemical manufacturing firm of Brunner, Mond and Co. They began to make alkali by the Solvay ammonia-soda process, which process was significantly improved by Mond. About 1879 Mond began experiments in the economical utilization of fuel and his efforts led him to the system (patented 1883) of making the producer gas known by his name, "Mond gas." Further, he worked out a gas battery.

His discovery of nickel carbonyl made possible a successful process for the extraction of nickel from its ores, which involved the finding, acquisition and development of mines in Canada, the elaboration of new and suitable smelting operations there and the invention of highly specialized apparatus for the refining works in Wales.

Mond was elected a fellow of the Royal society in 1891. A liberal contributor to the purposes of research, he founded in 1896 the Davy-Faraday Research laboratory in connection with the Royal institution. He was a notable art collector, most of his paintings being bequeathed to the National gallery. He died in London on Dec. 11, 1909.

*See* Carl Langer in *Berichte der deutschen chem. Gesellschaft*, p. 3665 (1911), which contains a list of his papers; J. P. Richter, *The Mond Collection*, 2 vol. (1910), describes his art collection.

**MONDEGO,** the largest of the exclusively Portuguese rivers, rises at 5,250 ft. on the northern slopes of Serra da Estrêla and its drainage basin covers 2,615 sq.mi. The chief tributaries are the Dão, Alva and Ceira. The Mondego generally follows an antecedent course southwest to the Atlantic for 136 mi. in a broad basin, partly tectonic, with incised meanders in its lower valley. Coimbra stands where it leaves the Beira plateaus for a broad flood plain. A sandbar prohibits navigation above Figueira da Foz, though small craft can sail 53 mi. upstream to Fozdão, the river is tidal to Montemór o Velha (12 mi.). The Mondego and Alva have several hydroelectric stations completed or under construction. Cabo Mondego, a promontory north of the river, rises steeply to 750 ft. above the coast. (J. M. Ho.)

**MONDINO DE' LUZZI** (DE LUCCI, DEI LUZZI MUNDINUS) (1270?–1326), Italian physician and the founder of modern anatomy. He reintroduced the study of body structure from human dissections after this practice had been abandoned for about 1,700 years. Born in Bologna in the latter part of the 13th century, he received his medical training in the famed university of that city. After graduation he taught and studied anatomy and surgery at his alma mater while carrying on active practice in both medicine and surgery. He died at Bologna in 1326.

Anatomy, previous to Mondino's time, was taught from the books of Galen and occasionally from the dissection of pigs or monkeys. It was Mondino's great service that he revived the practice of human dissection for study as well as student demonstration. His *Anathomia* was written in 1316 and became the standard text on the subject for more than 200 years. It was first printed in Pavia in 1478 and went through about 40 editions. In this book, the teachings of Galen are perpetuated with no attempt to challenge or change them. It instructs the student in the technique of dissection as well as in the description of the parts. Adaptation of structure to function, morbid changes and even therapeutic suggestions are added to the anatomical descriptions.

Mondino wrote other books on medicine and surgery and commentaries on Hippocrates and Galen, but his assured place in the history of medicine rests upon his classic little treatise on anatomy and upon the initiation of human dissection upon which it is based.

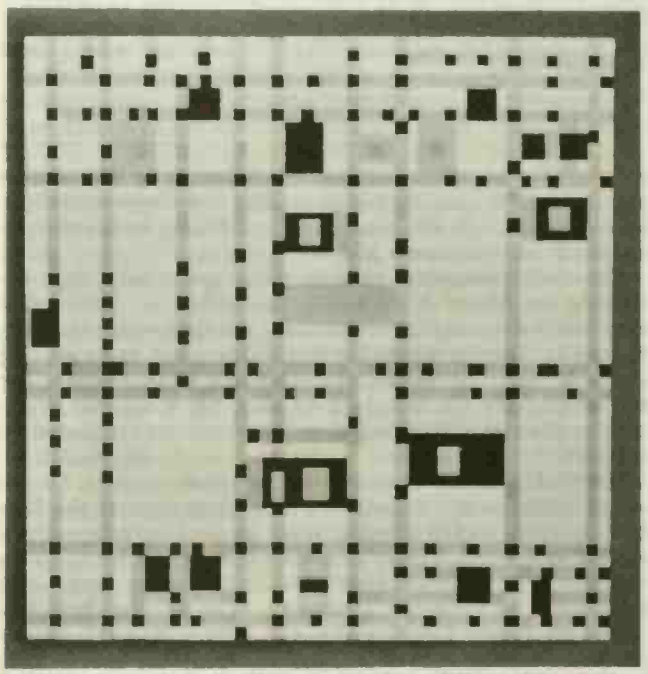
**MONDRIAN, PIET** (PIET CORNELIS MONDRIAAN) (1872–1944), Dutch painter, critically regarded as one of the purest nonobjective painters, was born in Amersfoort on March 7, 1872.



BY COURTESY OF THE MUSEUM OF MODERN ART, NEW YORK, PHOTOGRAPH BRUCE LONDON

"BROADWAY BOOGIE WOOGIE," OIL ON CANVAS, BY PIET MONDRIAN (1942–43). IN THE MUSEUM OF MODERN ART, NEW YORK

He received early instruction at home from his father, who was an amateur painter, and then attended the Amsterdam Academy of Fine Arts for three years. He achieved moderate success with his early landscapes, which emphasized mass and absence of detail, but in later years he drifted away from traditional techniques and began to explore the realm of abstractions. In 1910 he moved to Paris, where he came under the influence of French cubists. He developed an antipathy for curved lines, and his compositions were notable for their vertical and horizontal lines, which formed crosses and rectangles. In 1914, with Theo van Doesburg, he founded the Dutch de Stijl group of painters and architects, with whom he worked in the Netherlands for the next six years. On his return to Paris in 1920 he explained "neoplasticism" in a published report. Three years later he formed the nucleus of an abstractionist group. He left Paris for London at the start of World War II, and went to the U.S. in 1940. He died in New York city on Feb. 1, 1944.

Mondrian's influence may be felt in European architecture and in general trends in design. His pictures hang in museums in New York, Philadelphia and Buffalo and at Yale university, as well as in Amsterdam, The Hague, Dresden and Hanover. In 1943 the

Museum of Modern Art in New York city acquired his composition entitled "Broadway Boogie-Woogie," which became a source of controversy in professional circles; his "Composition in White, Black and Red" also is there. A representative showing of his work was held at the Museum of Modern Art in 1945.

**MONEL.** "Monel" is the registered trademark of the International Nickel Co., Inc., for a group of nickel-copper alloys, the first of which was developed in 1905, containing about 66% nickel and 31.5% copper, with small amounts of iron, manganese, carbon and silicon, and now designated Monel Alloy 400.

The alloy can be melted readily in all types of furnaces; is nickel-white in colour; has good mechanical properties; is highly resistant to corrosion under saline, sulfuric acid, and other reducing conditions; can be fabricated readily by hot and cold working, machining, and welding; is available in all commercial forms; and has more than 700 uses in the chemical, petrochemical, petroleum, chlor-alkali, pulp and paper, marine, and other industries. Its corrosion rate is low in moist atmosphere, fresh and sea water, and neutral and alkaline salt solutions including chlorides, carbonates,

*Important Properties of Monel Alloy 400*

| | |
|---|---|
| Density, g/cc at 20° C. (68° F.) | 8.84 |
| Melting range, ° C. | 1,300–1,350 |
| Modulus of elasticity (tension), lb. per square inch | 26,000,000 |
| Tensile strength, lb. per square inch | 80,000–150,000 |
| Elongation, percent | 50–10 |
| Thermal expansion, cm/cm/° C., 25°–100° C. | 0.000014 |
| Thermal conductivity, cal./sq. cm/cm/° C./sec.; 0°–100° C. | 0.062 |
| Electrical resistivity, microhm-cm | 48.2 |
| Hot working range, ° C. | 700–1,175 |

sulfates, nitrates, and acetates, and in nonoxidizing salt solutions such as zinc chloride, ammonium sulfate and aluminum sulfate; but is high in nitric and other strongly oxidizing acids and ferric and cupric salts, sulfurous acid, and halogens.

Important commercial varieties which are equally corrosion-resisting are Monel Alloy K-500, age-hardenable nickel-copper alloy which contains 3% aluminum and was the first age-hardening nickel alloy having strength and ductility equal to many alloy steels; Monel Alloy R-405, free-machining nickel-copper alloy; and Monel Alloy 403, nickel-copper alloy, which is higher in copper than the other varieties of nickel-copper alloys and is used for nonmagnetic applications. (W. A. Mu.)

**MONEMVASIA** (anc. Minoa), a Greek town in Laconia *nomos* (department), lies on the southeastern coast of the Peloponnese, at the foot of a rock crowned by the ruins of a medieval fortress and a 14th-century Byzantine church, and joined to the mainland by a causeway, from which it derives its name, which means "city of the single approach." The ruins of Epidaurus Limera are nearby (*see* Epidaurus). Pop. (1961) 487 (mun.). The island is about a mile long, and its cliffs rise to about 600 ft. During the Slav incursions into the Peloponnese it was a place of refuge for Greeks from Laconia, and it became one of the principal fortresses and commercial centres of the Levant in the middle ages. Its name, in various forms (It. Malvasia; Fr. Malvoisie; Eng. Malvesie or Malmsey), became familiar throughout Europe from its extensive trade in a special wine, mainly imported from the Cyclades and Crete.

In the 6th century the Byzantine emperor Maurice raised it to an independent bishopric, and later emperors, notably Andronicus II in 1310, granted it special privileges. It was captured after a three years' siege by Guillaume de Villehardouin in 1248, but restored to the Byzantines in 1262. After the Turkish conquest of Greece it placed itself first under the papacy (1460–64), and then under the Venetians, who were forced to cede it to the Turks in 1540.

In 1689 it was the only town of the Peloponnese which held out against the Venetian, Francesco Morosini, though his successor Giovanni Cornaro reduced it by famine in 1690. In 1715 it again capitulated to the Turks; but it was the first fortress to fall to the Greeks in the War of Independence in 1821.

**MONET, CLAUDE** (1840–1926), French painter, a leader in the practice of open-air painting and one of the chief founders of Impressionism, was born in Paris on Nov. 14, 1840. The family moved to Le Havre about five years after. As a child, he much preferred excursions by the sea to the schoolroom, where he drew cartoons of his teachers. By the age of 15 he had gained a local reputation and a small income as a caricaturist; but it was not until meeting Eugène Boudin, the marine painter from Honfleur, that he began painting the sea and sky he so much loved.

Monet first visited Paris in 1859–60, where he was impressed by the paintings of Charles Daubigny and Constant Troyon. To his family's annoyance, he refused to enroll in the École des Beaux-Arts, but frequented the haunts of the advanced artists and worked at the Académie Suisse, where he met Camille Pissarro. This informal training was interrupted by a call to military service in Algeria. He was excited by the African light and colour, but returned to his family's home in Sainte-Adresse (near Le Havre) in 1862 because of illness. Again he painted the sea with Boudin, and met the Dutch marine painter Johann Jongkind. Later that year, and in 1863, he continued his study in Paris, this time with the academician Charles Gleyre, in whose atelier he met Frédéric Bazille, Alfred Sisley and Pierre A. Renoir. After disagreements with their master, the group departed for the forest of Fontainebleau where, two years later, at Chailly, Monet was to paint one of his best known early works, "The Picnic" ("Déjeuner sur l'Herbe"), in the spirit of Edouard Manet and Gustave Courbet, both of whom he already knew and admired. It was also during this period—sometime between 1858 and 1871—that Monet discovered Japanese prints, the decorative flatness of which was to play such an important role in the development of modern painting in France.

By 1872 Monet's direction was clear. He had settled in the Seine village of Argenteuil with his wife Camille and his five-year-old son Jean. His painting was already mature, and he had met his future dealer, Durand-Ruel. He had battled with changing outdoor light at Le Havre and Honfleur, in England and Holland, on the Seine and in the forest. He was also known for figure and still-life painting. In 1867, moreover, he had finished a huge figure composition, the "Women in the Garden," entirely in the open air. During his London visit (1870–71) he had seen the outdoor oil studies of John Constable and the romantic landscapes of J. M. W. Turner. He may have known James Whistler's early "Nocturnes." By 1874 Monet's radical art had become both a rallying point and a focus of attack; his "Impression," when shown in the first large exhibition of the expanding group of insurgent painters, caused them all to be labeled by the press, in derision, as Impressionists.

During the 1870s the river, rather than the sea, became Monet's primary subject. Already in 1868 he had begun the sequence of impressions of the Seine which formed a major part of his work before 1900. At Argenteuil, and later at Vétheuil, he constantly sought a more direct perceptual response to the changing appearances of nature, thus breaking sharply with the studio-conceived landscape painting of the past. In the 1880s, after Camille's death, he painted both the river and the seacoast, striving to reconcile first impressions with colour harmony, expressive manipulation of pigment and composition. Monet moved to his final home at Giverny with his second wife, Alice Hoschedé, in 1883. It was there, after 1890, that he systematized his method of developing several studies of the same motif in series, changing canvases with the light or as his interest shifted. These "series" were usually dated and often exhibited, in groups: "Poplars" (1890–91), "Haystacks" (1891), "Rouen Cathedrals" (1894), "Mornings on the Seine" (1896–97), "Scenes of the River Thames" (1899–1904), "Venice" (1908), etc. The most renowned of the works identified with Giverny, however, were those of the unique "water garden" which Monet had created by diverting the tiny Epte river. Before long paintings of water lilies, irises, weeping willows and his Japanese bridge could be found in most of the major art collections and museums of the world along with his other famous works. The last years, though hampered by failing eyesight, were almost entirely devoted to these "water landscapes." During

World War I, encouraged by his friend Georges Clemenceau, Monet planned a gift to the French government. He died on Dec. 5, 1926, before it was completed; but the following spring a series of large paintings of the garden were finally installed in two oval rooms in the Orangerie of the Tuileries.

**MONETA, ERNESTO TEODORO** (1833–1918), Italian patriot, journalist, pacifist and winner of the Nobel peace prize, was born in Milan on Sept. 20, 1833. Having taken part in the Milanese rising of March 1848 against Austrian rule, he emigrated to Piedmont after the final Austrian victory over Sardinia-Piedmont in 1849 (*see* ITALIAN INDEPENDENCE, WARS OF) and began studies at the military academy of Ivrea. He served in the war of 1859 in a corps of mountain troops organized by Garibaldi, in the campaign of 1860 in southern Italy and in the war of 1866 as an officer in the Italian army. In 1867 he resigned from the army to become editor in chief of the democratic Milanese newspaper *Il Secolo*, with which he remained till 1896. Impressed by the suffering that he had seen during his military career, Moneta in 1887 founded the Unione Lombarda per la Pace e l'Arbitrato, on the lines of the International Peace society organized in England by Hodgson Pratt, to promote disarmament, the formation of a league of nations and the settlement of international disputes by arbitration. To propagate his ideas, he launched a periodical *La Vita internazionale*, in 1898. The Nobel peace prize for 1907 was shared between Moneta and Louis Renault.

Moneta, however, was never ready to sacrifice his notion of justice to his pacifism. In 1911 he supported the impending Italian occupation of Libya (*see* ITALO-TURKISH WAR) as a means of civilizing a territory misruled by the Turks, and in 1915 he advocated Italian intervention in World War I against Austria-Hungary. Moneta died in Milan on Feb. 10, 1918.

**MONETARY AGREEMENT,** an agreement between countries concerning monetary matters of common interest to them. A special form of monetary agreement is that by which two or more countries adopt a common regulation of their currencies and thus create a monetary union.

An outstanding example was the Latin Monetary union founded in 1865 that embraced France, Belgium, Switzerland, Italy and later Greece. Each country kept its own nomenclature for its currency, France, Belgium and Switzerland terming their monetary unit the franc, Italy the lira, Greece the drachma. In 1873, because of the depreciation of silver, all the members of the union agreed to limit the coinage of new silver five-franc pieces, thus dropping the double standard of gold and silver to which they originally adhered, and placing their currency virtually upon the gold standard. All public offices of the member states were obliged to accept the union currency in payment. Subsidiary currency (silver token money ranging from 20 centimes to 2 francs) remained national, *i.e.*, was not union currency, nor were bank notes recognized as such. World War I broke up the Latin Monetary union in fact, if not in name.

Another important monetary union of the same type was the Scandinavian union, comprising Sweden, Norway and Denmark. There the national monetary units had a common name, the krone, or krona. The union was formed between Sweden and Denmark in 1873, and Norway joined two years later. The monetary union among the Scandinavian countries was much closer than that among the Latin countries. It embraced all subsidiary currency issued by the participant countries. The foreign exchange quotations were discontinued and the whole region could be considered, so far as monetary matters were concerned, as one country. During World War I the union broke up *de facto*, and was never revived. *See* also INTERNATIONAL PAYMENTS; STERLING AREA; INTERNATIONAL MONETARY FUND.

**MONEY,** the medium in which prices are expressed, debts discharged, goods and services paid for and bank reserves held. When used in the sense of the money supply, the term is synonymous with circulating medium and may be regarded as comprising demand deposits and common money or currency (q.v.); *i.e.*, paper money issued by the government, bank notes and coins. The term is used still more broadly to embrace money that does not enter into hand-to-hand circulation. This applies to the standard money, often gold, which may be held as a basic monetary reserve without at any time entering into general circulation. In the United States it includes gold certificates that constitute the legal reserves of the federal reserve banks. The term may even be extended to include abstract units that have been employed at different times for stating certain prices, the best-known example being the guinea, which is still used in England for stating certain types of monetary payments though it no longer circulates as part of the coinage. The expression "near-money" is sometimes used to denote liquid assets, such as time deposits and short-term government obligations, which are regarded as possessing some of the important characteristics of money and as having significant effects on the working of the monetary system.

The difficulty of arriving at a single clear-cut definition of money has led economists to describe money in terms of the functions it performs. The British economist Sir Ralph Hawtrey stated: "Money is one of those concepts which, like a teaspoon or an umbrella, but unlike an earthquake or a buttercup, are definable primarily by the use or purpose which they serve." (*Currency and Credit*, 3rd ed., Longmans, Green & Company, New York, 1928.) Alternatively, it may be said that money is anything, regardless of its physical or legal characteristics, that customarily and principally performs certain specified functions. Many writers, singling out the medium of exchange function as paramount, define money as synonymous with circulating medium. Others extend the definition to include reserve money, abstract units of account and even near-money.

The functions of money are closely interrelated, but it is nevertheless useful to differentiate among them. The most familiar is that of medium of exchange, whereby goods and services are paid for and debts and other contracts discharged. Money is also the unit of account, in which records are kept, costs computed and values compared. It is a means of stating the prices of goods and services and of expressing debts, salary and wage agreements, rents, insurance obligations and innumerable other contracts. The third major function of money is to serve as a reserve of ready purchasing power. Money is the only completely liquid asset. Ownership of a cash balance in the form of currency or demand deposits makes it possible to act quickly in matters calling for the payment of money. The convenience and other benefits conferred by the possession of ready cash are entirely different from the more or less pathological considerations that motivate the miser.

Certain functions of money that were of major importance at

one time declined, while other functions became more important, and entirely new functions arose. For example, the use of money as a store of value was important in earlier societies but became of relatively little consequence in more advanced economies. People now prefer to store values in savings deposits, insurance policies or securities where the unit-of-account function of money (particularly as a standard of deferred payments) is of primary concern. With the rise of commercial banking and central banking, came a corresponding increase in the importance of the use of money as reserves of the banking system.

Money is unique among economic goods because it is usually not regarded as wealth (though gold or other commodity money should be included as part of wealth) but as a device for exchanging and measuring wealth. An increase in the quantity of money in a country does not necessarily constitute an increase in the country's wealth. More money results in higher prices or greater liquidity but does not necessarily, except possibly through some roundabout process, mean greater wealth. Money is neither a production good nor a consumption good. It is sometimes given the rather abstract title of *numéraire*, something used for counting or expressing relationships among other things. The value of money in the sense of what it exchanges for is ordinarily measured in terms of index numbers of prices. Changes in the value of money are shown as the reciprocal of percentage deviations of the index from some established base. A rise of 100% in the index number of prices would signify that the value of money, *i.e.*, its purchasing power, had fallen by one-half. (*See* INDEX NUMBERS.)

**Origin and Development of Money.**—Scores, perhaps hundreds, of different objects have served as money at one time or another, including such things as slaves, gunpowder and the jawbones of pigs. Perhaps the heaviest money ever used was the stone money of the island of Yap in the South Pacific, and the lightest, the feather money of the New Hebrides. For centuries, salt circulated as money among the natives of Ethiopia without being supplanted by the gold or silver coins of the traders with whom the Ethiopians came in contact.
